

Division I

Pteridophyta (Vascular Cryptogams)

Plants of soil, in or floating on the water, or growing as epiphytes on trees or rocks. Plants belonging to this group may resemble what are popularly considered fern-like, but may also be moss-like, rush-like, or quill-like. They reproduce by spores, and not by embryos, and have no true flowers. An alternation of generations is characteristic of this division: a small green or inconspicuous *prothallium* (gametophyte) represents the haploid or sexual generation bearing antheridia and archegonia; the mostly large *sporophyte* represents the diploid or asexual generation, and has usually roots, stems, and leaves of diverse shapes and forms, with reproduction asexually by means of spores produced within *sporangia* or spore-cases (*sporocarp*). The spores may be all alike, or in some families of two types (minute microspores and larger megaspores).

About 9,000 species are known.

The following key to the main orders of Pteridophyta is adapted partly from Morton's treatment in Gleason's *New Illustrated Flora*, and partly from Fernald's eighth edition of *Gray's Manual*.

- a. Plants free-floating, small, moss-like; sporangia on the lower side, enveloped by stalkless or nearly stalkless sporocarps Fam. SALVINIACEAE in Order Filicales (p. 16)
- a. Plants rooting in the soil, or growing on rocks, bluffs, trees, or submerged in water b
- b. Stems jointed; the leaves whorled and united into a sheath; sporangia arranged in a cone-like strobilus at the tip of the stem Order EQUISETALES (p. 11)
- b. Stems not jointed; the leaves not united into a sheath; sporangia either in the axils of leaves, or at the base of the leaves, or borne on the back or margin of the leaves, or in spike-like or branched special fronds c
- c. Leaves small and overlapping like shingles, or grass-like and capping a short thickened stem. d
- d. Leaves grass-like and elongated; stem unbranched; sporangia sunken in the leaf-base. Order ISOETALES (p. 10)
- d. Leaves small, less than $\frac{1}{2}$ inch (13 mm.) long; stems branched; sporangia not sunken in the leaf-base e
- e. Leaves in 4-16 ranks, without a ligule; sporangia-bearing stems cylindrical (terete); sporangia all alike, minute, numerous Order LYCOPODIALES (p. 7)
- e. Sterile leaves in 4-6 ranks, with a transverse ligule at base; sporangia-bearing stems more or less 4-sided; sporangia consisting of 4 large megaspores or many minute microspores Order SELAGINELLALES (p. 8)
- c. Sterile leaves either not overlapping, or lacking sporangia arranged in axils of or at the bases of leaves, or borne on the back or margin of the leaves, or in spike-like or on branched special fronds, or in special hard spore-cases f
- f. Fronds (leaf-like part) with 4 leaflets arranged like a 4-leaf clover Fam. MARSILEACEAE in Order Filicales (p. 17)
- f. Fronds otherwise g

- g. Fertile fronds or fertile portions of the fronds similar to the sterile fronds Fam. POLYPODIACEAE in Order Filicales (p. 20)
- g. Fertile fronds or fertile portions of the fronds quite unlike the sterile frond or fronds h
- h. Sterile (leaf-like) portion of frond simple and without any teeth or lobes; the fertile consisting of a simple 2-rowed spike of sporangia Order OPHIOGLOSSALES (p. 15)
- h. Sterile (leaf-like) frond or portion of frond more or less divided; fertile frond or portion of frond variously divided i
- i. Leaves divided into a sterile lower half and a fertile upper panicle; leaves fleshy; leaves not coiled in bud, with sheathing leaf-bases; sporangia without an annulus, nearly stalkless Order OPHIOGLOSSALES (p. 14)
- i. Leaves not fleshy; leaves usually coiled in bud, without sheathing leaf-bases; sporangia with an annulus, short- or long-stalked Order FILICALES (p. 18)

The most modern classification discards the division Pteridophyta, and divides the above orders into the following natural alliances:

Class Filicineae:

Phylum: Lycopsida	{ Lycopodiales Selaginellales Isoetales
Phylum: Sphenopsida	{ Equisetales
Phylum: Pteropsida	{ Ophioglossales Filicales

KEY TO FERNS AND FERN ALLIES

- a. Whole plant floating free on water Water Fern Family (Salvinaceae) (p. 16)
- a. Some part of the plant either rooted in the soil, on land, or in water, or growing on rocks or trees, not free floating b
- b. Stems conspicuously jointed and finely many-ridged Horsetail Family (Equisetaceae) (p. 11)
- b. Stems not jointed and rigid, with green leaf-blades or leaf-like fronds c
- c. Leaves small, scale-like, moss-like, needle-like, less than 2 cm. long, or, if longer, quill-like d
- d. Leaves quill- or needle-like, or in a single rosette Quillwort Family (Isoetaceae) (p. 10)
- d. Leaves scale- or moss-like, numerous, often overlapping e
- e. Leaves pale or bright green and thin on delicately creeping stems, or leaves dull, dark, or gray-green, closely overlapping, thread-like, bristly tipped, the individual stems (excluding the leaves) only 0.2–1.2 mm. thick; stems and branches at most 5 cm. tall Spikemoss Family (Selaginellaceae) (p. 8)
- e. Leaves otherwise, or dark green, the individual stems thicker; stems or erect branches usually 7–25 cm. tall Clubmoss Family (Lycopodiaceae) (p. 7)
- c. Leaves (at least the sterile blades) larger, flattened, and expanded, more than 2 cm. long, not quill-like f
- f. Leaves divided into 4 fan-shaped leaflets, like a 4-leaf clover Pepperwort Family (Marsileaceae) (p. 17)
- f. Leaves not divided into 4 fan-shaped leaflets g
- g. At least the green leaf-like part of plant (frond) simple, not toothed or lobed h
- h. Green leaf-like part long and narrow, long-tapering at tip, the midrib distinct 22. Walking fern (CAMPTOSORUS in Polypodiaceae)
- h. Green leaf-like part short-pointed or rounded at tip, the midrib none or obscure 6. Adder's Tongue (OPHIOGLOSSUM in Ophioglossaceae)
- g. Green leaf-like part of plant (frond) shallowly or deeply lobed, or divided into distinct units or segments (pinnae and pinnules) i
- i. Leafy part lobed, but the innermost portion (base) (part toward midrib) of at least some of the lobes connected with one another by a continuous leafy connection j
- j. Stipe (main stem) and rachis (central axis between leafy part) split into 3 main branches 12. PTERIDIUM in Polypodiaceae

- j. Stipe and rachis straight or one main axis *k*
- k. Main leafy part with a conspicuous long tail-like tip 21. *ASPLENIUM* (*A. EBENOIDES*,
GRAVESII, and *PINNATIFIDUM*) in Polypodiaceae
- k. Main leafy part lacking a conspicuous long tail-like tip, or, if somewhat long-tailed at tip,
either at least the greatest part of the leafy area is deeply divided, or the leafy area 10–40 cm.
wide *l*
- l. Leafy part 1–7 cm. wide, each of the lobes 2–7 mm. wide; plants growing on rocks, bluffs,
or trees 17. *POLYPODIUM* in Polypodiaceae
- l. Leafy part 10–40 cm. wide, each of the lobes 10–80 mm. wide; plants growing on the
ground in soil *m*
- m. Upper side of leaf segments finely hairy (use lens); veins of segments simple or forked,
not joining in a net (reticulate) (use lens or hold up to light) 26. *THELYPTERIS*
HEXAGONOPTERA in Polypodiaceae
- m. Upper side of segments mostly glabrous (without hairs); veins netted, joining *n*
- n. At least some of the segments (usually lower ones) obviously lobed or with wavy
margins, but without fine teeth on margin itself; leaf segments, at least in the upper
half of leaf-blades, opposite 19. *ONOCLEA* in Polypodiaceae
- n. None of the segments obviously lobed or with wavy margins, but the margins actually
have fine teeth; leaf segments all alternate 20. *WOODWARDIA AREOLATA* in Polypodiaceae
- i. Leafy part of plant variously divided into distinct segments completely cut to the main stem (rachis) *o*
- o. Leafy part of plant white-powdery on lower surface 15. *NOTHOLAENA*
- o. Leafy part of plant of other colors on lower surface but not white-powdery *p*
(see alternate key for completely sterile plants on p. 5)

KEY TO FERTILE (SPORE-BEARING) PLANTS

- p. Fertile (spore-bearing) part of plant on a special branch completely or partly separated
from the sterile leafy part, or if not on a special branch, at least separated in some manner
from the leafy part *q*
- q. Roots fleshy; leafy part broadly triangular, divided into three main parts 5. *BOTRYCHIUM*
in Ophioglossaceae
- q. Roots fibrous; leafy part once divided into main segments arranged stepladder-like one
above the other (pinnae) or twice compoundly divided (bipinnate) *r*
- r. Leafy part twice compoundly divided (twice pinnate), the main branches and segments
well separated from one another; fertile parts, when present, at summit of leafy
branch 10. *OSMUNDA REGALIS* var. *SPECTABILIS* in Osmundaceae
- r. Leafy part once divided into main segments arranged stepladder-like and crowded one
above the other; fertile parts, when present, either on branches separate from and
shorter than the leafy branches, or interrupting a regular sequence of sterile segments
on a leafy branch *s*
- s. Tufts of woolly hair present at the base of most leaf divisions (pinnae); margins of
lobes of leaf divisions loosely fringed with hairs 10. *OSMUNDA CINNAMOMEA* in Osmundaceae
- s. Tufts of wool not present at the base of main leaf divisions (pinnae); margins of
lobes of leaf divisions without hairs *t*
- t. Smallest segments or pinnules mostly 2–4 mm. wide; veins of leaf segments
simple, free; main pinnae long-pointed (acuminate) at tip; fertile parts arising
on branches separate from and shorter than the leafy branches 18. *MATTEUCCIA*
in Polypodiaceae
- t. Smallest leaf segments or pinnules mostly 4.5–8 mm. wide; veins of leaf segments
forking; main pinnae blunt or short-pointed at tip; fertile parts interrupting a
sequence of leafy sterile segments on the leafy branch 10. *OSMUNDA CLAYTONIANA*
in Osmundaceae
- p. Fertile (spore-bearing) part (fruit dots) of plant usually appearing on the under surface or
along or near the margins of the leafy part (frond) *u*
- u. Leaf-blade broadly triangular, compoundly divided into three large main divisions (three
times divided or nearly so) 12. *PTERIDIUM*
- u. Leaf-blade otherwise, not alternately divided *v*

- v. Stipe (main leaf-stalk) and rachis (central axis of leaf-blade) dark brown, reddish- or purplish-brown or black mostly from end to end w
- w. Stipe and rachis mostly lacking hairs or scales x
 - x. Stipe and rachis remaining simple, straight, and unbranched; leaf-blade once-pinnate, the divisions stepladder-like one above the other, the lowermost pinnae at most deeply lobed, but not completely separated at their base 21. ASPLENIUM
 - x. Stipe and rachis either forking into two main branches above or alternately branched, or the lowermost main leaf divisions composed of more than one pinnule y
 - y. Ultimate leaf divisions (pinnules) toothed or lobed; stipe and rachis either forking into two main branches above or the lateral branches of rachis alternate 13. ADIANTUM
 - y. Ultimate leaf divisions (pinnules) lacking teeth; stipe straight, the lower main leaf divisions (pinnae) divided into 3 or more segments (pinnules) from opposite branches 14. PELLAEA GLABELLA
- w. Stipe and rachis mostly with hairs z
 - z. Leaf-blade once-pinnate, all the divisions remaining simple and undivided, even the lowermost pinnae only deeply lobed at most and not completely separated at their base. 21. ASPLENIUM
 - z. Leaf-blade twice or thrice pinnate, or at least the lowest main divisions (pinnae) of 3-9 segments (pinnules) I
 - 1. Ultimate leaf-divisions (pinnules) 5-10 mm. wide; leaf-blade simply pinnate above, the lowermost pinnae with 3-9 pinnules 14. PELLAEA ATROPURPUREA
 - 1. Ultimate leaf-divisions (pinnules) at most 1.5 mm. wide; leaf-blade twice to thrice pinnate 16. CHEILANTHES
- v. Stipe (main leaf stalk) and/or rachis (central axis of leaf-blade) at least green or only pale brown in upper half, the lower half green, pink, straw-colored or pale brown, but never dark brown or black from one end to the other 2
 - 2. Main leaf-divisions (pinnae) simple, not lobed nor divided to their midribs, at most only toothed. 3
 - 3. Stipe with conspicuous chaffy scales; leaf-divisions firm and thickish; some of leaf-blades of last year lying on the ground. 28. POLYSTICHUM
 - 3. Stipe mostly lacking hairs or scales, presenting a smooth appearance; leaf divisions thin, delicately membranous; all leaf-blades upright 23. ATHYRIUM PYCNOCARPON
 - 2. Main leaf divisions (pinnae) deeply lobed or divided to their midribs 4
 - 4. No conspicuous hairs or chaffy scales present on stipe and rachis 5
 - 5. Main leaf-divisions (pinnae) obviously alternate, 2-6, obviously long-stalked (petiolate); frond 1-7 (-17) cm. long 21. ASPLENIUM RUTA-MURARIA var. CRYPTOLEPIS
 - 5. At least the lower and middle main leaf-divisions (pinnae) opposite, or nearly or chiefly opposite, the uppermost often alternate, 9-40, stalkless (sessile) or only very short-stalked (petiolate); frond mostly 7-90 cm. (rarely as little as 2 or as much as 100 cm.) long 6
 - 6. Main leaf-divisions (pinnae) divided all the way to the midribs, or if not quite so divided, at least some of the ultimate pinnules unequal in size and shape; fruit dots (sori) on under side of leaf roundish; membrane (indusium) over fruit dots cup-shaped. 25. CYSTOPTERIS
 - 6. Main leaf-divisions (pinnae) deeply lobed but not divided all the way to their midribs, the lobes connected from base to tip by continuous green tissue, the ultimate lobes all of about the same size and shape; fruit dots and membrane over them elongated, longer than broad, or rounded or kidney-shaped 7
 - 7. Ultimate leaf-divisions minutely hairy-fringed on margins; fruit dots rounded or kidney-shaped (reniform); rootstocks slender, creeping; plants of wet meadows and spring-fed wet ground 26. THELYPTERIS PALUSTRIS var. PUBESCENS
 - 7. Ultimate leaf-divisions not hairy-fringed on margins; fruit dots elongated, somewhat curled, longer than broad; rootstock thickish; plants of rich woods 23. ATHYRIUM THELYPTEROIDES
 - 4. Obvious scales or tiny hairs or glands, or both, present on stipe and rachis, at least in early stage of growth 8
 - 8. Tiny hairs and glands, but no scales, present on stipe and/or rachis; fruits dots appearing at the margin of the smallest leaf-divisions 11. DENNSTAEDTIA
 - 8. Obvious scales present on some part of the stipe, either when young or at maturity; hairs and glands present or absent on stipe and/or rachis; fruit dots appearing on the under surface of the ultimate leaf-divisions 9
 - 9. Tiny long-stalked glands present on rachis (axis of leafy blade): indusium attached beneath the sorus 24. WOODSIA

9. No long-stalked glands on rachis, although other kinds of glands or hairs may be present; indusium otherwise 10
10. Hairs present on upper and lower surfaces or veins of leaf-divisions 11
11. Ultimate leaf-divisions minutely hairy-fringed on margins; fruit dots rounded or kidney-shaped (reniform); rootstocks slender, creeping; plants of wet meadows and spring-fed ground 26. *THELYPTERIS PALUSTRIS* var. *PUBESCENS*
11. Ultimate leaf divisions not hairy-fringed on margins; fruit dots elongated, somewhat curved, longer than broad; rootstock thickish; plants of rich woods 23. *ATHYRIUM THELYPTEROIDES*
10. Hairs absent on upper and lower surfaces or veins of leaf divisions 12
12. Fronds not evergreen, rather thin and nearly membranaceous; indusium with a linear attachment, thin and inconspicuous 23. *ATHYRIUM FILIX-FEMINA*
12. Fronds evergreen, rather thick; indusium conspicuous 27. *DRYOPTERIS*

ALTERNATE KEY TO COMPLETELY STERILE SPECIMENS

(substitute for o. on p. 3 and continue)

- p. Stipe and rachis either forking into 2 main branches above or the lateral branches of rachis alternate 13. *ADIANTUM* in Polypodiaceae
- p. Stipe and rachis either straight, or split into 3 main branches q
- q. Blade as a whole broadly triangular and 3-parted r
- r. Stipe round, soft and brittle, easy to break, root fleshy 5. *BOTRYCHUM* in Ophioglossaceae
- r. Stipe not round, fibrous, hard to tear, root fibrous 12. *PTERIDIUM* in Polypodiaceae
- q. Blade as a whole not 3-parted s
- s. Blade once pinnate, all the divisions simple t
- t. Stipe and rachis dark brown, reddish- or purplish-brown or black mostly from end to end u
- u. Minute teeth on edges of leaf-divisions 21. *ASPLENIUM*
- u. No teeth present, the margins entire 14. *PELLAEA GLABELLA*
- t. Stipe and/or rachis at least green or only pale brown in upper half, the lower half green, pink, straw-colored, or pale to dark brown, but never completely dark brown or black from one end to the other v
- v. Dwarf ferns with leafy blade only 4–25 cm. long; leaf-blade at most 4.5 cm. wide 21. *ASPLENIUM*
- v. Large ferns with leafy blade mostly 25–110 cm. long; leaf-blade 5–20 cm. wide w
- w. Stipe with conspicuous chaffy scales; leaf-divisions firm, thickish; some of leaf-blades of last year remaining next to the ground 28. *POLYSTICHUM*
- w. Stipe mostly lacking hairs or scales, presenting a smooth appearance; leaf-divisions thin, delicately membranous; all leaf-blades upright 23. *ATHYRIUM PYCNOCARPON*
- s. Blade more than once pinnate, at least the lower or lowermost pinnae (main horizontal divisions) divided, or all the pinnae deeply lobed (pinnatifid) or divided to their midrib into vertical divisions (pinnules) x
- x. Stipe and rachis dark brown, reddish- or purplish-brown or black mostly from end to end y
- y. Ultimate leaf-divisions (pinnules) 5–10 mm. wide; leaf simply pinnate above, or the lower and/or upper pinnae divided into 3–9 divisions 14. *PELLAEA*
- y. Ultimate leaf-divisions (pinnules) at least 1.5 mm. wide; leaf twice to thrice pinnate 16. *CHEILANTHES*
- x. Stipe and/or rachis at least green or only pale brown in upper half, the lower half green, pink, straw-colored or pale brown, but never a dark brown or black from one end to the other z
- z. Tufts of woolly hair present at the base of most leaf-divisions 10. *OSMUNDA CINNAMOMEA* in Osmundaceae
- z. No tufts of wool present at base of leaf-divisions 1
1. Main leaf-divisions (pinnae) all alternate, 2–6, and obviously long-stalked (petiolate); frond 1–7 (–17) cm. long 21. *ASPLENIUM RUTA-MURARIA* var. *CRYPTOLEPIS*
1. Without this combination of characters, the fronds either larger, or the main pinnae opposite, or, if alternate, the pinnae not long-stalked or more numerous 2
2. Leaf-blade twice or thrice pinnate, the main pinnae divided to their midribs into separate unconnected divisions (pinnules) 3

3. Ultimate leaf-divisions nearly entire, obviously well separated from one another, mostly 3-7 cm. long and 0.7-2 cm. broad 10. *OSMUNDA REGALIS* var. *SPECTABILIS*
3. Ultimate leaf-divisions mostly toothed or lobed, rather crowded, mostly much shorter and narrower 4
4. No conspicuous hairs or chaffy scales present on stipe and rachis at maturity 25. *CYSTOPTERIS*
4. Obvious scales or tiny hairs or glands, or both, present on stipe and rachis, at least in early stage of growth 5
5. Tiny hairs and glands, but no scales present on stipe and/or rachis 11. *DENNSTAEDTIA*
5. Obvious scales present on some part of the stipe, either when young or at maturity; hairs and glands present or absent on stipe and/or rachis 6
6. Tiny long-stalked glands present on rachis (axis of leaf-blade) 24. *WOODSIA*
6. No long-stalked glands on rachis, although other kinds of glands or hairs may be present 7
7. Fronds not evergreen, rather thin and nearly membranaceous 23. *ATHYRIUM FILIX-FEMINA*
7. Fronds evergreen, rather thick 27. *DRYOPTERIS*
2. Leaf-blade with the main pinnae deeply lobed (pinnatifid), but not divided to their midribs into disconnected separate divisions, the ultimate divisions remaining connected at least at the very base 8
8. Ultimate leaf-divisions with entire or nearly entire margins 9
9. No conspicuous hairs or chaffy scales present on stipe and rachis at maturity 10
10. Ultimate leaf-divisions minutely hairy-fringed on margins; rootstock slender and creeping; fronds not growing in a clump from a center; plants of wet meadows and moist spring-fed ground 26. *THELYPTERIS PALUSTRIS* var. *PUBESCENS*
10. Ultimate leaf-divisions not minutely hairy-fringed on margins; rootstocks thick; fronds growing in a clump from a center; plants of rich woodland 11
11. Main horizontal pinnae long-pointed at tip; veins of ultimate leaf-divisions simple, not forked 23. *ATHYRIUM THELYPTEROIDES*
11. Main horizontal pinnae blunt or short-pointed at tip; veins of ultimate leaf-divisions forked 10. *OSMUNDA CLAYTONIANA*
9. Obvious scales or hairs or glands or both present on stipe and rachis 12
12. Ultimate leaf-divisions minutely hairy-fringed on margins; rootstock slender and creeping; fronds not growing in a clump from a center 26. *THELYPTERIS PALUSTRIS* var. *PUBESCENS*
12. Ultimate leaf-divisions not minutely hairy-fringed on margins; rootstock thick; fronds growing in a clump from a center 13
13. Fronds conspicuously narrowed at base, the lowest main pinnae conspicuously shorter than those half way up; fronds numerous, growing around the center in a vase-like arrangement 18. *MATTEUCCIA*
13. Fronds slightly narrower at base, but the lowest main pinnae only slightly shorter than those half way up; fronds relatively few, grouped close to one another, but not arranged around the center in a vase-like manner 23. *ATHYRIUM THELYPTEROIDES*
8. Ultimate leaf-divisions toothed, either minutely or conspicuously 14
14. No scales or hairs present on stipe or rachis 25. *CYSTOPTERIS*
14. Either scales or hairs or both present on some part of stipe or rachis 15
15. Hairs absent on upper and lower surface or veins of leaf-divisions 16
16. Fronds not evergreen, rather thin and nearly membranaceous 23. *ATHYRIUM FILIX-FEMINA*
16. Fronds evergreen, rather thick 27. *DRYOPTERIS*
15. Hairs present on upper and/or lower surfaces or veins of leaf-divisions 17
17. Fronds triangular, the lowest pinnae obviously the longest 27. *DRYOPTERIS HEXAGONOPTERA*
17. Fronds broadly oblong-lanceolate or oblong, the lowest pinnae shorter than the others 23. *ATHYRIUM THELYPTEROIDES*

Order LYCOPODIALES

Fam. LYCOPODIACEAE (Clubmoss Family)

1. Lycopodium L. (Clubmoss)

- a. Leafy branches flattened, the erect ones forking and fan-like; leaves scale-like, greatly reduced in size, attached to stem for most of their length 4. L. TRISTACHYUM
- a. Leafy branches not appearing to be flattened; leaves obviously developed, although often moss-like or needle-like, loose b
- b. Plant tree-like; spores in modified leaf axils crowded into a cone (strobilus) at the tip of a branch 3. L. OBSCURUM var. DENDROIDEUM
- b. Plant erect to ascending, nearly unbranched or the stems loosely once- to few-forked; spores in axils of ordinary foliage leaves, not crowded into a cone c
- c. Leaves broadest above the middle, toothed; plant with loosely creeping, rooting, leafy bases 10-40 cm. long; groups of shorter leaves alternate with groups of longer leaves on stem . 2. L. LUCIDULUM
- c. Leaves broadest at base, nearly entire; plant with short rooting base 1-8 cm. long; all leaves of about same length 1. L. SELAGO var. PATENS

1. **Lycopodium Selago L. var. patens** (Beauv.) Desv. Fir Clubmoss Map 1
Lycopodium lucidulum var. *porophilum* (Lloyd & Underw.) Clute [P & S]; *Lycopodium porophilum* Lloyd & Underw. [G]
Forming spores July-October.
Shaded crevices of usually La Motte sandstone bluffs, south-eastern Missouri Ozarks.
Ranges from Newfoundland to Ontario and Minnesota south to Alabama and Missouri.

2. **Lycopodium lucidulum** Michx. var. **lucidulum** Shining Clubmoss Map 2
Under 15 x magnification it will be observed that the stomata appear as small whitish dots in this species on the lower surface only, whereas in *L. Selago* var. *patens* the stomata appear on both upper and lower surfaces of leaves.
Forming spores July-October.
Shaded crevices and ledges of La Motte and St. Peter sandstone bluffs, eastern Ozark region north to

Pike and west to Callaway counties, mostly near the Mississippi and Missouri rivers. North and west of St. Louis County and Jefferson County the locations are on St. Peter sandstone; the Ste. Genevieve and Madison County records are from La Motte sandstone.
Ranges from Newfoundland to Minnesota, south to South Carolina and Missouri.

3. **Lycopodium obscurum L. var. dendroideum** (Michx.) D. C. Eat. Map 3
Round-branched Ground Pine
Spores July-November.
Known only from Ste. Genevieve County, on shaded La Motte sandstone bluffs along upper reaches of River Aux Vases, 3½-4 mi. northwest of Avon, August 30, 1951, *Steyermark* 72506. The plants occur in a bed of sphagnum moss high on a steep bluff in a narrow ravine.
A specimen from Marion County ('Teajne's Conser.' [?], Hannibal, Dec. 15, 1909, *Rev. John Davis*) in the Mo. Bot. Gard. Herbarium, was un-

4 *Lycopodium tristachyum* (Ground Cedar)5 *Selaginella apoda*6 *Selaginella rupestris*

doubtedly collected in a conservatory or greenhouse from a cultivated plant, but is recorded here in order to eliminate it as a future source of error in citation of a possible native station.

Ranges from Labrador to Alaska, south to Georgia, Tennessee, Missouri, and Montana.

The isolated occurrence of this more northern species may be interpreted as a survivor or relict which has migrated southward into the Missouri Ozarks during one of the interglacial stages of the Pleistocene period.

4. ***Lycopodium tristachyum*** Pursh

Ground Cedar, Ground Pine

Map 4

Spores July–September.

Known only from dry wooded edge of bluffs of

La Motte sandstone in pine woods in Ste. Genevieve County. Effort to relocate the plant at the Madison County station, where reported and presumably collected by *E. J. Palmer* near Mine La Motte, has failed. The only present known locality is at Pickle Springs, Ste. Genevieve County. Collections by *Kellogg 8718* and *Kellogg s.n.* are representative.

Ranges from Newfoundland to Minnesota, south to Georgia, Tennessee, and Missouri.

The collections have been identified by the latest monographer of the group, Miss Joan H. Wilce. They had been referred previously to *L. complanatum* var. *flabelliforme* Fern., differing from the latter in the well-developed ventral leaves, the bluish color of the sterile branchlets, and the many constrictions along the branchlets.

Order SELAGINELLALES

Fam. SELAGINELLACEAE (Spikemoss Family)

2. *Selaginella* Beauv. (Spikemoss)

Stems and branches delicately creeping or flattened; leaves pale or bright green, spreading, oval or ovate; wet limestone ledges and banks 1. *S. APODA*

Stems with erect branches; leaves gray-green, thread-like, closely spirally arranged; dry sandstone, granitic, or chert rocks, ledges, and glades 2. *S. RUPESTRIS*

1. ***Selaginella apoda*** (L.) Fernald

Map 5

Spores May–November.

On wet limestone bluffs, along wet banks and moist ground of spring branches flowing from calcareous rocks, and on wet ground of springy meadows fed by calcareous spring branches. Throughout the Ozark region north to the Missouri River. Of expected occurrence in the Ozark border counties just north of the Missouri River.

Ranges from Maine to Quebec and Wisconsin south to Florida and Texas.

2. ***Selaginella rupestris*** (L.) Spring

Map 6

Spores July–October.

Predominantly found on dry sandstone (La Motte, St. Peter, Roubidoux, and those of Mississippian and Pennsylvanian age) glades and open ledges, and on dry exposed chert and igneous (granite and porphy-

9 *Isoetes Butleri*

ritic trachyte) rocks. Mainly distributed in two areas: (1) eastern Ozarks north to Lincoln and Montgomery counties, and (2) unglaciated prairie on chert and sandstone of Mississippian and Pennsylvanian formations in southwestern Missouri. The Adair County reference, originally attributed to Missouri, should be eliminated. The data on the label read 'shaded damp hillside, Adair Co., Mo.,' and is in the Broadhead herbarium at the Missouri Botanical Garden Herbarium. No collector was indicated on the label. Dr. Tryon, who has recently monographed this group, has identified the specimen as one with which some *Selaginella Underwoodii* is mixed. Since

S. Underwoodii is a species of the western states, and the 'shaded damp hillside' is a habitat unlikely for *S. rupestris*, I agree with Dr. Tryon that the locality is taken from a mistaken or confused source. Therefore, this record should be ignored.

Ranges from Nova Scotia to Ontario and Minnesota, south to Georgia, Arkansas, and Oklahoma.

The plants are subjected to long spells of summer drouth and heat on the exposed sites where they grow. At such times the plants appear dried, brittle, and lifeless. However, they respond to the slightest moisture, and become soft, dull green, and lifelike again after a rain.

Order ISOETALES

Fam. ISOETACEAE (Quillwort Family)

3. *Isoetes* L. (Quillwort)

- a. Plants mostly aquatic, submerged in water or along the exsiccated margins of sink-hole ponds and ditches; leaves 1–2 mm. wide at the middle; megaspores with honeycomb network of narrow ridges; microspores smooth or nearly so 1. *I. ENGELMANNI*
- a. Plants usually growing in wet prairies or wet sandy or rocky glades; leaves 0.4–1.3 mm. wide at the middle; megaspores tuberculate; microspores spinulose or papillose *b*
- b. Bases of leaves dark chestnut-brown or blackish; leaves mostly 1–1.3 mm. wide at the middle; megaspores averaging 0.33 mm. in diameter; microspores 20–30 μ long, covered with spinules 2. *I. MELANOPODA*
- b. Bases of leaves usually pale or brown; leaves mostly 0.4–0.9 mm. wide at the middle; megaspores averaging 0.6 mm. in diameter; microspores 27–37 μ long, papillose 3. *I. BUTLERI*

1. *Isoetes Engelmanni* A. Br. var. *Engelmanni*

Map 7

This is a characteristic plant found partly or entirely submerged along the margins of sink-hole ponds in the eastern Ozark section. So far as known, the St. Louis County record is exterminated.

Ranges from Florida and Alabama, north to New Hampshire, New York, southern Indiana, southern Illinois, and eastern Missouri.

Usually much coarser in habit than the other species in Missouri, the leaves of *I. Engelmanni* average longer and broader and have a more coarsely cellular structure.

2. *Isoetes melanopoda* Gay & Durieu f. *melanopoda*

Map 8

Isoetes melanopoda Gay & Durieu [G], [P & S]
Wet open ground and wet swales. Scattered in

southern and eastern Missouri south of the Missouri River and locally in Jackson County.

Ranges from Illinois and Iowa, south to Missouri, Oklahoma, and Texas.

Isoetes melanopoda may further be distinguished from *I. Butleri*, which it closely resembles, by the brown-spotted instead of brown-lineolate usually larger sporangia (0.5–3 cm. instead of 0.6–0.7 cm. long).

Another form of the species, *I. melanopoda* f. *pallida* (Engelm.) Fern., with pale leaf-bases is to be expected in Missouri.

3. *Isoetes Butleri* Engelm.

Map 9

Wet prairies and wet places on rocky glades and ledges of bluffs. This is the commonest species in Missouri. It is found commonly in the western Ozarks

and unglaciated prairie section of southwestern Missouri, and in the Ozark border counties northeast to Lincoln County. It occurs on both sandstone and chert as well as limestone glades which are wet in spring and become dry and hot in the summer when the plants then disappear. The species is sometimes difficult to distinguish from young, similar-looking plants with erect, aciculiform leaves of *Eleocharis compressa*, *Nothoscordum bivalve*, and other glade plants with which it is associated.

Ranges from Tennessee, Missouri, and Kansas, south to Arkansas and Oklahoma.

The leaves generally average shorter and narrower than those of *I. melanopoda* f. *melanopoda*, and it appears of firmer texture than any of the other species in Missouri.

Order EQUISETALES

Fam. EQUISETACEAE (Horsetail Family)

4. *Equisetum* L. (Horsetail, Scouring Rush)

Plants of this genus contain a nerve poison which is known to be poisonous to grazing animals.

The stem is conspicuously jointed, with a sheath ending in a fringe of teeth at each joint, and in most species is hollow with a central cavity.

- a. Teeth not jointed with the sheath; fruiting stem of a different appearance from sterile stem, fleshy, varying from whitish to pinkish-brown or yellow-brown, appearing above the ground before the slender, green, branching, sterile stems which are only 1–5 mm. thick; cones long-peduncled . . . 1. *E. ARVENSE*
- a. Teeth definitely jointed; fruiting and sterile stems similar, green, stiff, mostly simple or only sparingly branched, usually 5–18 mm. thick; cones short-peduncled, the peduncle at most only slightly exceeding the subtending sheath b
- b. Stem smooth or nearly so, annual; cones rounded at tip 2. *E. KANSANUM*
- b. Stem roughened to some degree with silica deposit, perennial; cones apiculate c
- c. Sheaths at least the upper ones green or pale green 3. *E. LAEVIGATUM*
- c. All sheaths ashy-gray 4. *E. HYEMALE* var. *PSEUDOHYEMALE*

1. *Equisetum arvense* L.

Map 10

Field or Common Horsetail

A number of variations are known of which the following have been collected in Missouri:

- a. Branches of the whorls simple . . . 1a. *E. ARVENSE*
L. var. *ARVENSE* f. *ARVENSE*
- a. Branches of the whorls forking or compound . . . b
- b. Sterile stem depressed or nearly flat on the ground, the branches upright . . . 1b. *E. ARVENSE*
var. *ARVENSE* f. *DIFFUSUM* (A. A. Eat.) Clute
- b. Sterile stem erect or strongly ascending . . .
- IC. *E. ARVENSE* var. *ARVENSE*
f. *RAMULOSUM* (Rupr.) Klinge

Equisetum arvense f. *nemorosum* A. Br., recognized by Palmer and Steyermark in their 1932 list, is here considered synonymous with f. *ramulosum*.

The species and its varieties are commonly found along railroad embankments, roadsides, banks of streams, and low ground, and occur throughout the state. They occur nearly throughout the United States.

There are the two following different growth stages in this horsetail: (1) the fertile, mostly unbranched, fleshy and whitish to pink- or yellow-brown stems in early spring, followed by (2) green, more or less branched, vegetative or sterile stems arising from the same rootstock.

The fertile stems bear spores from April to May. The teeth of the lower sheaths of the fertile stems are dark brown or blackish, mostly separate from each other, and have long acuminate tips.

Most cases of *Equisetum* poisoning originate from

10 • *Equisetum arvense* var. *arvense* f. *arvense* (Common Horsetail)10 □ *Equisetum arvense* var. *arvense* f. *diffusum*
10 x *Equisetum arvense* var. *arvense* f. *ramulosum*11 *Equisetum kansanum* (Kansas Scouring Rush)12 *Equisetum laevigatum* (Smooth Scouring Rush)

E. arvense var. *arvense* or from one of its variations. Most trouble arises when hay including this horsetail is fed to horses. It is also known to be injurious to sheep.

2. *Equisetum kansanum* Schaffn.

Kansan Scouring Rush

Map 11

Equisetum laevigatum A. Br. [BB, in part]

Spores May–July.

Moist or dry banks, alluvial bottoms, and ditches. Known in Missouri only from St. Louis, Polk, and Greene counties.

Ranges from British Columbia, east to Michigan, south to Ohio, Texas, and California.

The status of the Kansan Horsetail as an acceptable species is not positive. Jones *et al.* (*Vascular Plants of Illinois*, pp. 12–13) cites evidence to show that no reliance can be placed on the characters of cone apex or habit used in distinguishing this species from *E. laevigatum*, and his opinion is shared with that of the eminent fern student, C. V. Morton (*Am. Fern Jour.* 43: 170. 1953). Other qualified students (Tryon *et al.*, *Ferns and Fern Allies of Wisconsin*, p. 119; Tryon, *Fern and Fern Allies of Minnesota*, p. 122; Billington, *Ferns of Michigan*, p. 83) maintain this as a distinct species. In Gleason's *New Illustrated Flora*, Morton (vol. 1, p. 14) places *E. kansanum* under *E. laevigatum* with the remarks, 'Plants with annual rather than evergreen stems have been distinguished as *E. kansanum* Schaffner.'

Only a few Missouri specimens have been identi-

fied as this species, which, at the present time, until other evidence is forthcoming, is being maintained as distinct from *E. laevigatum*. The ridges of the stem have poorly developed tubercles and are nearly smooth, as contrasted with the other species. The sheaths all have a black band at their summit but not at the base. It remains to be proved in Missouri whether the stems are definitely annual.

3. *Equisetum laevigatum* A. Br.

Smooth Scouring Rush

Map 12

Equisetum hyemale L. var. *intermedium* A. A. Eat.

Equisetum hyemale var. *intermedium* f. *proliferum* Haberer [G]

Spores March–July.

Moist ground along stream banks, alluvial bottoms, and open places. Scattered throughout the state.

Ranges from British Columbia, Michigan, and Massachusetts, south to California, Texas, Georgia, and West Virginia.

This species is intermediate between *E. hyemale* var. *pseudohyemale* (Farw.) Morton and *E. kansanum*. The lower sheaths are sometimes gray, appressed, and black-banded as in those of *E. hyemale* var. *pseudohyemale*, but the upper are green and flaring with little or no black band at base. In general, the stems are smoother than in *E. hyemale* var. *pseudohyemale*, and rougher than in *E. kansanum*.

A collection from Lawrence County (wet gravelly margins of spring brook, Big Spring, 5 mi. west northwest of Mt. Vernon, July 13, 1953, Palmer 56131-A)

Plate no. 2. 1. *Equisetum arvense*; a. Sheath from fertile stem, $\times \frac{1}{5}$; b. Sterile stem, $\times \frac{2}{5}$; c. Fertile stem, $\times \frac{2}{5}$. 2. *Equisetum laevigatum*; a. Sheath, $\times \frac{2}{5}$; b. Fertile stem, $\times \frac{2}{5}$. 3. *Equisetum hyemale*; a. Fertile stem, $\times \frac{2}{5}$; b. *Equisetum hyemale* var. *clatum*, Sheath, $\times \frac{2}{5}$; c. *Equisetum hyemale* var. *pseudohyemale*, Sheath, $\times \frac{2}{5}$. 4. *Botrychium dissectum* var. *dissectum*; a. Sterile blade, $\times \frac{2}{5}$; b. Fertile portion of frond, $\times \frac{2}{5}$. 5. *Botrychium dissectum* var. *obliquum*; a. Fertile portion of frond, $\times \frac{2}{5}$; b. Sterile blade, $\times \frac{2}{5}$. 6. *Botrychium virginianum*, $\times \frac{2}{5}$. 7. *Ophioglossum vulgatum* var. *pycnostichum*; a. Fertile portion of frond, $\times \frac{4}{5}$; b. Sterile blade, $\times \frac{2}{5}$. 8. *Ophioglossum Engelmanni*; a. Sterile blade, $\times \frac{2}{5}$; b. Fertile portion of frond, $\times \frac{2}{5}$. 9. *Azolla mexicana*, $\times 6$. 10. *Marsilea quadrifolia*, $\times \frac{2}{5}$; After Gleason, The New York Botanical Garden.

PLATE NO. 2

identified as *E. hyemale* var. *intermedium* f. *proliferum* is here placed under *E. laevigatum* and not segregated.

4. **Equisetum hyemale** L.

Winter Scouring Rush Map 13

Spores March–August.

Typical *E. hyemale* var. *hyemale* is an Eurasian plant, not represented in our flora. The Missouri varieties and forms may be distinguished as follows:

Teeth of most of sheaths quickly falling

4a. *E. HYEMALE* var. *PSEUDOHYEMALE*

Teeth of sheaths mostly persisting or falling off late in maturity. . . . 4b. *E. HYEMALE* var. *ELATUM*

4a. **Equisetum hyemale** var. **pseudohyemale**

(Farw.) Morton Map 13

Equisetum hyemale var. *affine* sensu A. A. Eaton [G], not *E. robustum* var. *affine* Engelm.

Equisetum variegatum [P & S], not Schleich.

The stems in this variety are generally more slender than in var. *elatum*, the diameter varying from 2–12 mm. in thickness.

Material from Jackson County, collected by Bush, misidentified previously as *E. variegatum*, is now identified as *E. hyemale* var. *affine* f. *polystachyum* Prager, which is considered in the present treatment as synonymous with *E. hyemale* var. *pseudohyemale*.

Ranges from Nova Scotia and Quebec to Ontario,

south to Georgia and Texas; also Colorado to Washington and British Columbia.

4b. **Equisetum hyemale** var. **elatum** (Engelm.)

Morton Map 13

Equisetum hyemale var. *robustum* (A. Br.) A. A. Eat. [G, P & S]

Equisetum robustum A. Br. [1st BB]

Equisetum prealtum Raf. [Pinkerton]

The stems in this variety are stouter than in var. *pseudohyemale*, the diameter averaging 6–18 mm. in thickness.

Ranges from Ontario to Idaho and Yukon, south to Florida, Texas, and California.

The above varieties of horsetail were at one time used extensively for scouring and polishing kitchen and other utensils and as a sandpaper material. In Holland a related variety is planted on the dikes to bind the soil. The young fruiting cones of this group of horsetail have been eaten, after being boiled and fried, but because of the nerve poison contained in this genus, it is recommended that the group be left untouched for gastronomic consideration.

The erect, mostly simple, dark evergreen stems occurring in dense colonies along stream banks and low alluvial ground is a familiar sight in many sections of the state where the varieties occur.

Order OPHIOGLOSSALES

Fam. OPHIOGLOSSACEAE (Adder's-tongue Family)

Green leaf-like portion (sterile blade) deeply split and lobed into three or more main divisions; fertile portion branched 5. **BOTRYCHIUM**

Green leaf-like portion (sterile blade) simple, entire, smooth-margined; fertile portion a simple, slender, tail-like spike 6. **OPHIOGLOSSUM**

5. **Botrychium** Sw. (Grape Fern)

All the Missouri species and varieties of *Botrychium* have a more or less triangular leaf-blade.

Leaf-like sterile blade dark green to bronze, overwintering, longstalked, the stalk arising less than half way up the main common stalk (stipe); margin of blade (under high magnification) whitish . . . 1. **B. DISSECTUM**

Leaf-like sterile blade pale or yellow-green, not overwintering, sessile or nearly so, attached about half to two-thirds way up the main common stalk (stipe); margin of blade not whitish . . . 2. **B. VIRGINIANUM**

1. **Botrychium dissectum** Spreng.

Grape Fern Map 14

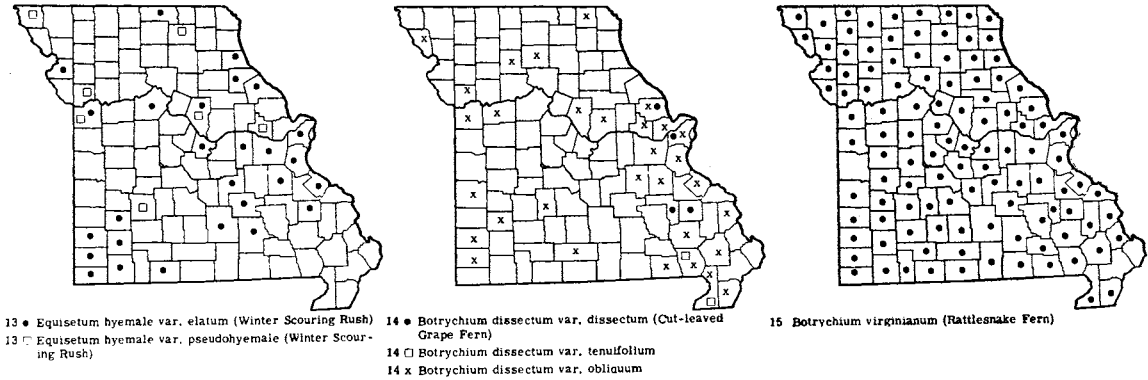

Three varieties may be distinguished in Missouri:

a. Leaf-like sterile blade finely cut into many very narrow, notched or emarginate, somewhat rectangular teeth or little lobes, appearing lace-like. 1a. **B. DISSECTUM** var. **DISSECTUM**

a. Leaf-like sterile blade coarsely divided into nearly entire or finely toothed segments b

b. Sterile blade firm or leathery, mostly tripinnate (the main and secondary segments again divided), the ultimate segments up to 100 or more, entire to minutely toothed, most of them rounded or broadened at the base . . . 1b. **B. DISSECTUM** var. **OBLIQUUM**

b. Sterile blade thin and membranaceous, pinnate (simply divided into the main segments) to bipinnate (main segments again divided into smaller segments), the ultimate

segments relatively few (5–35), mostly unlobed or only slightly lobed, mostly contracted to a somewhat narrowed base. . . .
1c. *B. DISSECTUM* var. *TENUIFOLIUM*

1a. ***Botrychium dissectum* Spreng. var. *dissectum***
Cut-leaved Grape Fern Map 14
Botrychium dissectum Spreng. [G, P & S]
Botrychium obliquum var. *dissectum* Prantl [Pinkerton]
Spores mature August–November.
This variety of the Grape Fern is rarely found in Missouri. Occurs in rich wooded ravines and narrow wooded valleys of the eastern section of the Ozarks north to Lincoln County.

Ranges from Nova Scotia to Minnesota, south to South Carolina, Tennessee, and Arkansas.
The sterile blade persists over winter, becoming bronze-russet or greenish and copper, disappearing in early summer when the new sterile and fertile blades appear.

1b. ***Botrychium dissectum* var. *obliquum***
(Muhl.) Clute Map 14
Botrychium dissectum f. *obliquum* (Muhl.) Fern. [G]
Botrychium obliquum Muhl. [Pinkerton]
Spores mature August–November.
This broad-leaved variety of the Cut-leaved Grape Fern is by far the commonest in Missouri, the new sterile blades appearing in fall and persisting until the following summer.

Occurs in rich wooded ravines and creek bottoms, generally in low ground, scattered over the state, most of the present known stations occurring in eastern Missouri.
Ranges from Nova Scotia and New Brunswick, west to Minnesota, and south to Georgia, Louisiana, and Oklahoma.

1c. ***Botrychium dissectum* var. *tenuifolium***
(Underw.) Farw. Map 14
Botrychium obliquum var. *tenuifolium* (Underw.) Gilbert [Pinkerton]
Spores mature September–November.
Known in Missouri from only two of the counties in the southeastern lowlands section, where it occurs in low wet woodland.
Ranges from Connecticut and Ohio, south to Florida, Missouri, and Texas.

2. ***Botrychium virginianum* (L.) Sw. var. *virginianum*** Rattlesnake Fern Map 15
Botrychium virginianum var. *intermedium* Butters [Pinkerton]
Spores mature May–July.
Occurs throughout Missouri in woodland in nearly every county.
Ranges from Labrador to British Columbia, south to Florida, Mexico, and California.
The thinner, paler green fronds do not persist over winter as in the preceding species.

6. ***Ophioglossum* L.** (Adder's-tongue)

Plants of wooded lowlands, valley, and creek bottoms; sterile blades blunt or rounded at tip; network of principal (towards middle of sterile blade) veins not enclosing any additional and smaller network 1. *O. VULGATUM*
Plants of limestone glades or outcroppings; sterile blades with a tiny projection at tip; network of principal veins (towards middle of sterile blade) enclosing an additional, smaller, secondary network 2. *O. ENGELMANNI*

16 • *Ophioglossum vulgatum* var. *pycnostichum* (Adder's-tongue)
16 □ *Ophioglossum vulgatum* var. *pseudopodium* (Adder's-tongue)

17 *Ophioglossum Engelmanni* (Adder's-tongue)

18 *Salvinia natans*

1. *Ophioglossum vulgatum* L. Map 16

Typical *Ophioglossum vulgatum* var. *vulgatum* is Eurasian. The two varieties found in Missouri may be keyed as follows:

Sterile blade ovate or ovate-lanceolate, mostly rounded at base, 1–4 cm. broad; sporangia transversely oblong . 1a. *O. VULGATUM* var. *PYCNOSTICHUM*

Sterile blade oblanceolate, obovate, or elliptic, mostly gradually tapering to the base, 0.7–3.2 cm. broad; sporangia suborbicular. . 1b. *O. VULGATUM*

var. *PSEUDOPODUM*

1a. *Ophioglossum vulgatum* var. *pycnostichum* Fern. Map 16

Ophioglossum vulgatum L. in part [BB]

Spores mature April–August.

This variety is known in Missouri at present from St. Charles (*Steyermark 81994*) and Lincoln counties, north of the Missouri River.

Ranges from South Carolina, Tennessee, and Missouri, north to New Jersey, Ohio, and Indiana.

The sterile blades average generally shorter (2.5–8.5 cm. long) than in the other variety. The common stalk of the plant usually has a persistent dark tubular sheath.

1b. *Ophioglossum vulgatum* var. *pseudopodium* (Blake) Farw. Map 16

Ophioglossum vulgatum L. in part [BB, P & S, Pinkerton]

Spores mature April–June.

This variety is found in Missouri mostly in the valley woodlands of Crowley Ridge and swampland of counties of southeastern Missouri, locally north in the Ozarks in Crawford County (*Steyermark 83927*). Small sterile plants of this variety are often found in such habitats appearing above the surface of the woodland floor in April.

2. *Ophioglossum Engelmanni* Prantl Map 17 Spores mature March–October.

This species is found as a characteristic plant of limestone glades and outcrops throughout the Ozarks north to Monroe and Ray counties; absent from the lowlands of southeastern Missouri.

Ranges from Florida to Arizona and Mexico, north to Virginia, Ohio, Indiana, Missouri, Kansas, and Oklahoma.

Wherever found, it is usually abundant. Frequently most of the individual plants found have sterile blades only. The species appears well adapted to withstand the alternating early wet spring followed by summer desiccation conditions prevalent on the limestone openings. After summer drouths the sterile blades usually wither and die, often reappearing in late summer or fall with new growth following rainy periods.

The isolated limestone glades where the species occurs at its northern limits in Monroe and Ray counties indicate areas which have not been subjected to Pleistocene glaciation.

Order FILICALES

Fam. SALVINIACEAE (Water Fern Family)

A family of floating plants in which the vascular tissue has become reduced. The small leaves, arranged on a more or less elongated axis, are roughened with papillae or tubercles.

Foliage leaves 1–1.5 cm. long, not lobed; stems simple 7. *SALVINIA*
Foliage leaves only 0.5 mm. long, minutely 2-lobed; stems pinnately branching 8. *AZOLLA*

19 *Azolla mexicana* (Mosquito Fern, Water Velvet)

20 *Marsilea quadrifolia*

21 *Marsilea mucronata*

7. *Salvinia* Adans. *Salvinia*

***Salvinia natans* (L.) All.** Map 18
Found in sloughs in the Bois Brule bottoms of the Mississippi River, Perry County, by *C. Demetrio* in 1886, presumably as an escape from cultivation, and not known elsewhere to occur in North America.

Native of Europe.
The Missouri locality has not been revisited for this plant, and it is not known whether the plants have persisted at this station.

8. *Azolla* Lam. Mosquito Fern, Water Velvet

***Azolla mexicana* Presl** Map 19
Azolla caroliniana [sensu G, P & S, Pinkerton], not Willd.
Spores mature summer and fall.
Floating on the surface of quiet waters or stranded along the muddy margins of ponds and ditches, scattered in counties of eastern and western Missouri bordering the Mississippi, Missouri, St. Francis, and other large rivers.
Ranges from Wisconsin, Minnesota, Illinois, and

Missouri, the western U.S., south into South America.
Plants usually appear as dense gray-green to purplish-red masses, and resemble small mosses or liverworts. Exposure to intense sunlight increases the purplish-rose coloring.
The upper leaf lobes measuring 0.7 mm. long or longer, and the greater spread of a single branched plant exceeding 1 cm. or more wide are characters used to distinguish this species from *A. caroliniana* Willd., which is not known in Missouri.

Fam. **MARSILEACEAE** (Pepperwort Family)

9. *Marsilea* L.

Aquatic plants, rooted in the mud, with clover-like leaves on long slender petioles.
Leaflets glabrous; fruiting structures (sporocarps) long-stalked, glabrous 1. *M. QUADRIFOLIA*
Leaflets sparsely hairy; fruiting structures (sporocarps) short-stalked, axillary at the base of the leaves, hairy 2. *M. MUCRONATA*
1. ***Marsilea quadrifolia* L.** Map 20
In the general range of the species, the spores mature from June–December. At the single Missouri station known, the spores are recorded as mature in October.
Known in Missouri only from muddy margins of Basswood Lakes, T53N, R34W, northeast ¼ sect.

27, Platte County, October 11, 1953, coll. *L. J. Gier* (see *Am. Fern Jour.* 45: 64–65. 1955). Dr. Gier believes that the plants have been introduced here from outside sources.
A European species, sometimes cultivated, and introduced from New England to Maryland west to Iowa and Missouri.

22 • *Osmunda regalis* var. *spectabilis* f. *spectabilis*
(Royal Fern)
22 □ *Osmunda regalis* var. *spectabilis* f. *anomala*

23 *Osmunda cinnamomea* (Cinnamon Fern)

24 *Osmunda Claytoniana* (Interrupted Fern)

2. **Marsilea mucronata** A. Br.

Map 21

M. vestita [of G, ed. 7, 1st BB], not Hook. & Grev.

The spores are recorded to mature in August and September. In Missouri they are known to fruit in September.

The single Missouri station is in Barton County,

southwestern Missouri (shallow water at the muddy grassy margins of a small pond, about $1\frac{1}{2}$ miles north of Milford, September 12, 1951, *E. J. Palmer 53101*).

Ranges from Minnesota and Saskatchewan, south to Florida, Texas, and Mexico.

Fam. **OSMUNDACEAE** (Royal Fern Family)

10. **Osmunda** L. (Royal Fern)

Large ferns with the sporangia borne naked on special completely fertile fronds or parts of fronds. The spores are green and contain chlorophyll.

- a. Leafy frond twice-pinnate, pinnules well separated; fertile pinnae, when present, at the upper part of the blade. *b*
- b. All the branches of the fertile portion spore-bearing 1. *O. REGALIS* var. *SPECTABILIS* f. *SPECTABILIS*
- b. Some of the branches of the fertile portion leaf-like 1. *O. REGALIS* var. *SPECTABILIS* f. *ANOMALA*
- a. Leafy frond once-pinnate, the pinnae deeply lobed (pinnatifid), the lobes close together; fertile fronds separate, or fertile pinnae borne between sterile ones *c*
- c. Tufts of woolly hair present at base of each sterile pinna; sterile pinnae loosely fringed with hairs on margins; lobes of pinnae acutish; fertile fronds separate from the sterile, densely woolly, cinnamon-colored fronds. 2. *O. CINNAMOMEA*
- c. Tufts of woolly hair mostly absent at base of each sterile pinna; sterile pinnae smooth; lobes of pinnae more rounded, obtusish; fertile pinnae borne between (above and below) sterile ones, green to black. 3. *O. CLAYTONIANA*

1. **Osmunda regalis** L. var. **spectabilis** (Willd.)

Gray f. **spectabilis** Royal Fern Map 22

Spores mature spring to late summer.

Wet ground along spring branches, or small creeks usually flowing through siliceous or granitic regions, the stems sometimes growing in water; also on moist

sandstone bluffs and ledges. Chiefly in the eastern Ozark region northeast to Pike County and locally northwest to Jackson County.

Ranges from Newfoundland to Saskatchewan, south to Florida, Texas, and tropical America.

Osmunda regalis var. *spectabilis* f. *anomala* (Farw.)

Plate no. 3. 1. *Osmunda regalis* var. *spectabilis*; a. Tip and middle of sterile frond, $\times \frac{2}{7}$; b. Portion of fruiting frond, $\times \frac{2}{7}$. 2. *Dennstaedtia punctilobula*; a. Tip of frond, $\times \frac{2}{7}$; b. Middle portion of frond, $\times \frac{2}{7}$; c. Base of frond, $\times \frac{2}{7}$; d. Pinnule with fruit dots, $\times \frac{6}{7}$. 3. *Osmunda Claytoniana*; a. Tip of frond, $\times \frac{2}{7}$; b. Middle portion of fruiting frond, $\times \frac{2}{7}$; c. Base of frond, $\times \frac{2}{7}$. 4. *Osmunda cinnamomea*; a. Fertile frond (portion), $\times \frac{2}{7}$; b. Tip of sterile frond, $\times \frac{2}{7}$; c. Middle portion of sterile frond, $\times \frac{2}{7}$; d. Base of sterile frond, $\times \frac{2}{7}$; e. Division of pinna showing venation, $\times \frac{6}{7}$.

PLATE NO. 3

Harris has been found along a spring branch in the Crowley Ridge section of Stoddard County (*Steyermark* 76774).

The Royal Fern is excellent for naturalizing around shores of streams and ponds.

2. ***Osmunda cinnamomea* L.**

Cinnamon Fern

Map 23

Spores mature May–June.

Boggy ground along small rivulets or spring branches in siliceous and granitic areas, or shaded sandstone or granitic ledges and bluffs, mostly in the eastern Ozark region north to Lincoln and Callaway counties, southeast on Crowley Ridge in Stoddard County, and locally west to Vernon County.

Ranges from Labrador to Minnesota, south to Florida, Texas, and tropical America.

In early spring the young unrolling sterile fronds ('fiddle-heads'), when not over 8 inches tall, are sometimes cooked as a vegetable, but do not compare very well in flavor with those of Ostrich Fern. The crisp, tender, central part of the crown, with its slightly

nutty flavor, is sometimes relished in a raw state by those acquainted with it.

The Cinnamon Fern does well in shady wild gardens, if provided with sufficient loose, acid humus and sandy, well-drained soil.

3. ***Osmunda Claytoniana* L.**

Interrupted Fern

Map 24

Spores mature May–July.

Rich wooded slopes of ravines, often on moist ledges of sandstone bluffs, occasionally in wet woods. Locally common north of the Missouri River northwest and west to Harrison, Daviess, and Jackson counties; absent from most of the Ozark region, where its occurrence is limited to a few of the easternmost counties.

Ranges from Newfoundland to Manitoba and Minnesota, south to Georgia and Arkansas.

This is the commonest of the larger ferns of the glaciated woodland ravines of northern Missouri. This fern does well in a shaded wild garden, if provided with loose rich humus and subneutral or somewhat acid soil.

Fam. **POLYPODIACEAE** (Fern Family, Polypody Family)

Herbaceous plants (in Missouri) with creeping rhizomes. The fruit dots or sori are clusters of sporangia, which are stalked and open transversely, and are massed in dots, lines, or variously shaped clusters on the back or margins of the frond or its divisions. A membrane (indusium) often covers the fruit dots, or it may be absent.

11. ***Dennstaedtia* Bernh.** Hay-scented Fern

These are pale green, delicate, finely hairy ferns with slender creeping rhizomes. The indusia are cup-shaped and open terminally, while the sorus is globular, marginal, and located at the tip of a free vein or fork of the upper margin of each lobe of the pinnules.

***Dennstaedtia punctilobula* (Michx.) Moore**

Hay-scented Fern

Map 25

Spores July–September.

One of the rarest ferns of Missouri, occurring only on shaded ledges of La Motte sandstone bluffs and ravines in Ste. Genevieve, St. Francois, and Madison counties of the southeastern Ozarks.

Ranges from Newfoundland and Nova Scotia to Michigan, south to Georgia, Illinois, and Arkansas.

Although a common fern in the New England states, where it frequently grows in old pastures, rocky sterile slopes, often exposed to the sun, in Missouri it is confined to deep shaded canyons, and undoubtedly represents a survivor from past migration during one of the interglacial stages of the Pleistocene period.

The bruised or crushed fronds give off a sweet odor, resembling newly mown hay.

12. ***Pteridium* Gled.** Bracken

Large coarse ferns with long, creeping, hairy, underground rhizomes, stiff, erect, solitary stipes and broad, generally triangular-shaped, mostly tripinnately compound, nearly leathery fronds with mostly opposite pinnae and relatively large alternate pinnules. The sori are arranged more or less continuously along the margins of the frond, with the sporangia located under the recurved border of the leaf segment (outer false indusium) and the minute true inner indusium (membranous or of hairs).

***Pteridium aquilinum* (L.) Kuhn**
Bracken

Map 26

Only the following two varieties of the Bracken Fern are known in Missouri, but Tryon (Rh. 43: 12-15, 1941), in his revision of the genus, accounts for ten additional varieties, distributed over most of the hemispheres. Intergradation and intermediates between the following two varieties occur.

The longest entire leaf-segment or part of a leaf-segment about 4 times as long as wide; terminal leaf-segments 5-8 mm. wide; margins of the ultimate leaf-segments somewhat pubescent.

a. *P. AQUILINUM* var. *LATIUSCULUM*

The longest entire leaf-segment or part of leaf-segment 6-9 or more times as long as wide; terminal leaf-segments mostly 2-4.5 mm. wide; margins of the ultimate leaf-segments mostly glabrous or nearly so

b. *P. AQUILINUM*
var. *PSEUDOCAUDATUM*

a. ***Pteridium aquilinum* (L.) Kuhn var. *latiusculum*** (Desv.) Underw.

Map 26

Pteridium latiusculum [P & S, Pinkerton]

Spores mature July-September.

Rocky or dry open woods, in acid soil, mostly confined to Ozark region in southern and east-central Missouri west to Vernon and Camden counties, locally north of the Missouri River in Boone, Monroe, and Sullivan counties.

Ranges from Newfoundland, Ontario, and South Dakota, and Wyoming, south to North Carolina, Mississippi, Missouri, Oklahoma, and locally in Mexico.

The fresh and dried fronds of this and the other variety of Bracken Fern in hay are poisonous to stock. Pigs, however, are not affected by eating the fresh rhizomes. The young leafy fronds, when thoroughly cooked, may be eaten like asparagus.

b. ***Pteridium aquilinum* var. *pseudocaudatum***

(Clute) Heller

Map 26

Pteridium latiusculum var. *pseudocaudatum* [P & S, Pinkerton]

Spores mature July-September.

Rocky or dry open woods, in acid soil in the Ozark section of the state, north to Jasper, Dallas, Franklin, and Lincoln counties.

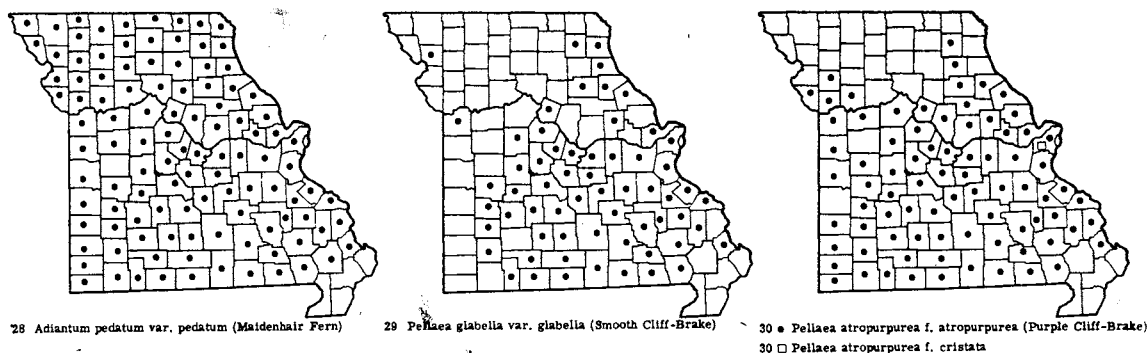

This is a more southern variety, distributed from Massachusetts, Indiana, Missouri, and Oklahoma, south to Florida and Texas.

Neither variety of Bracken in Missouri becomes the dominant and weedy plant that can form dense thickets and take over extensive patches of terrain, such as in the more northern and eastern states, especially in burnt-over sections of those areas. Some varieties of Bracken attain heights of 4 meters.

The fresh young stipes are, on occasion, tasted or chewed for their mucilaginous juice. By removing the woolly hairs from the young stipes, it is possible to use the uncurling young fronds as a cooked vegetable in the spring as an asparagus substitute. The plants in various countries have been employed in a number of ways. In some countries the fronds are used as thatching, packing material, and for glass making. The green fronds, when burned, produce potash.

13. ***Adiantum* L.** Maidenhair

Ferns with forking, delicate, finely cut fronds on a brown- or reddish-black stipe naked and scaleless above the base from a slender, creeping rhizome. The indusium is lacking, but the margin of some pinnules is folded

down to form a false indusium over the marginal sporangia. (The name *adiantum* is derived from a word meaning unwetted, because the leaf-blade sheds rain.)

Leaf-blade longer than broad; main rachis with alternate branching, not forked at summit; fronds hanging from wet, usually limestone bluffs, rarely on sandstone 1. *A. CAPILLUS-VENERIS*

Leaf-blade broader than long; main stipe palmately forking at summit, then curving into opposite directions; stipes upright with horizontal foliage; growing usually on the ground, sometimes on moist bluffs 2. *A. PEDATUM*

1. *Adiantum Capillus-veneris* L.

Venus'-hair Fern

Map 27

Spores mature June–August.

The usual habitat is mossy, moisture-soaked cracks of overhanging limestone bluffs. Venus'-hair Fern is confined to the Ozark section of the state; it is common in the counties drained by the Current, Eleven Points, White, North Fork, Piney, Niangua, and Gasconade rivers, north into Dallas and Phelps counties, and locally northeast to Jefferson County. The collection originally cited by Palmer & Steyermark (Am. Fern. Jour. 22: 111. 1932) from 'woods' in Saline County is based upon erroneous data and should be eliminated.

Ranges from tropical America, north in the United States to Virginia, Kentucky, Missouri, South Dakota, Colorado, Utah, and California.

The drooping habit of the fronds is characteristic.

In favorable habitats it is quite abundant, occurring in dense tiers or patches in the horizontal or

vertical cracks of the strata. In dry years the fern may withstand considerable desiccation. Numerous buff-colored dried fronds may be found at the base of the clumps. Usually, however, sufficient moisture is available, and, in seasons of abundant water, the roots may be subjected to almost constantly running or dripping water.

2. *Adiantum pedatum* L. var. *pedatum*

Maidenhair Fern

Map 28

Spores mature June–August.

A common fern of rich wooded slopes, ravine bottoms, and rarely occurring on moist rocky ledges and bluffs. It occurs throughout the state, and is absent only from the extreme southeastern lowland counties.

Ranges from Quebec, Ontario, and Minnesota, south to Georgia, Louisiana, and Oklahoma.

The Maidenhair Fern responds favorably to transplanting to shaded wild gardens, but needs a light humus soil.

Plate no. 4. 1. *Pteridium aquilinum* var. *latiusculum*, $\times \frac{2}{7}$; a. Lower surface of pinnae, $\times \frac{2}{7}$; b. Margin of fertile segment rolled back to show indusium, $\times \frac{4}{7}$; After Gleason, The New York Botanical Garden. 2. *Adiantum Capillus-veneris*, $\times \frac{2}{7}$. 3. *Adiantum pedatum*, $\times \frac{2}{7}$; a. Pinnule, showing marginal sporangia, $\times \frac{6}{7}$. 4. *Pellaea atropurpurea*, $\times \frac{2}{7}$; a. Lower surface of fertile pinnule, showing continuous indusium, $\times \frac{1^3}{7}$; After Gleason, The New York Botanical Garden. 5. *Notholaena dealbata*, $\times \frac{2}{7}$; a. Pinnule, lower surface, with sporangia, $\times \frac{2^6}{7}$; After Gleason, The New York Botanical Garden. 8. *Cheilanthes tomentosa*, $\times \frac{2}{7}$; a. Pinna with pinnules, lower surface, $\times \frac{2^6}{7}$; After Gleason, The New York Botanical Garden.

PLATE NO. 4

14. **Pellaea** Link Cliff-Brake

Rock ferns with evergreen grayish-blue-green, or gray-green blades.

Main stems (stipe) and rachis (slender axis to which leaf-segments are attached) without hairs or very sparsely hairy, dark reddish-brown and shining; blades bluish-green, their lowest branches at most short-stalked or nearly sessile; lowest pinnae less than twice as long as the upper pinnae . . . 1. *P. GLABELLA*

Main stems (stipe) and rachis scurfy with hairs, dark purple-brown or blackish-purple to gray, dull; blades dull green, at least their lowest branches showing definite stalks; lowest pinnae usually 2 or more times as long as the upper pinnae 2. *P. ATROPURPUREA*

1. **Pellaea glabella** Mett. ex Kuhn var. **glabella** Map 29
Smooth Cliff-Brake
Pellaea atropurpurea var. *Bushii* Mack. [BB]
Pellaea atropurpurea var. *minima* Eggert ex Farw.
Spores mature April–October.

Occurs usually on limestone cliffs or boulders throughout the Ozark region northeast to Lewis and Knox counties and locally in Andrew County, northwestern Missouri.

Ranges from Ontario to Texas, east to Vermont, Virginia, and Tennessee.

2. **Pellaea atropurpurea** (L.) Link Map 30
Purple Cliff-Brake

Main leaf-segments (pinnae) simple or pinnately divided; common type . . . 2a. *P. ATROPURPUREA*
f. *ATROPURPUREA*

Main leaf-segments (pinnae) forked, crowded toward tip of frond; rare . . . 2b. *P. ATROPURPUREA*
f. *CRISTATA*

- 2a. **Pellaea atropurpurea** f. **atropurpurea** Map 30
Clute

Spores mature June–September.

Occurs throughout the Ozark region northeast in the state to Knox County and northwest to Platte County. Ranges from British Columbia, Saskatchewan, and Vermont, south to Florida, Texas, Mexico, and Guatemala.

- 2b. **Pellaea atropurpurea** f. **cristata** (Trel.) Map 30
Clute
Pellaea atropurpurea var. *cristata* Trel. [P & S, Pinkerton]

Known in the United States only from the original Missouri station, collected in 1899 on limestone rocks, Eureka, St. Louis County, by Gustav Pauls.

This form is considered synonymous with *P. atropurpurea* by Dr. Alice F. Tryon in her recent revision of the genus *Pellaea*, section *Pellaea* (Ann. Mo. Bot. Gard. 44: 144. 1957), but it should merit the same recognition acknowledged for similar variations of sporadic appearance among other ferns.

15. **Notholaena** R. Br. Cloak-Fern

Tufted rock ferns with finely divided small blades and wiry blackish stipes. The mostly solitary sporangia are borne in sori near the scarcely recurved margins of the pinnules, and an indusium is absent.

- Notholaena dealbata** (Pursh) Kunze Map 31
Pellaea dealbata (Pursh) Prantl [BB]
Spores mature June–September.

On dry limestone or dolomite cliffs, ledges, or boulders, chiefly in western Missouri, locally east to Howard and St. Louis counties.

Ranges from Texas and Arkansas, north to Colorado, Nebraska, and east-central Missouri.

Morton has brought evidence (Am. Fern Jour. 40: 249. 1950) to show that this fern may better be included in the genus *Pellaea* as *Pellaea dealbata* (Pursh) Kunze.

16. **Cheilanthes** Sw. Lip-Fern

Tufted rock ferns with dark wiry stipes and finely divided blades. An indusium-like flap (false indusium) is developed as the folded or reflexed margins of the leaf-lobes covering the separate or nearly approximate, small rounded sori.

31 *Notholaena dealbata* (Cloak Fern)32 *Cheilanthes alabamensis* (Lip Fern)33 *Cheilanthes lanosa* (Hairy Lip Fern)

- a. Blades hairless (glabrous) or nearly so on lower surface 1. *C. ALABAMENSIS*
 a. Blades obviously hairy (pubescent) on the lower surface b
 b. Mature stipes becoming nearly glabrous, or at most with scattered hairs; fronds mostly 4–14 cm. long, the blade mostly 2–6 cm. long; main pinnae rather dense and crowded; plants of dry limestone bluffs 4. *C. FEEI*
 b. Mature stipes densely woolly or with obvious spreading hairs; fronds mainly 7–50 cm. long, the blade mainly 6–25 cm. long; main pinnae well separated from each other; plants of sandstone, chert, or granite, rarely limestone c
 c. Leaf-blades twice pinnate, mostly 6–15 cm. long, the pubescence on lower surface of spreading hairs; fronds averaging 12–23 cm. long; rhizome elongated, creeping; plants of sandstone, chert, or granite rocks 2. *C. LANOSA*
 c. Leaf-blades three times pinnate, mostly 12–25 cm. long, very densely woolly on lower surface; fronds averaging 25–40 cm. long; rhizome short, condensed; rare limestone plant . . . 3. *C. TOMENTOSA*

1. ***Cheilanthes alabamensis*** (Buckl.) Kunze

Map 32

Spores mature August–October.

On dry limestone and dolomitic bluffs and mossy boulders in the southwestern Ozark section east to Ozark County.

Ranges from Georgia, north to Virginia, Tennessee, Missouri, and Oklahoma, and west to Arizona, Texas, and Mexico.

2. ***Cheilanthes lanosa*** (Michx.) D. C. Eaton

Hairy Lip-Fern

Map 33

Cheilanthes vestita (Spreng.) Sw. [G]

Spores mature June–September.

On dry, often mossy, sandstone, chert, or granitic outcrops or ledges of bluffs, throughout the Ozark region north to Barton, Henry, Benton, Cole, Callaway, and Pike counties.

Ranges from Georgia and Texas, north to West Virginia, Pennsylvania, Indiana, Illinois, Missouri, and Kansas, with local stations northward in Wisconsin, New York, and Connecticut.

The leaf-blades are of a dull rusty green color. This fern can withstand long periods of drouth, during which time the fronds curl up and become brittle, but quickly revive after rains. It can be transplanted to sandy or sterile soils and rock ledges.

3. ***Cheilanthes tomentosa*** Link

Woolly Lip-Fern

Map 34

Cheilanthes lanosa [G], not (Michx.) Eaton

Spores mature June–September.

The only known station for this fern was found on August 22, 1935, (*Steyermark 19530*), one-half way up exposed crevices of limestone bluffs on an escarpment at the junction of Indian Creek and White River, Stone County, southwestern Missouri. Unfortunately, the area has now been destroyed by the impounded waters of Table Rock Dam.

Ranges from Virginia and Kentucky, south and west to Georgia, Missouri, Arkansas, Texas, and Mexico.

4. ***Cheilanthes Feei*** Moore

Fée's Lip-Fern, Slender Lip-Fern

Map 35

Spores mature June–October.

This fern has a gray-green color on the upper surface, in contrast to the other common species, *C. lanosa*, which has a dull rusty-green color with the pinnae more separated.

In crevices of west- or south-facing dry limestone and dolomitic bluffs and boulders throughout the Ozark region where it occurs west to Jasper, Cedar, Henry, Benton, and Howard counties, thence north-east to Lewis County.

34 *Cheilanthes tomentosa* (Woolly Lip Fern)35 *Cheilanthes Feei* (Fee's Lip Fern)36 *Polypodium polypodioides* var. *Michauxianum*
(Gray Polypody)

Ranges from Illinois and Wisconsin to British Columbia, south to Missouri, Arkansas, Texas, Arizona, and California.

During periods of extensive drouth, this fern may become as dried and shriveled-looking as some

lichens, but the blades quickly become soft again after rains.

This species, so far as my experience goes, cannot be transplanted unless the original rock is taken without disturbing the fern.

17. *Polypodium* L. Polypody

Ferns growing upon either rocks or trees, with creeping superficial rhizomes; pinnately cut blades (not divided to the midrib), and round sori without an indusium.

Stipe and lower side of leaf-blade densely gray or gray-brown scaly; leaf-segments entire (without teeth) 1. *P. POLYPODIODES* var. *MICHAUXIANUM*

Stipe and lower side of leaf-blade green; leaf-segments minutely toothed 2. *P. VULGARE* var. *VIRGINIANUM*

1. *Polypodium polypodioides* (L.) Watt var.

***Michauxianum* Weath.**

Resurrection Fern, Gray Polypody Map 36
Spores mature June–September.

In the lowland swamp counties of southeastern Missouri, this species is found always on the trunks and limbs of forest trees, and likewise grows epiphytically on trees along courses of streams in southern Missouri. Northward in the Ozark region it occurs usually on mossy sandstone or chert ledges or boulders of wooded bluffs. In Missouri it is confined to the Ozark section of the state, ranging north to Newton, Laclede, Phelps, Franklin, and St. Louis counties, and in Warren County in an unglaciated section of the Ozarks just north of the Missouri River.

Ranges from Guatemala, Texas, and Florida, north to Oklahoma, Iowa, Missouri, southern Illinois, Kentucky, Virginia, and Delaware.

During periods of drouth, this fern can shrivel and curl the blades, appear to be dead, but quickly

revives following rains. It transplants easily, when given mossy rocks or bark, but dies out in extreme cold spells during winters of the northern United States.

2. *Polypodium vulgare* L. var. ***virginianum* (L.)**

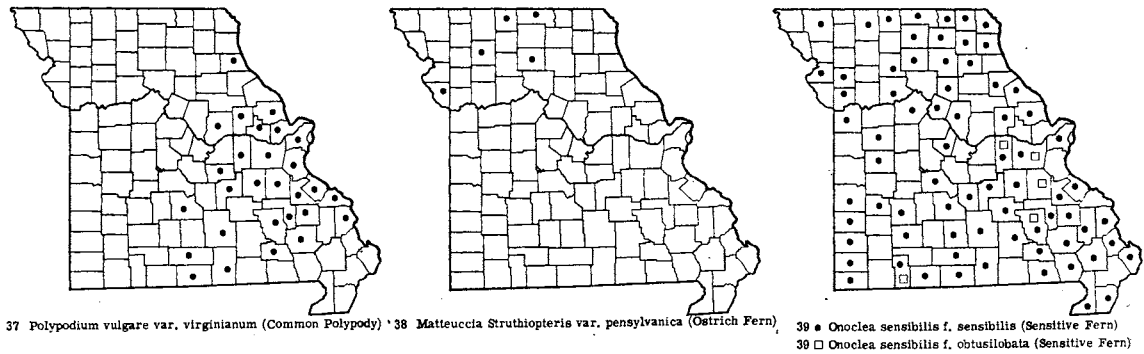

Eaton Common Polypody Map 37

Polypodium virginianum L. [G]

Spores mature July–August.

On mossy, often dry, ledges of sandstone, chert, granite, or porphyritic trachyte bluffs and boulders, usually exposed to the north or east, generally following streams or branches heading up into ravines throughout the eastern part of the Ozark section, west to Callaway, Maries, Laclede, Douglas, and Ozark counties and locally north in Marion County; absent from the swampland of southeastern Missouri.

Ranges from Newfoundland to Alaska, south to Georgia, Alabama, Tennessee, and Arkansas.

18. *Matteuccia* Todaro Ostrich Fern

Large terrestrial ferns, the fertile and sterile fronds unlike. The sterile fronds are once-pinnate with pinnatifid pinnae, and surround in vase-like arrangement the shorter, simply pinnate, and plume-like fertile fronds.

Matteuccia Struthiopteris (L.) Todaro var.
pensylvanica (Willd.) Morton Ostrich Fern
Map 38

Pteritis pensylvanica (Willd.) Fern [G]
Pteritis nodulosa (Michx.) Nieuwl. [P & S, Pinkerton]
Spores mature July–October.

In Missouri a very rare fern, found in rich alluvial woods and along banks of streams and wet ground in scattered sections of northern and west-central Missouri, where it is known from Putnam, Mercer, Linn, Daviess, and Platte counties.

Ranges from Newfoundland to Alaska, south to

Virginia, Ohio, Missouri, and British Columbia.

This is one of the most beautiful and graceful native ferns, the blades of the larger sterile fronds arising in a vase-like form, abruptly narrowed at each end and widened towards the middle.

Since it is a rare fern in Missouri, it should be rigidly protected. In the northern and northeastern part of its range, where the fern is more common, the tender young leaves are gathered before they have uncoiled and cooked as a substitute for asparagus. Served with melted butter, salt and pepper, they furnish a tasty morsel.

19. *Onoclea* L. Sensitive Fern

Terrestrial ferns with creeping, forking rhizomes, solitary long-stalked sterile fronds with pale green deeply pinnatifid leaf-blades, and separate, stiffly erect, twice pinnate fertile fronds. The ultimate divisions (pinnules) of the fertile fronds are reduced to ball-like segments filled with sporangia.

Onoclea sensibilis L. Sensitive Fern Map 39

The following variations occur in Missouri:

Spore-bearing (fertile) blade completely uniform;
leaf-blade completely uniform. . . . a. *ONOCLEA*
SENSIBILIS f. SENSIBILIS

Spore-bearing (fertile) blade not uniform (some of thesegments leaf-like), or, if uniform, then some of the segments of the leaf-like (sterile) blade with some spore-bearing segments . . . b. *ONOCLEA*
SENSIBILIS f. *OBTUSILOBATA*

a. ***Onoclea sensibilis* L. f. *sensibilis*** Map 39
Spores mature June–November.

Occurs in wet woods and thickets, and along streams and spring branches throughout the state.

Ranges from Newfoundland, Saskatchewan, Minnesota, and South Dakota, south to Florida and Texas.

With the coming of the first frosts and cold spells, the sterile leaf-blades wither and die, hence the common name for this fern. Horses fed on hay containing this fern in combination with bracken and horsetail appear to be adversely affected thereby.

b. ***Onoclea sensibilis* f. *obtusilobata*** (Schkuhr)
Gilbert Map 39

This form, which combines characters of both fertile and sterile fronds, and in addition, has partially netted venation of the leaf-blade, has been collected from only a few counties in the state, and is scattered throughout the range of f. *sensibilis*.

40 *Woodwardia areolata* (Netted Chain Fern)41 *Asplenium pinnatifidum* (Pinnatifid Spleenwort)42 *Asplenium Ruta-muraria* var. *cryptolepis* (Wall-Rue Spleenwort)

20. *Woodwardia* Smith Chain Fern

Terrestrial ferns of wet ground with creeping rhizomes and fertile and sterile fronds on separate blades. The narrow linear fruit dots (sori) are arranged in chain-like rows parallel to the midrib of the narrow leaf-divisions of the fertile blade, the narrow indusium being attached on one side.

Woodwardia areolata (L.) Moore

Netted Chain Fern

Map 40

Spores mature July–October.

One of the rarest ferns of Missouri. Swampy or wet ground in wooded areas. Of the four stations known, all in the southern part of the state, two were discovered in southwestern Missouri by E. J. Palmer (wet springy ground below sandstone ledge, along Horse Creek, northeast of Milford, Barton County, *Palmer 53205*; Lawrence County), and two in south-

eastern Missouri (*Eby*, Poplar Bluff, Butler County and *Steyermark 80393*, along sandy banks of a spring branch in sand hills of Crowley Ridge, T25N, R10E, northeast $\frac{1}{4}$ sect, 1, $3\frac{1}{2}$ – $3\frac{3}{4}$ mi. [by air] south-east of Bloomfield in Stoddard County). The latter two stations are at the junction of Crowley Ridge and the swampy lowlands.

Ranges from Florida and Texas, north to Nova Scotia, Tennessee, Missouri, and Oklahoma, and locally in Michigan.

21. *Asplenium* L. Spleenwort

Small, evergreen, frequently rock-inhabiting ferns with mostly wiry, green to black stipes bearing several to numerous pairs of toothed or lobed segments or pinnae. The sori are usually longer than broad with a narrow indusium attached at one side.

a. Leaf-stalk (stipe) as well as main axis (rachis) of leaf-blade completely green; leaf-blade twice pinnate, the smaller divisions cut all the way to the midrib of the main pinnae, with no green connecting tissue at base; the main pinnae alternately arranged on the rachis, the lower divisions all stalked (petiolate) 2. *A. RUTA-MURARIA* var. *CRYPTOLEPIS*

a. Leaf-stalk (stipe) at least brown, purple-brown, or black at base or completely dark, but not completely green; main axis (rachis) of leaf-blade green, partly brown, purple-brown, black or wholly brown, purple-brown, or black from base to tip; leaf-blade simply or once-pinnate, or partly or

Plate no. 5. 1. *Cheilanthes Feei*, $\times \frac{2}{7}$; a. Portion of pinna, lower surface, with sporangia, $\times 2$; After Gleason, The New York Botanical Garden. 2. *Polypodium polypodioides* var. *Michauxianum*, $\times \frac{2}{7}$; a. Lower portion of fertile pinna, $\times \frac{6}{7}$; After Britton and Brown, The New York Botanical Garden. 3. *Polypodium vulgare* var. *virginianum*, $\times \frac{2}{7}$; a. Lower portion of fertile pinna, $\times \frac{6}{7}$; After Britton and Brown, The New York Botanical Garden. 4. *Matteuccia Struthiopteris* var. *pennsylvanica*; a. Tip of sterile frond, $\times \frac{2}{7}$; b. Middle portion of sterile frond, $\times \frac{2}{7}$; c. Base of sterile frond, $\times \frac{2}{7}$; d. Fertile frond, $\times \frac{2}{7}$. 5. *Onoclea sensibilis*, $\times \frac{2}{7}$; a. Fertile frond, $\times \frac{2}{7}$; b. Cluster of sporangia, $\times 1\frac{5}{7}$; c. Sporangium opening and shedding spores, $\times 2\frac{6}{7}$. 6. *Woodwardia areolata*, $\times \frac{2}{7}$; a. Lower portion of fertile pinna, $\times \frac{2}{7}$; After Britton and Brown, The New York Botanical Garden. 7. *Asplenium pinnatifidum*, $\times \frac{2}{7}$; After Gleason, The New York Botanical Garden. 8. *Asplenium Ruta-muraria* var. *cryptolepis*, $\times \frac{4}{7}$; After Gleason, The New York Botanical Garden. 9. *Asplenium Trichomanes*, $\times \frac{2}{7}$; a. Fertile pinna, lower portion, $\times 1\frac{5}{7}$; After Gleason, The New York Botanical Garden. 10. *Asplenium resiliens*, $\times \frac{2}{7}$; a. Fertile pinna, lower portion, $\times 2$; After Gleason, The New York Botanical Garden.

PLATE NO. 5

- deeply lobed, sometimes the tip becoming prolonged and tail-like; the main pinnae opposite or alternate, without stalks (sessile) *b*
- b. Stipe dark brown only near base, otherwise green; rachis green from base to tip . . . 1. *A. PINNATIFIDUM*
- b. Stipe completely dark brown or black; rachis either completely dark brown or black or green in upper half or three-fourths *c*
- c. Stipe and rachis completely dark brown, purple-brown to black from base to tip *d*
- d. Leaf-divisions (pinnae) alternate 5. *A. PLATYNEURON*
- d. Leaf-divisions opposite *e*
- e. Stipe and rachis purple-brown; leaf-divisions without a small ear-like lobe (auricle) at base, broadest above the base; growing on sandstone, chert, or granitic rocks . 3. *A. TRICHOMANES*
- e. Stipe and rachis blackish; leaf-divisions with a small ear-like lobe (auricle) at base, broadest at the base; growing on limestone 4. *A. RESILIENS*
- c. Stipe dark brown; lower part of the rachis brown, the remainder green *f*
- f. Stipes and lower part of rachis purple-brown; main pinnae with usually somewhat wavy margins, but without fine short teeth or pointed lobes; upper part of leaf-blade conspicuously long-tapering, tail-like, and usually without prominent lobes; growing usually on limestone rocks 6. *A. × ASPLENIODES*
- f. Stipes and lower part of rachis brown; main pinnae usually with small pointed or rounded teeth on margins, not wavy-margined; upper part of leaf-blade narrowed, but not prolonged and tail-like, usually with lobes and teeth; growing usually on sandstone, chert, or granitic rocks *g*
- g. Rachis dark brown for $\frac{1}{4}$ its length, green for remaining $\frac{3}{4}$; most of pinnae deeply lobed or cut; rachis mostly not winged 7. *A. BRADLEYI*
- g. Rachis barely brown at base, green most of its length; most of pinnae only slightly toothed, not deeply lobed; rachis slightly winged 8. *A. × GRAVESII*

1. ***Asplenium pinnatifidum* Nutt.** Lobed

Spleenwort, Pinnatifid Spleenwort Map 41
Spores mature July–October.

This fern seeks sheltered crevices of noncalcareous bluffs along narrow ravines and canyons at the headwaters of small creeks on shaded sandstone and granitic ledges of bluffs or boulders, in the eastern section of the Ozarks west to Maries County.

Ranges from Georgia and Oklahoma, north to Pennsylvania, Indiana, and Missouri.

This fern has sometimes been confused with the hybrid Scott's or Walking Spleenwort (*A. × ebenoides*), but may be distinguishable by the rachis, being green throughout its length, by the stipe dark only near the base, and by the habitat on noncalcareous sandstone or granitic rocks.

Dr. Wagner had produced evidence to show that this fern is a fertile tetraploid of hybrid origin between the Walking Fern (*Camptosorus rhizophyllus*) and *Asplenium montanum*. The latter species does not occur in Missouri.

2. ***Asplenium Ruta-muraria* L. var. *cryptolepis***

(Fern.) Wherry Wall-Rue Spleenwort Map 42
Asplenium cryptolepis Fern. [G, P & S, Pinkerton]
Spores mature May–September.

Shaded, mossy crevices of limestone in the upper portion of escarpments or bluffs, generally on exposures facing east or north. Although not abundant, this tiny fern occurs fairly frequently in the eastern

Ozark section west to Laclede, Texas, Ozark, and Stone counties and northeast to Jefferson County.

Ranges from Vermont, Ontario, and Michigan, south to Alabama, Illinois, Missouri, and Arkansas.

3. ***Asplenium Trichomanes* L.**

Maidenhair Spleenwort Map 43
Spores mature July–September.

Usually in shaded moist crevices of overhanging ledges of sandstone, chert, or granitic bluffs or boulders, rarely on calcareous rocks. Scattered throughout the southern and eastern sections of the Ozarks, north to Cedar, Polk, Phelps, Franklin, and St. Louis counties. North of the Missouri River it is known from isolated St. Peter sandstone bluffs in Lincoln County in an area which has apparently escaped glaciation.

Ranges from Nova Scotia and Manitoba to Wisconsin and North Dakota, south to Georgia, Alabama, and Texas; also found in the western states north to Alaska.

This very dainty fern may be grown if given sufficient moisture and shelter from drying winds. A porous usually noncalcareous rock seems preferred as a growing medium.

4. ***Asplenium resiliens* Kunze** Little Ebony Spleenwort, Blackstem Spleenwort Map 44
Spores mature May–October.

Shaded crevices of limestone and dolomitic bluffs and boulders throughout the Ozark region, following

43 *Asplenium Trichomanes* (Maidenhair Spleenwort)44 *Asplenium resiliens* (Little Ebony Spleenwort)45 • *Asplenium platyneuron* var. *platyneuron* f. *platyneuron* (Ebony Spleenwort)45 □ *Asplenium platyneuron* var. *platyneuron* f. *serratum*

courses of small and large streams, north to Jasper, Henry, Benton, Camden, Phelps, Washington, and St. Louis counties, locally northwestward in Jackson County.

Ranges from Florida, Mexico, and Arizona north to Pennsylvania, Ohio, Kentucky, southern Illinois, Missouri, Kansas, and Oklahoma; also in the West Indies and western South America.

The black stipe and rachis quickly distinguish this fern from *A. platyneuron*.

5. ***Asplenium platyneuron* (L.) Oakes**

Ebony Spleenwort

Map 45

The following variations occur in Missouri:

Main leaf-divisions (pinnae) narrowly ovate to oblong-lanceolate with minutely toothed margins; tip of the pinna rounded or bluntly pointed.

5a. ***A. PLATYNEURON* var. *PLATYNEURON* f. *PLATYNEURON***

Main leaf-divisions (pinnae) linear-lanceolate, with mostly sharply toothed margins; tip of the pinna tapering to an acute tip. 5b. ***A. PLATYNEURON* var. *PLATYNEURON* f. *SERRATUM***

5a. ***Asplenium platyneuron* var. *platyneuron***

f. *platyneuron*

Map 45

Spores mature May–September.

Open wooded slopes, mossy banks, and rocky wooded ledges of all kinds of rocks, but more frequently in sandstone, chert, and granitic areas. Found commonly throughout southern and central Missouri, becoming less common in the northern section of the state.

Ranges from Florida and Texas, north to Maine, Quebec, Ontario, Wisconsin, Iowa, and Colorado.

5b. ***Asplenium platyneuron* var. *platyneuron***

f. *serratum* (E. S. Miller) Hoffm.

Map 45

This form is known from several counties within the general range of var. *platyneuron*.

6. ***Asplenium* × *ebenoides* R. R. Scott**

Walking Spleenwort

× *Asplenosorus ebenoides* (R. R. Scott)

Wherry [G, BB]

Map 46

Spores mature July–September.

The fern is of only rare occurrence in Missouri. The known localities in the state are from shaded limestone ledges and boulders, often at the foot of limestone bluffs along creeks, in the eastern half of the Ozarks west to Phelps and Ozark counties and northeast to St. Louis County.

Ranges from Vermont to Alabama, west to Missouri.

It has been shown that this fern is of hybrid origin between Ebony Spleenwort (*Asplenium platyneuron* var. *platyneuron*) and Walking Fern (*Camptosorus rhizophyllus*). It may also be associated with Little Ebony Spleenwort (*Asplenium resiliens*), as noted for the collection from Washington County by *Albert Chandler 401230* in the Mo. Bot. Gard. Herb.

The genus *Asplenosorus* is considered as invalid by Morton, since it was published without a Latin description. *Asplenium* × *ebenoides* and other hybrids that might be placed in *Asplenosorus* are referred by Morton to *Asplenium*.

7. ***Asplenium Bradleyi* D. C. Eat.**

Bradley's Spleenwort

Map 47

Spores mature June–September.

Dry sheltered crevices of sandstone, chert, or granitic cliffs, scattered throughout the Ozark region west to Vernon County, north to St. Clair, Maries, Montgomery, and Franklin counties. The Montgomery County station (*Steyermark 86127*) is the only record north of the Missouri River and occurs in the area which is Ozarkian both geologically and botanically.

Ranges from Georgia and Oklahoma, north to New York, Pennsylvania, Ohio, Kentucky, and Missouri.

45 *Asplenium* \times *ebenoides* (Walking Spleenwort)47 *Asplenium* *Bradleyi* (Bradley's Spleenwort)48 *Asplenium* \times *Gravesii* (*A. Bradleyi* \times *A. pinnatifidum*)

This species is considered by Dr. Warren Wagner, Jr., to be a fertile hybrid, originating from a cross between *Asplenium montanum* (which does not occur in Missouri) and *A. platyneuron*, the Ebony Spleenwort.

8. *Asplenium* \times *Gravesii* Maxon Map 48

Known in Missouri only from Madison County, in the southeastern Ozarks, where it was collected on November 10, 1898, by Colton Russell from cliffs of the La Motte sandstone formation near Mine La Motte. The specimen was determined by Dr. Wagner.

The fern is also known from Pennsylvania and New Jersey. It is considered a hybrid between *Asplenium pinnatifidum* and *A. Bradleyi*, combining characters of each. It differs from *A. pinnatifidum* in the dark stipe,

merely acuminate instead of elongated tip of the leaf blade, and in the sessile lowermost pinnae, whereas from *A. Bradleyi* it differs in the slightly winged rachis, and in the less cut pinnae.

It is probable that with more intensive botanical exploration of the state, other hybrids, now known to occur within the genus *Asplenium*, or between *Asplenium* and *Camptosorus*, will be found in Missouri. Those which may be expected to occur are *Asplenium kentuckiense* McCoy (*A. platyneuron* \times *A. pinnatifidum*), *A. inexpectatum* E. L. Braun (*Camptosorus rhizophyllus* and *Asplenium Ruta-muraria* var. *cryptolepis*), and *A. Bradleyi* \times *A. platyneuron*. The origin of these hybrids is being investigated by Dr. Warren H. Wagner, Jr., and his associates.

22. *Camptosorus* Link Walking Fern

Usually rock-inhabiting evergreen ferns with stipes green except for dark brown base and with simple narrow blades which taper to a very long, slender rooting tip. The veins are arranged in a rather loose network. The sori are oblong or linear with the indusium attached along one side.

Camptosorus rhizophyllus (L.) Link Map 49

Spores mature May–October.

Usually occurring on mossy sheltered ledges and bluffs of limestone or dolomitic bluffs, or on calcareous boulders or talus of hills, but also found on sandstone, chert, or granitic rocks. Throughout southern and central Missouri in the Ozark and unglaciated prairie region, and north in the glaciated section of the state in favored sites to Andrew, Grundy,

Chariton, Randolph, Knox, and Clark counties, Ranges from Georgia and Oklahoma, north to Quebec, Ontario, and Minnesota.

Morton (Am. Fern Jour. 45: 26. 1955; 46: 153. 1956), Wherry (Guide to Eastern Ferns, 2nd ed. p. 135. 1948, U. of Penn. Press, Philadelphia), and others have suggested that the Walking Fern be transferred to the genus *Asplenium*, and be called *A. rhizophyllum* L. There is sound justification for this

Plate no. 6. 1. *Asplenium* \times *ebenoides*, \times $\frac{2}{7}$; a. Lower portion of fertile pinna, \times $\frac{6}{7}$; After Gleason, The New York Botanical Garden. 2. *Asplenium Bradleyi*, \times $\frac{4}{7}$; a. Portion of lower surface of fertile frond, \times $\frac{6}{7}$; After Gleason, The New York Botanical Garden. 5. *Athyrium pycnocarpon*, \times $\frac{2}{7}$, with portions of tip, middle, and base of frond; a. Pinna, showing venation, \times $\frac{2}{7}$. 6. *Athyrium Filix-femina* var. *Michauxii*, \times $\frac{2}{7}$; a. Tip of frond; b. Middle portion of frond; c. Base of frond. 7. *Woodsia obtusa*, \times $\frac{2}{7}$; a. Lower portion of fertile pinnule, \times $\frac{2}{7}$; After Gleason, The New York Botanical Garden. 8. *Cystopteris bulbifera*, \times $\frac{2}{7}$, with upper and lower portions of frond. 9. *Cystopteris fragilis* var. *fragilis*, \times $\frac{2}{7}$; a. Lower portion of fertile pinnule, \times $\frac{6}{7}$. 10. *Athyrium thelypteroides*, \times $\frac{2}{7}$.

PLATE NO. 6

49 *Camptosorus rhizophyllus* (Walking Fern)50 *Athyrium pycnocarpon* (Narrow-leaved Spleenwort)51 *Athyrium thelypteroides* (Silvery Spleenwort)

since, as Morton states, the elongated rooting tip is found in many species of *Asplenium*, and the veins in a network arrangement are found in several unrelated species of *Asplenium*.

This fern does well in terraria and wardian cases, and may be grown in the wild garden if given adequate shelter from drying winds and damp, mossy limestone rocks as a substrate medium.

23. *Athyrium* Roth.

Large ferns with soft, rather thin, deciduous fronds. Leaf-blades once to three times pinnate. Stipes greenish. Sori narrow and linear to oblong or hooked or horseshoe-shaped, covered by an indusium attached along one side.

- a. Leaf-blade only simply or once pinnate, the leaf-divisions (pinnae) nearly entire (without teeth) or only slightly toothed 1. *A. PYCNOCARPON*
- a. Leaf-blade either pinnate-pinnatifid (main leaf-divisions deeply lobed but not cut all the way to their midribs) or twice or more pinnately divided b
- b. Leaf-blade pinnate-pinnatifid (main leaf-divisions deeply lobed but not cut all the way to their midribs); ultimate segments of the pinnule more or less without teeth; rachis and midnerves of main leaf-divisions mostly with narrow scales; veins of leaf-lobes mostly not forked 2. *A. THELYPTEROIDES*
- b. Leaf-blade twice or more pinnate (main leaf-divisions divided to their midribs or still further divided); ultimate segments of the pinnule mostly with small teeth; rachis and midnerves of main leaf-divisions smooth; veins of leaf-lobes mostly forked 3. *A. FILIX-FEMINA*

1. *Athyrium pycnocarpon* (Spreng.) Tidestr.

Narrow-leaved Spleenwort Map 50
Athyrium angustifolium (Michx.) Milde [P & S, Pinkerton]

Spores mature July–September.

Rich wooded slopes or wooded floors of ravines or valleys near streams or their branches. Frequent in all the Ozark section, forming luxuriant stands in the rich hill soils of the counties along the Missouri River, north along the Mississippi River to Clark County, and west to Clay, Jackson, Pettis, Benton, Cedar, and McDonald counties. Absent from much of the unglaciated and glaciated prairie region, and from the southeastern Missouri lowlands.

Ranges from Quebec to Minnesota, south to Georgia and Louisiana.

This fern grows well in a wild garden, if provided with a woodland or protected situation with light well-drained rich soil.

2. *Athyrium thelypteroides* (Michx.) Desv.

Silvery Spleenwort Map 51
Athyrium acrostichoides (Sw.) Diels [P & S, Pinkerton]

Rich wooded slopes or wooded floors of ravines or valleys near streams or their branches. Eastern Missouri west to Macon, Boone, Phelps, Texas, and Howell counties. This fern occupies much the same types of rich soil habitats as *A. pycnocarpon*, but is much less common.

Ranges from Nova Scotia, Minnesota, and Iowa, south to Georgia, Louisiana, and Missouri.

This species, like the narrow-leaved spleenwort, does well in the wild garden, when provided with sufficient shade, protection from wind, and light rich soil.

3. *Athyrium Filix-femina* (L.) Roth.

Lady Fern Map 52
 The following three variations occur in Missouri:

52 • *Athyrium Filix-femina* var. *Michauxii* f. *rubellum* (Lady Fern)52 □ *Athyrium Filix-femina* var. *Michauxii* f. *elatus* (Lady Fern)52 x *Athyrium Filix-femina* var. *asplenoides* (Lady Fern)53 *Woodsia obtusa* (Blunt-lobed Woodsia)54 • *Cystopteris fragilis* var. *fragilis* f. *fragilis* (Common Fragile Fern)54 † *Cystopteris fragilis* var. *Mackayii* (Common Fragile Fern)54 x *Cystopteris fragilis* var. *protrusa* (Common Fragile Fern)54 □ *Cystopteris fragilis* var. *fragilis* f. *simulans* (Common Fragile Fern)

a. Leaf-blade widest near the base, the second or third pair of pinnae from the base the longest; stalked glands usually absent from the rachis and lower side of the midrib . . .

3a. *A. FILIX-FEMINA* var. *ASPLENIOIDES*

a. Leaf-blade widest near the middle, the fourth or fifth pair of pinnae from the base the longest; stalked glands usually occurring on the rachis and the lower side of the midrib. b

b. Sun form with fertile fronds (with spores attached to under surface) more contracted and leathery than the sterile ones; sori coming together and covering lower side of fertile leaf-divisions at maturity . 3b. *A. FILIX-FEMINA* var. *MICHAUXII* f. *ELATIUS*

b. Shade form with fertile and sterile fronds of more or less similar appearance; sori mostly remaining separate from one another at maturity . . . 3c. *A. FILIX-FEMINA* var. *MICHAUXII* f. *RUBELLUM*

3a. *Athyrium Filix-femina* var. *asplenoides*

(Michx.) Farw. Map 52
Athyrium asplenoides (Michx.) Desv. [P & S, Pinkerton]

Spores mature July–October.

Rich wooded slopes and floors of ravines, along creeks and spring branches, or in wooded valleys along larger streams, rarely on moist sandstone or granitic ledges or bluffs. Southern and central Missouri, north to Jackson, Boone, and Lincoln counties.

Ranges from Florida to Texas, north to Massachusetts, New York, Ohio, Indiana, Missouri, and Oklahoma.

This fern grows well in a wild garden when provided with a loose humusy soil and a sheltered location.

3b. *Athyrium Filix-femina* var. *Michauxii*

(Spreng.) Farw. f. *elatus* (Link) Clute Map 52
Athyrium angustum var. *elatus* (Link) Butters [P & S]
Athyrium angustum in part [Pinkerton]

In similar habitats to those of var. *asplenoides*. This form is the rarest of the three variations encountered in Missouri, and occurs in only a few counties in eastern Missouri. Some authors consider it only an ecological variation, responding to a greater amount of sun.

Ranges from Quebec, Manitoba, and Minnesota, south to Maryland and Missouri.

3c. *Athyrium Filix-femina* var. *Michauxii*

f. *rubellum* (Gilbert) Farwell Map 52
Athyrium angustum var. *rubellum* (Gilbert) Butters [G]

Athyrium angustum in part [Pinkerton]

Spores mature June–October.

In similar situations to those of var. *asplenoides*. The variety is comparatively rare in the Ozark region, where it is replaced by var. *asplenoides*, but is the common variety in glaciated northern Missouri, where it is found on wooded hills and in ravines bordering creeks and their tributary branches.

Ranges from Labrador to Manitoba, south to Virginia, Indiana, Illinois, Missouri, and South Dakota.

24. *Woodsia* R. Br.*Woodsia*

Low-growing, tufted ferns with pinnately divided fronds. Indusium star-shaped or lobed, arising beneath the sorus, the lobes of the indusium curving rather symmetrically around the sorus.

***Woodsia obtusa* (Spreng.) Torr.**

Blunt-lobed *Woodsia* Map 53
Spores mature May–October.

Moist or dry, mossy, shaded, or sometimes exposed ledges or bluffs of limestone, sandstone, chert, or granitic rocks, and rocky open wooded slopes and banks. Widespread and common throughout the state,

but apparently absent in the extreme northwestern part and in the southeastern lowlands.

Ranges from Nova Scotia to Minnesota, south to Florida and Texas.

Sometimes confused with *Cystopteris fragilis*, but can be distinguished by having the scales on the rachis.

25. *Cystopteris* Bernh. Bladder Fern

Delicate ferns with deciduous, finely pinnately cut fronds. Indusium attached at the base of and partly at one side of the somewhat round sorus, and becoming arched or hood-like over the sporangia.

Leaf-blade broadest above the base; veins of leaf segments usually ending in a tooth; tip of leaf-blade acute or acuminate; undersurface of leaf-blade never bearing rounded bulblets 1. *C. FRAGILIS*
Leaf-blade broadest at the base; veins of leaf segments running to a notch (sinus); tip of leaf-blade long-tapering; undersurface of leaf-blade often bearing rounded bulblets 2. *C. BULBIFERA*

1. *Cystopteris fragilis* (L.) Bernh.

Common Fragile Fern Map 54

This may be mistaken for *Woodsia obtusa*, but is separated from that species by the absence of hairs, scales, or glands on the leaf-blade.

The following variations occur in Missouri:

- a. Plants growing in soil; rhizome long-creeping with the growing point prolonged 2–5 cm. beyond the fronds; basal pinnules of the larger main leaf-divisions (pinnae) stalked, cuneate (acutely narrowed) at base. 1d. *C. FRAGILIS*
var. *PROTRUSA*
- a. Plants usually growing on rocks or on rocky ledges; rhizome short and contracted, not long creeping, the growing point not prolonged beyond the fronds; basal pinnules of the larger main leaf-divisions (pinnae) sessile (stalkless) or nearly sessile b
- b. Indusium about 0.5 mm. long, without teeth (entire) or merely shallowly cleft; basal segments of pinnule of the main leaf-divisions (pinnae) cuneate (acutely narrowed) at the base 1c. *C. FRAGILIS*
var. *MACKAYII*
- b. Indusium up to 1 mm. long, becoming deeply cleft at the tip; basal segments of pinnule of the main leaf-divisions (pinnae) broadened at base c
- c. Lower and larger main-divisions (pinnae) lanceolate or narrowly lanceolate-ovate, one-third to one-half as broad as long. 1a. *C. FRAGILIS* var. *FRAGILIS* f. *FRAGILIS*

- c. Lower and larger main-divisions (pinnae) deltoid-ovate, one-half to five-sixths as broad as long . . . 1b. *C. FRAGILIS*
var. *FRAGILIS* f. *SIMULANS*

1a. *Cystopteris fragilis* (L.) Bernh. var. *fragilis* f. *fragilis* Map 54

Cystopteris fragilis in part [P & S, Pinkerton]

Cystopteris fragilis [G]

Spores mature June–September.

Moist shaded recesses of mostly limestone and sandstone bluffs, sometimes on cherty and granitic sheltered ledges or outcrops with moist mossy pockets. This variety is found scattered over sections of the state, but is not as common as var. *protrusa*.

Ranges from Labrador to Alaska, south to North Carolina, Texas, and California; also in Eurasia.

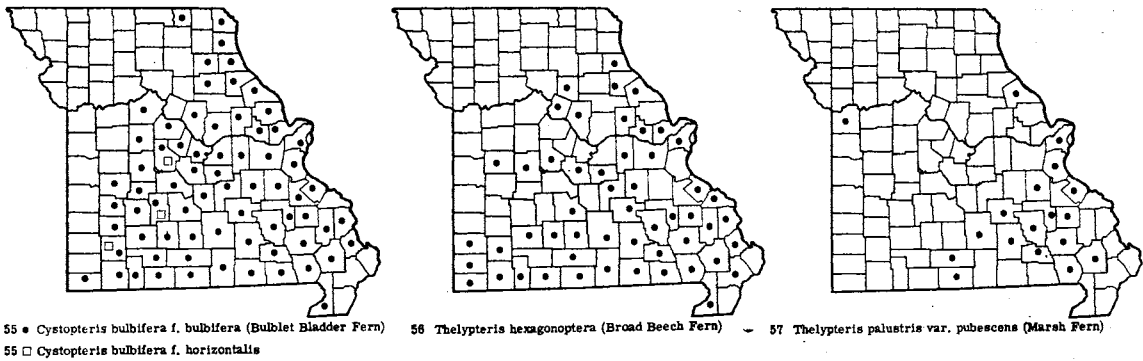

1b. *Cystopteris fragilis* var. *fragilis* f. *simulans* Weath. Map 54

The habitat is the same as that of var. *fragilis*, with which it frequently is associated.

Known from Illinois and Tennessee to Missouri and Texas.

1c. *Cystopteris fragilis* var. *Mackayii* Lawson Map 54

The habitat is similar to that of var. *fragilis*. This variety is of frequent occurrence throughout the state, but not as common as var. *protrusa*.

Ranges from Nova Scotia to North Dakota, south to Virginia and Missouri.

1d. **Cystopteris fragilis** var. **protrusa** Weath. Map 54

Rich wooded slopes, wooded floors of ravines or of river valleys, and banks along streams. This is the commonest variety in Missouri, and is found throughout the state.

Ranges from New York to Minnesota and Nebraska, south to Georgia, Louisiana, and Oklahoma.

The habitat of this variety which is on the ground in soil, instead of on rocks, readily distinguishes it from the other varieties. This variety is easily grown in wild gardens where given sufficient shade. The fronds die down to the ground during summer.

2. **Cystopteris bulbifera** (L.) Bernh. Map 55
Bulblet Fern, Bladder Fern

The following two forms may be distinguished:

- Leaf-blade long-tapering at tip; common type 2a. *C. BULBIFERA* f. *BULBIFERA*
Leaf-blade not long-tapering at tip; rare type 2b. *C. BULBIFERA* f. *HORIZONTALIS*

2a. **Cystopteris bulbifera** f. **bulbifera** Map 55
Cystopteris bulbifera in part [P & S, Pinkerton]
Spores mature June–September.

Shaded, usually damp or mossy ledges, talus, or lower rocky portion of usually limestone bluffs, rarely on sandstone or granitic rocks. Throughout the Ozark region and counties bordering the Ozarks north to Schuyler and Clark counties, west to McDonald, Lawrence, St. Clair, Pettis, Saline, Boone, and Shelby counties; absent from the lowlands of southeastern Missouri, from most of the northwest and north-central sections, and from most of the unglaciated prairie region.

Ranges from Newfoundland, Manitoba, and Utah, south to Georgia, Arkansas, and Arizona.

Bulblets are often absent from the fronds, but, when present, offer a useful character in readily distinguishing this from the Fragile Fern (*C. fragilis* var. *fragilis* and other varieties). This fern does well in a shaded rock garden when provided with calcareous rocks in a sheltered, damp location.

2b. **Cystopteris bulbifera** f. **horizontalis** Map 55
(Lawson) Gilbert
Associated with f. *bulbifera*, but of rather infrequent occurrence.

26. **Thelypteris** Schmidel

Ferns with deciduous fronds and slender, creeping rhizomes. The leaf-blade has a hairy rachis. The fertile blades are similar to the sterile ones. The round sori are covered by a heart-shaped indusium, or in *T. hexagonoptera* the indusium is absent.

Ferns of dry or rich woods or wooded slopes; leaf-blades triangular, definitely broadest at the base; main leaf-divisions (pinnae) not divided all the way to the midrib (rachis), but connected at their bases by green tissue 1. *T. HEXAGONOPTERA*

Ferns of swamps and wet ground along streams and in wet thickets; leaf-blades lanceolate, the lowest main leaf-divisions (pinnae) about same length or shorter than the middle ones; main leaf-divisions (pinnae) divided all the way to the midrib (rachis), not connected at their bases by any green tissue 2. *T. PALUSTRIS* var. *PUBESCENS*

58 • *Dryopteris austriaca* var. *spinulosa* (Spinulose Shield Fern)59 *Dryopteris marginalis* (Marginal Shield Fern)60 *Dryopteris Goldiana* (Goldie's Fern)58 □ *Dryopteris austriaca* var. *intermedia*

1. ***Thelypteris hexagonoptera*** (Michx.) Weath.
Broad Beech Fern Map 56
Dryopteris hexagonoptera (Michx.) Christens. [G]
Spores mature June–September.

Usually occurring in acid soils of rocky wooded, often dry slopes or floors of ravines, frequently in areas of sandstone, chert, or granitic rocks. Common throughout most of the Ozark section of the state, west to McDonald, Jasper, Laclede, Henry, and Howard counties, and north to Randolph and Marion counties.

Ranges from Florida and Texas, north to Quebec, Maine, Ontario, and Minnesota.

An indusium is absent. This fern thrives in shaded wild gardens where the soil is somewhat acid and covered with decayed leaves (oak, especially).

2. ***Thelypteris palustris*** Schott, var. ***pubescens***
(Lawson) Fern. Marsh Fern Map 57

Dryopteris Thelypteris (L.) Gray, var. *pubescens* (Lawson) Nakai [G]
Spores mature June–October.

Usually in swampy ground, either in woods, thickets, or wet open meadows where springs and spring branches are located. The fern is often found in wet swampy meadows kept moist by springs issuing from calcareous strata, but also occurs on more acid, moist soils. Mostly encountered in the eastern half of the Ozark region, west to Dent, Texas, and Ozark counties, and locally north and west to Pike and Jackson counties.

Ranges from Newfoundland to Manitoba, south to Georgia and Oklahoma. Other varieties occur in the southern United States, West Indies, South Africa, Eurasia, and New Zealand.

An indusium is present. Not suitable for the wild garden unless provided with a constantly moist soil.

27. *Dryopteris* Adans. Shield Fern

Ferns with mostly dark green, thickish, evergreen or nearly evergreen leaf-blades. Rhizomes stout, covered with the bases of the old leaf-stalks (stipes). Indusium horseshoe-shaped, rather conspicuous.

- a. Teeth on ultimate segments of leaf-blades ending in bristle-like tips; leaf-blade mostly twice or thrice pinnate (each main division again divided to its midrib), or the smaller divisions likewise divided; at least the basal pinnules (innermost lowermost ultimate divisions) of the basal pinnae (lowermost main divisions) with stalks; lower pinnae (main leaf-divisions) conspicuously unequal-sided 1. *D. AUSTRIACA* var. *SPINULOSA* and var. *INTERMEDIA*
a. Teeth on ultimate segments of leaf-blades not ending in bristle-like tips; leaf-blade with main leaf-

Plate no. 7. 1. *Thelypteris palustris* var. *pubescens*, $\times \frac{2}{7}$; a. Pinna showing venation, $\times 2$; After Gleason, The New York Botanical Garden. 2. *Dryopteris austriaca* var. *spinulosa*; a. Tip of frond; b. Base of frond; c. Middle portion of frond. 3. *Thelypteris hexagonoptera*, $\times \frac{2}{7}$; a. Lobe of portion of pinna, lower surface, $\times \frac{6}{7}$. 4. *Dryopteris Goldiana*, $\times \frac{2}{7}$; a. Tip of frond; b. Middle portion of frond; c. Base of frond; d. Fertile pinnule, lower portion, $\times \frac{6}{7}$. 5. *Dryopteris Clintoniana* var. *australis*, $\times \frac{2}{7}$; a. Upper part of fertile frond, lower surface; b. Lower part of frond, upper surface; After Gleason, The New York Botanical Garden. 6. *Dryopteris marginalis*, $\times \frac{2}{7}$; a. Tip of frond; b. Middle portion of frond; c. Base of frond; d. Fertile pinnule, lower portion, $\times \frac{1}{7}$. 7. *Polystichum acrostichoides*, $\times \frac{2}{7}$; a. Upper half of frond, upper surface; b. Lower half of frond, upper surface; c. Fertile pinna, lower surface, $\times \frac{2}{7}$; After Britton and Brown, The New York Botanical Garden.

PLATE NO. 7

- divisions (pinnae) deeply pinnatifid (cut nearly to their midrib) or almost twice-pinnate; basal pinnules of the basal pinnae without stalks (sessile); lower pinnae more or less equal-sided b
- b. Margins of ultimate segments smooth, or if toothed, the teeth blunt or rounded; sori located along the margins of the leaf segments 2. *D. MARGINALIS*
- b. Margins of ultimate segments with pointed teeth; sori nearer midribs of the leaf segments c
- c. Lowest pinnae (main leaf-divisions) with usually 12–18 pairs of pinnules (ultimate segments), the pinnae located in the middle part of the leaf-blade with 14–22 pairs; pinnae (main leaf-divisions) broadest above the base, the inner basal (lowermost) segment of the lowest pinnae shorter than the next one 3. *D. GOLDIANA*
- c. Lowest pinnae with 20–31 pairs of pinnules (ultimate segments); pinnae (main leaf-divisions) broadest at the base, the inner basal (lowermost) segment of the lowest pinnae noticeably longer than the next one 4. *D. CLINTONIANA* var. *AUSTRALIS*

1. ***Dryopteris austriaca*** (Jacq.) Woynar

Spinulose Shield Fern Map 58

The following two varieties are found in Missouri, and are semi-evergreen:

Basal (lowermost) pinnule (ultimate leaf-division) of the lower side of the lowest pinnae (main leaf-divisions) longer than the next one; indusium and leaf-blade not glandular 1a. *D. AUSTRIACA*

var. *SPINULOSA*

Basal pinnule of the lower side of the lowest pinnae shorter than or equaling the next one; indusium and frequently the leaf-blade glandular 1b. *D. AUSTRIACA* var. *INTERMEDIA*

1a. ***Dryopteris austriaca*** var. ***spinulosa*** (Müll.)

Fiori Map 58

Dryopteris spinulosa (O. F. Muell.) Watt. (typical) [G]

Thelypteris spinulosa (Muell.) Nieuwl. [P & S, Pinkerton]

Spores mature June–October.

Shaded crevices of moist St. Peter sandstone bluffs in Jefferson County and on bald cypress knees in wooded swamp in Butler County (*Colton Russell*, October 30, 1899).

Ranges from Quebec to Minnesota and British Columbia, south to Virginia, Kentucky, and Missouri.

1b. ***Dryopteris austriaca*** var. ***intermedia*** (Muhl.)

Morton Map 58

Dryopteris spinulosa var. *intermedia* (Muhl.) Underw. [G]

Thelypteris spinulosa var. *intermedia* (Muhl.) Nieuwl. [P & S, Pinkerton]

Shaded crevices of moist St. Peter sandstone bluffs in Jefferson County, moist La Motte sandstone bluffs in Ste. Genevieve and Madison counties, and wooded swamps of Stoddard and Butler counties, all the known stations occurring in eastern Missouri south of the Missouri River.

Ranges from Newfoundland, Ontario, and Minnesota, south to Georgia and Missouri.

2. ***Dryopteris marginalis*** (L.) Gray

Marginal Shield Fern, Evergreen Wood Fern

Map 59

Spores mature June–October.

Commonly in shaded crevices of sandstone, chert, or granitic ledges and bluffs, in acid soils, more rarely on talus of rocky wooded slopes; occurring in most counties of the Ozarks on sandstone, west to Newton, Vernon, and Benton counties; in the counties bordering the Missouri River on St. Peter sandstone, locally north in Lewis and Shelby counties, and west locally in Saline County.

Ranges from Nova Scotia and Ontario to Wisconsin, south to Georgia, Arkansas, and Oklahoma.

This fern does well in wild or rock gardens, if provided with sufficient shade, protection from wind, and good drainage. It prefers an acid rocky situation.

3. ***Dryopteris Goldiana*** (Hook.) Gray

Goldie's Fern

Map 60

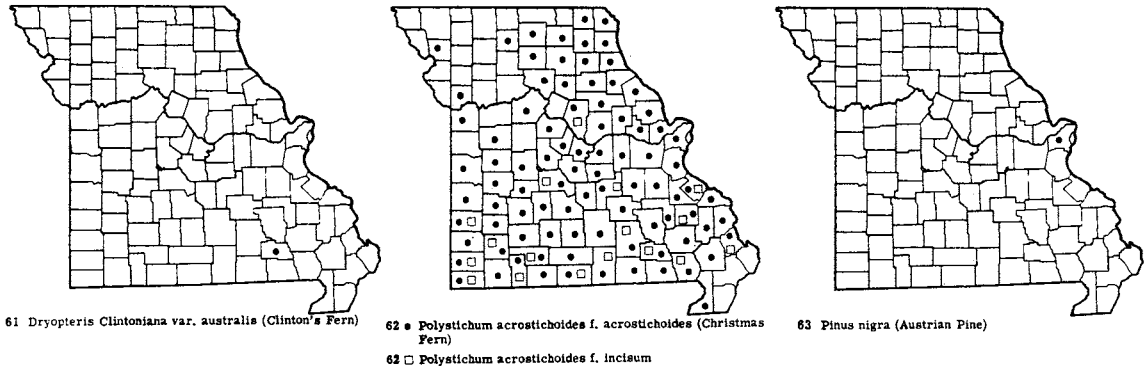

Spores mature June–September.

Known from two isolated stands, one from a north-facing bluff of St. Peter sandstone in a ravine tributary to Dry Fork of Charrette Creek, 6 miles south of Warrenton in Warren County (*Steyermark 73069*), and the second from rich woods at the base of a north-facing slope of a spring-fed branch 1½ mi. east of Marquand, in Madison County, near the Bollinger County line (*Steyermark 77555*).

Ranges from New Brunswick and Ontario to Minnesota, south to South Carolina, Tennessee, and Missouri.

This is one of the most handsome and stately ferns. The fronds are nearly evergreen, and usually last well into early winter before dying.

This fern does well in wild flower gardens or around foundation plantings if given rich soil, leaf mold, and a protected, shaded situation.

4. *Dryopteris Clintoniana* (D. C. Eaton) Dowell
var. *australis* Wherry Clinton's Fern

Map 61

Dryopteris cristata var. *Clintoniana* in part [G]
Spores mature May–July.

One of the rarest ferns of Missouri, known only from the original station discovered in 1938 in Carter County, southeastern Ozark region (*Steyermark* 5333), around outlet of Blue Spring, tributary to Big Barren Creek, 10 miles northwest of Bennett.

Ranges from the Gulf Coast to Pennsylvania, northwest to Missouri.

The status of this fern is controversial. Wherry recognized it as a variety of *D. Clintoniana*, Fernald merged it with var. *Clintoniana* under *D. cristata*, while by others it has been questioned as being a hybrid with *D. ludoviciana* (Kunze) Small. The most recent studies by S. Walker (*Am. Fern Jour.* 49: 108, 1959) suggest that it is a triploid hybrid, with *D. ludoviciana* as one of its parents.

28. *Polystichum* Roth.

Terrestrial ferns with thick evergreen pinnate (in Missouri species) blades. Indusium round, attached at the center only, the round sorus opening on all sides of the center of attachment of the indusium.

Polystichum acrostichoides (Michx.) Schott
Christmas Fern Map 62

Two forms are recognizable in Missouri:

- Main leaf-segments (pinnae) minutely toothed, with shallow, slanting teeth . . . 1a. *P. ACROSTICHOIDES*
f. *ACROSTICHOIDES*
Main leaf-segments coarsely toothed, especially the lower ones more deeply toothed
1b. *P. ACROSTICHOIDES* f. *INCISUM*

sometimes luxuriating along moist mossy banks or moist rock ledges. Occurring in all except the counties of northwestern and extreme southeastern Missouri, and absent from some northern and west-central counties.

Ranges from Nova Scotia to Wisconsin, south to Florida, Texas, and Mexico.

A satisfactory fern for the wild garden, but preferring well-drained slopes with protection from wind and sun.

1a. *Polystichum acrostichoides*
f. *acrostichoides* Map 62

Spores mature June–October.

On dry or moist, but well-drained wooded slopes, generally on the more acid soils, where often associated with sandstone, chert, or granitic rocks, attaining its best development on north-facing slopes, in narrow ravines, or at the base of talus slopes in acid soil;

1b. *Polystichum acrostichoides* f. *incisum*
(Gray) Gilbert Map 62
Polystichum acrostichoides var. *incisum* Gray [Pinkerton]

Frequently occurring with typical f. *acrostichoides*, but less common. Scattered in sections of southern and central Missouri.

Division II

Spermatophyta

Class 1. GYMNOSPERMAE

Ovules pollinated directly without being enclosed within an ovary, usually in an open scale.

Order CONIFERAE

- a. Leaves not evergreen, falling in late autumn, set singly on two sides of the stem; in swamps of southeastern Missouri 2. TAXODIUM in Taxodiaceae
- a. Leaves evergreen, persistent, in clusters of 2-3, or scale-like b
- b. Leaves in clusters of 2 or 3, at least 2.5 cm. long 1. PINUS in Pinaceae
- b. Leaves usually scale-like, but, if needle-like on some branches, less than 1 cm. long 3. JUNIPERUS in Cupressaceae

PINACEAE (Pine Family)

1. *Pinus* L. Pine

The pollen shed by species of pine is very abundant, but is mostly harmless, so far as hay fever is concerned. American Indians and Europeans have used the inner bark of various species of pine as food, in Europe mixing the ground dried bark with other flour as a type of bread. *Pinus sylvestris*, the Scotch Pine, commonly cultivated in Missouri, was especially used in northern Europe. The inner bark of various pines may be cut into strips and chewed in the spring for the spicy taste.

- a. Leaves 3-7 cm. long 3. *P. VIRGINIANA*
- a. Leaves 7-15 cm. long b
- b. Native Ozark species; new leafy shoots of spring with more than 1 whorl (circle) of branchlets; young branches glaucous (with a 'bloom' that can be rubbed off) 2. *P. ECHINATA*
- b. Introduced tree, escaped from cultivation; new leafy shoots of spring with only 1 whorl of branchlets; young branches not glaucous 1. *P. NIGRA* var. *NIGRA*

1. *Pinus nigra* Arnold var. *nigra*

Austrian Pine

Map 63

Occasionally persisting from an original planting, as in St. Louis County, where a few trees have persisted in a wooded valley north of highway 66 west of Peerless Park.

The tree, a native of Europe, is common in culti-

vation. It will doubtless be found in other localities where it has adapted to a wild situation.

2. *Pinus echinata* Mill. Short-leaf Pine Map 64

On acid, non-calcareous soils, associated with sandstone, chert, or granitic rocks, in rocky wooded ravines, bluffs, steep slopes, tops of narrow

Plate no. 8. 1. *Pinus echinata*, $\times \frac{2}{5}$; a. Male flowering branch; b. Branch with fruit; c. Female flowering branch. 2. *Pinus virginiana*; a. Male flowering branch, $\times \frac{2}{5}$; b. Fruit and leafy branch, $\times \frac{2}{5}$; c. Female flowering branch, $\times \frac{2}{5}$. 3. *Pinus nigra*; a. Fruit, $\times \frac{2}{5}$; b. Leafy branch, $\times \frac{2}{5}$; c. Cluster of leaves, $\times \frac{2}{5}$. 4. *Taxodium distichum*, $\times \frac{2}{5}$; a. Male flowering branch; b. Leafy branch with fruit; Details from Small, The New York Botanical Garden.

PLATE NO. 8

64 *Pinus echinata* (Short-leaf Pine)65 *Pinus virginiana* (Scrub Pine)66 • *Taxodium distichum* f. *distichum* (Bald Cypress)
66 □ *Taxodium distichum* f. *confusum*

ridges, dry uplands, or in valleys along streams where the soil has sandy, chert, or granitic components.

Confined to the Ozark region, extending west to McDonald, Christian, Wright, Laclede, and Pulaski counties, and north to Phelps, Franklin, and Jefferson counties.

Ranges from Florida and Texas, north to New York, West Virginia, Ohio, Southern Illinois, Missouri, and Oklahoma.

An important lumber tree in Missouri. Its wood pulp is employed for papermaking.

3. *Pinus virginiana* Mill. Scrub Pine Map 65

Like the Austrian Pine, this tree is planted and occasionally is found away from cultivation, having become established in a natural wild environment in Callaway County (*Steyermark 18515*) at the head of a ravine between Calwood and Fulton. Records from St. Louis County are from trees that are growing in cultivated sections of estates.

Native of the United States, ranging from Georgia to Arkansas, north to New York, New Jersey, West Virginia, Ohio, and Indiana; introduced in Missouri through plantings.

TAXODIACEAE (Bald Cypress Family)

2. *Taxodium* Rich. Bald Cypress

Taxodium distichum (L.) Rich.

Bald Cypress

Map 66

Two variations may be noted in Missouri:

Leaves spreading or diverging at a noticeable angle from the branches; tips of branches spreading or outwardly curving; common type . . . 1a. *T. DISTICHUM* var. *DISTICHUM* f. *DISTICHUM*
Leaves lying close to (appressed) the branches; shorter and more crowded; tips of branches upwardly curving; rare type . . . 1b. *T. DISTICHUM* var. *DISTICHUM* f. *CONFUSUM*

1a. *Taxodium distichum* var. *distichum* f. *distichum*

Map 66

Swamps, bayous, and alluvial soils along streams and lowlands in southeastern Missouri north to Cape Girardeau, Bollinger, Wayne, and Ripley counties. Reported by Beilmann as estab-

lished, away from cultivation, in St. Louis County.

Ranges from Florida and Texas north to New Jersey, southern Indiana, southern Illinois, southeastern Missouri, Arkansas, and Oklahoma.

In the fall the leaves turn from a rich green to russet or cinnamon-brown.

1b. *Taxodium distichum* var. *distichum* f. *confusum*

Palmer & Steyermark Map 66

Occurring within the range of and with the common type, and known from Wayne County (*Steyermark 11261*, holotype in Mo. Bot. Gard. Herbarium) and Butler County.

Known also from stations in southern Illinois and Arkansas.

This is a form which is more frequently found in sunny or exposed situations, and is probably only an ecological variant.

Fam. CUPRESSACEAE (Cypress Family)

3. Juniperus L. Cedar

Trees of this genus are usually either male or female (dioecious), the female bearing the fruit.

The roasted berries of some species of juniper are sometimes used as a coffee substitute. The berries of the common juniper (*Juniperus communis* var. *communis*) are used as an ingredient of gin. In parts of northern Europe an edible pulp is extracted from the berries of the juniper and often eaten with bread.

Along White River and tributaries of southwestern Missouri only; scale-like leaves minutely denticulate (toothed) when viewed with a lens; seeds 1, rarely 2 per berry, sharply pointed, 4–5 mm. in diam.; no pits on seed; conspicuous white growth (hilum) on seed; trunk of tree more or less branched near the base; fruit 6–8 mm. in diam.; glands on leaves round, raised well above the leaf 2. J. ASHEI

Common throughout Missouri; scale-like leaves with entire (toothless) margins; seeds 1 or 2 per berry, or 3–6, blunt-tipped, 2–3 mm. in diam.; numerous pits on seed; small inconspicuous white growth (hilum) on seed; trunk of tree solitary, unbranched near base, erect; fruit 3.5–5 mm. in diam.; glands on leaves elongated or longer than broad, not raised or rarely raised above the leaf. 1. J. VIRGINIANA

- 1. **Juniperus virginiana** L. Red Cedar Map 67
Two variations occur:
Crown of the tree ovoid (broadly egg-shaped), rather broad with widely spreading branches; seeds conspicuously pitted; common type
1a. J. VIRGINIANA var. VIRGINIANA
Crown of the tree narrowly pyramidal-shaped, with strongly ascending branches; seeds rather inconspicuously pitted; rarer type . 1b. J. VIRGINIANA var. CREBRA

1a. **Juniperus virginiana** var. **virginiana** Map 67

In Missouri this occurs most commonly on limestone bluffs and open glades, borders of woods, old fields, pastures, and fence rows, less commonly on sandstone, chert, or granitic rocks. Occurs in all the counties except those of the extreme southeastern lowlands.

Ranges from Alabama and Texas, north to southern New England, Kentucky, and Missouri.

The red cedar wood is employed in the manu-

facture of lead pencils, chests, cigar boxes, and fence posts. The wood left over from the products manufactured is one of the principal sources of cedarwood oil, which is employed in the manufacture of soaps, furniture polish, sanitary supplies, and perfumes. The refined oil, because of its high index of refraction, is used in oil immersion microscopes. An oil which comes from the leaves is used for ointments, liniments, bath salts, soap, and shoe polishes.

A variation of Red Cedar, with spreading branches and slender drooping branchlets is known as *J. virginiana* var. *pendula* Carr., and is recorded from Clark Co.

- 1b. **Juniperus virginiana** var. **crebra**
Fern. & Grisc. Map 67
This variety with a narrowly pyramidal form is infrequently found in Missouri, and is known from limestone bluffs in Knox County (*Steyermark 10875*) along the South Fork of Fabius River, 3 miles northwest of Newark, and from Jefferson County.

Ranges farther north than typical var. *virginiana*,

extending north to Maine, Quebec, Ontario, Minnesota, and North Dakota.

Dr. Norman Fassett (Bull. Torr. Bot. Club 72: 42-46, 480-82. 1945; and 71: 410-18, 475-83. 1944) has discussed the variation of *J. virginiana* var. *virginiana* and var. *crebra*.

2. **Juniperus Ashei** Buchholz Ashe's Juniper
Map 68
Juniperus mexicana Spreng. [G, BB, P & S, Steyerl.]

Limestone glades and bald knobs along bluffs of the White River and tributaries in southwestern Missouri from Barry County east to McVey Knob, Ozark County.

Also occurs in northern Arkansas, Arbuckle Mountains and bluffs of Pryor Creek in Oklahoma, and in parts of Texas, especially the Edwards Plateau section.

Dr. M. T. Hall (Ann. Mo. Bot. Gard. 39: 1-64. 1952) has discussed the variation of this species and *J. virginiana*.

Class 2. **ANGIOSPERMAE**

Ovules enclosed within a closed ovary. Flowers with a perianth present or absent.

Subclass 1. **MONOCOTYLEDONEAE**, Monocotyledons

Embryo with one cotyledon. Woody (vascular) bundles scattered and separate in the stem, appearing as dots scattered through the tissue. Parts of flowers often in 3's or 6's, sometimes in 2's or 4's, never in 5's. Leaves usually parallel-veined (but there are many exceptions).

Order **PANDANALES**

Fam. **TYPHACEAE** (Cat-tail Family)

Typha L. (Cat-tail)

- a. Flowering spikes continuous, the male (staminate) part not separated from the female (pistillate) part 1a. *T. LATIFOLIA* f. *LATIFOLIA*
- a. Flowering spikes with the male (staminate) part separated from the female (pistillate) part by a naked axis b
- b. Pollen grains in 4's; surface of female (pistillate) part with minute dark or blackish markings; flowers from female (pistillate) part with flattened lance-ovate stigmas . . . 1b. *T. LATIFOLIA* f. *AMBIGUA*
- b. Pollen grains single; surface of female (pistillate) part without dark or blackish markings; flowers from female (pistillate) part with thread-like stigmas c
- c. Female (pistillate) spike 6-15 mm. in diameter; leaves 3-8 mm. wide; stigmas (from female spike) with many dark brown bracts occurring down among the hairs 2. *T. ANGUSTIFOLIA*
- c. Female (pistillate) spike 16-22 mm. in diameter; leaves 7-15 mm. wide; stigmas (from female spike) without any bracts or merely a few bracts occurring down among the hairs . . . 3. *T. GLAUCA*

1. **Typha latifolia** L. Common Cat-tail Map 69

- 1a. **Typha latifolia** f. *latifolia* Map 69

Flowers late May-July. This is the common type, found throughout Missouri in swamps, muddy margins of ponds and streams, and other wet places.

Ranges throughout North America, and in Eurasia and North Africa.

Although much pollen is shed from the male (staminate) spike, it does not cause hay fever.

This and other species of cat-tail are used in a number of ways. The leaves supply the rush seats for chairs which several companies today manufacture. The American Indian made floor mats from the leaves, which, together with the leaf sheaths, supplied him caulking material.

Plate no. 9. 1. *Juniperus virginiana*; a. Habit greatly reduced; b. Normal mature leafy branch with fruit, $\times \frac{2}{7}$; c. Young or juvenile branch, $\times \frac{2}{7}$; d. Single leaf, $\times \frac{8}{7}$; Details from Small, The New York Botanical Garden. 2. *Juniperus Ashei*; a. Habit, greatly reduced; b. Normal mature leafy branch with fruit, $\times \frac{2}{7}$; c. Single leaf, $\times \frac{8}{7}$; Details from Small, The New York Botanical Garden. 3. *Typha latifolia*, $\times \frac{2}{7}$; a. Female flower, $\times \frac{2}{7}$; b. Male flower, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 4. *Typha angustifolia* $\times \frac{2}{7}$; a. Female flower, $\times \frac{2}{7}$; b. Male flower, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 5. *Sparganium eurycarpum*; a. Leafy branch, $\times \frac{2}{7}$; b. Fruiting head, $\times \frac{2}{7}$; c. Female flower/head, $\times \frac{2}{7}$; d. Single female flower, $\times \frac{6}{7}$.

PLATE NO. 9

70 *Typha angustifolia* (Narrow-leaved Cat-tail)71 *Typha glauca*72 *Sparganium eurycarpum* (Bur-reed)

An attempt has been made to use the plants as a substitute for cotton, wool, and jute, for the manufacture of paper and ethyl alcohol, and the soft featherlike down from the mature fruiting spikes is used for its buoyancy in life jackets, and as a sound-proofing, and heat-insulating material. As a waste material it is being considered seriously in the paper-making industry. The seeds, which contain about 18% oil, of which some 70% is linolenic acid, are being tested as a drying oil as well as an edible oil.

Various portions of the plant may be used as food. The starchy rootstocks can be eaten raw in salad or cooked as a vegetable. A highly nutritious flour, containing 57% carbohydrate, is obtained from the central part of the rootstock. A jelly is also extracted from the root. The young stems are used in early spring as a vegetable. Perhaps the most interesting part for food is prepared from the young flowering spikes. Before the pollen has developed, the young staminate spikes are steamed or boiled in water to which salt has been added, and may be pickled, or after the flowers have been separated from the hard central axis, they may be cooked with eggs, milk, buttered crumbs, or oil. The pollen from the staminate flower spikes is also used to prepare a bread or cake-stuff, about twenty-five flower spikes being needed for preparing a small cake.

1b. *Typha latifolia* f. *ambigua* (Sonder) Kronf.

Map 69

Known only from Jasper (*Palmer 54921*) and Stoddard (*Steyermark 78660*) counties. In the latter locality it was found along a swampy spring branch at the base of Crowley Ridge near the junction with the flood plain, 5 miles northeast of Dexter, and occurred with the typical form of the species.

This form is sometimes confused with *T. angustifolia*, because of the separated spikes.

2. *Typha angustifolia* L.

Narrow-leaved Cat-tail
Flowers late May–July.

Map 70

Borders of muddy and calcareous ponds and in shallow water of natural brine lakes. Scattered throughout the western half of the state, where very rare and local.

Ranges from Nova Scotia and Maine to Quebec and Ontario, south to South Carolina, Kentucky, Missouri, and Nebraska; also in California and Eurasia; especially common along the brackish water estuaries of the Atlantic Coast.

Narrow-leaved specimens of *T. latifolia* are often confused with this species.

Dr. Norman Fassett (*Evolution 6*: 367–79. 1952) has presented evidence pointing to the occurrence of hybridization between *T. latifolia* and *T. angustifolia*.

3. *Typha glauca* Godr.

Map 71

Typha angustifolia var. *elongata* (Dudley) Wieg. [BB]
Flowers late May–July.

Thus far, known only from Platte County (marshy area near Basswood Lakes, 4 miles east of Platte City, July 12, 1956, *Radloff*), and from Boone County (border of Moore's lake of Power and Light Co., just north of highway 40, Columbia, July 31, 1958, *Steyermark 86146*, and *Dunn 12945*).

Ranges from Maine, Ontario, Iowa, and South Dakota, south to North Carolina, Alabama, and Missouri; also in California and reported from Guatemala.

Although Dr. Fassett (*Fassett, N. C. and Barbara Calhoun, Introgression between Typha latifolia and T. angustifolia. Evolution 7, no. 4. December. 367–79. 1952*) considers this taxon a series of individuals in hybrid swarms, other botanists, such as Drs. Hotchkiss and Dozier, who have carried on special investigations, consider *T. glauca* a distinct species (*Am. Midl. Nat.* 41: 237–54. 1949).

SPARGANIACEAE (Bur-reed Family)

Sparganium L. Bur-reed

It is reported that the Klamath Indians dig the tubers produced in late autumn from the creeping rootstocks of some of the species of this genus, and use them as food.

The individual flowers are small and occur in separate male (staminate) or female (pistillate) globular clusters on the same plant.

- a. Stigmas 2 to each female (pistillate) flower; fruits sessile, wedge-shaped and widest at summit or in the upper half. 1. *S. EURYCARPUM*
- a. Stigmas 1 to each female (pistillate) flower; fruits narrowed to a stalk-like base, and tapering above, widest around the middle, or at least not conspicuously broadened above. b
- b. Stigma 2-4 mm. long; leaves firm and stiff, at least the middle leaves keeled; fruit shining, its body 5.5-7 mm. long, its beak 4-6 mm. long 2. *S. ANDROCLADUM*
- b. Stigma 1-2 mm. long; leaves rather soft, flat or only inconspicuously keeled; fruit dull, its body 3-5 mm. long, its beak 3-4.5 mm. long 3. *S. AMERICANUM*

- 1. *Sparganium eurycarpum* Engelm. Map 72
Flowers May-August.

Common on the margins of oxbow lakes and sloughs along the larger rivers, and in swampy ground in the valleys of the Missouri, Mississippi, South Grand and tributaries, and Grand River and tributaries in eastern, northern, and central Missouri.

Ranges from Quebec and Nova Scotia to British Columbia, south to New Jersey, Ohio, Indiana, Illinois, Missouri, Kansas, Colorado, and California.

This species has a persistent creeping rhizome and stiff erect leaves. It grows taller than the other species in Missouri, reaching a height of 1.5 meters.

- 2. *Sparganium androcladum* (Engelm.) Morong Map 73
Flowers May-July.

Around ponds, sloughs, and margins of oxbow lakes in river valleys, usually growing in more quiet

waters than the next species. Scattered over the state, but absent from most of the Ozark section.

Ranges from Quebec to Minnesota, south to Virginia, Kentucky, Illinois, Missouri, and Oklahoma.

In this species the rhizome is lacking or inconspicuous.

- 3. *Sparganium americanum* Nutt. Map 74
Flowers May-early September, mostly June-July.

Common in cold-water springs and spring branches throughout the Ozark region north to St. Louis, Franklin, Maries, Miller, Morgan, Polk, and Newton counties, and locally in Jackson County.

Ranges from Newfoundland and Ontario to Minnesota and North Dakota, south to Florida, Alabama, and Missouri.

This is usually the largest aquatic plant found in and along the waters of the Ozark springs. The plants often remain submerged in a vegetative state for long periods of time in the constantly flowing spring water.

Order **NAJADALES**Fam. **NAJADACEAE** (Pondweed Family)

(Zosteraceae in large part [G]; Potamogetonaceae)

- a. Some or all of the leaves over 5 mm. broad, broadly oblong or ovate 1. **POTAMOGETON**
- a. All the leaves thread-like or very narrow, less than 3 mm. broad b
- b. Leaves alternate c
- c. Plants growing in salty-sulphur water; each flower and fruit on an obvious stalk; leaf widening at base into an enlarged sheath 2. **RUPPIA**
- c. Plants growing in fresh water; flowers and fruits closely clustered or arranged in a head or spike, the individual flowers without stalks (sessile); submerged leaves not noticeably widened at base into a sheath, or, if furnished with a stipule, the base not noticeably widened 1. **POTAMOGETON**
- b. Leaves opposite d
- d. Leaves slightly or conspicuously widened at the base with a basal sheath, the leaf-margins or broadened base with tiny teeth (use lens); flowers or fruits solitary in the leaf-axils 4. **NAJAS**
- d. Leaves with about the same width at the base as at other parts of the leaf, the leaf-margins without teeth (use lens); flowers or fruits 2-4 3. **ZANNICHELLIA**

1. **Potamogeton** L. Pondweed

A few of the species in this genus possess starchy and edible fleshy rootstocks.

- a. Margins of all the leaves finely and definitely toothed 2. **P. CRISPUS**
- a. Margins of leaves either entire (smooth-edged) or teeth very minute and inconspicuous b
- b. Leaves all submerged c
- c. Submerged leaves with sides curved, not straight and parallel d
- d. Submerged leaves 27-37-nerved, arched, curved, or folded with a strongly wavy surface; margins of submerged leaves without any minute teeth (use lens); floating leaves with usually 30-51 nerves 7. **P. AMPLIFOLIUS**
- d. Submerged leaves 7-19-nerved, flat, not arched, nor curved, nor folded, nor with a strongly wavy surface; margins of submerged leaves with tiny 1-celled teeth (use lens); floating leaves with usually 7-29 nerves 9. **P. NODOSUS**
- c. Submerged leaves thread-like or ribbon-like with straight or parallel sides, 0.5-8 mm. wide, usually 0.5-3 mm. wide e
- e. Submerged leaves 2-8 mm. wide, with many rows of long cells joining in a network 1-2 mm. wide or wider on each side of the midrib (hold leaves to light); stems flat 6. **P. EPIHYDRUS** var. **NUTTALLII**
- e. Submerged leaves 0.5-3 mm. wide, without or with 1-3 inconspicuous rows of enlarged cells forming a network less than 1 mm. wide on each side of the midrib; stems cylindrical (round when cut cross-wise) f
- f. Stipules united with the base of the leaf, forming a sheath g
- g. Stem dichotomously forking; tree-like in aspect; flower spikes elongated, several times longer than broad, 1.5-5 cm. long, with interrupted whorls of flowers; main stalk (peduncle) supporting flower-spike elongated, 3-20 cm. long; fruits 3.5-4 mm. long 1. **P. PECTINATUS**
- g. Stem freely branching, but not dichotomously forking or tree-like; flower spikes oblong to almost globular, barely or somewhat longer than broad, 0.5-2 cm. long, the flowers clustered, not in interrupted whorls; main stalk (peduncle) supporting flower-spike very short or at most 1.5 cm. long; fruits 1-1.8 mm. long 5. **P. DIVERSIFOLIUS**
- f. Stipules not united with, and free from the base of the leaf h
- h. Leaves with 2 minute glands at their base; main stalk (peduncle) supporting flower-spike thread-like, 1.5-9 cm. long; plants usually in ponds and quiet water of slow streams; main stems long and much-branched 4. **P. PUSILLUS**
- h. Leaves without any basal glands; main stalk (peduncle) supporting flower-spike

Plate no. 10. 1. *Sparganium androcladum*, $\times \frac{2}{7}$; a. Female flower-head, $\times \frac{2}{7}$. 2. *Sparganium americanum*, $\times \frac{2}{7}$; a. Single female flower, $\times \frac{1}{3}$; Details from Small, The New York Botanical Garden. 3. *Potamogeton pulcher*, $\times \frac{2}{7}$. 4. *Potamogeton amplifolius*, $\times \frac{2}{7}$; a. Shallow water type; b. Deep water type. 5. *Potamogeton nodosus*, $\times \frac{2}{7}$; a. Submerged type in swift-flowing water; b. Type with floating and submerged leaves.

PLATE NO. 10

76 *Potamogeton crispus* (Curly Muck-weed)77 • *Potamogeton foliosus* var. *foliosus*
77 □ *Potamogeton foliosus* var. *macellus*78 • *Potamogeton pusillus* var. *pusillus*
78 □ *Potamogeton pusillus* var. *minor*

- slightly thickened upward, mostly 0.3–1 cm. (rarely more) long; plants usually in running water of streams and spring branches, occasionally in ponds; main stems nearly simple to loosely branched. 3. *P. FOLIOSUS*
- b. Some leaves floating with an oblong, elliptical, or ovate shape, much thicker than the submerged leaves, or not resembling them i
- i. Submerged leaves 0.5–8 mm. wide, ribbon-like with straight or parallel sides j
- j. Submerged leaves 0.5–1.5 mm. wide; no rows of enlarged cells forming loose network on either side of midrib; stems cylindrical 5. *P. DIVERSIFOLIUS*
- j. Submerged leaves 2–8 mm. wide; many rows of long cells joining in a network, 1–2 mm. wide or wider on each side of midrib (hold leaves to light); stem compressed, flat 6. *P. EPIHYDRUS* var. *NUTTALLII*
- i. Submerged leaves 4–50 mm. wide, with curved, not parallel sides k
- k. Main stem and petiole (stalk of leaf) dark-spotted; at least some of the floating leaves rather cordate at base (heart-shaped); plants of sink-hole ponds of the Ozarks. 8. *P. PULCHER*
- k. No dark spots on stem or leaf-stalk; floating leaves narrowed or rounded, but not heart-shaped at base; plants of slow or rapid streams, spring-fed branches, ponds, and sloughs l
- l. Submerged leaves (25) 27–37 (–39)-nerved, arched, curved, or folded with a *strongly wavy surface*; margins of submerged leaves without any minute teeth (use lens); floating leaves with usually 30–51 (–55) nerves 7. *P. AMPLIFOLIUS*
- l. Submerged leaves 7–19-nerved, *flat*, not arched, curved or folded, nor with a strongly wavy surface; margins of submerged leaves with tiny 1-celled teeth (use lens); floating leaves with usually 7–29 nerves m
- m. Submerged leaves 4–20 mm. wide; floating leaves usually lanceolate-oblong or narrowly elliptical; plants of larger rivers and streams 9. *P. NODOSUS*
- m. Submerged leaves 20–50 mm. wide; floating leaves usually ovate, broadly oblong, or oval; plants of cool spring-fed sloughs and branches. 10. *P. ILLINOENSIS*
1. ***Potamogeton pectinatus* L.**
Fennel-leaved Pondweed Map 75
Flowers May–September.
In fresh- or salt-water lakes fed by springs, and in streams, scattered along the Mississippi, Missouri, Current, and Gasconade rivers and tributaries, and in artificial and natural ponds and sloughs.
Ranges from Newfoundland to Alaska, south to Florida, West Virginia, Great Lake States, Missouri, Texas, and California; also in Mexico, South America, Eurasia, and Africa.
2. ***Potamogeton crispus* L.**
Curly Muck-weed Map 76
Flowers May–September.
Lakes, ponds, and sloughs fed by spring water.
Known only from Crawford and Newton counties.
An introduced European species which has spread from Quebec and Ontario to Minnesota, south to Virginia and Missouri; also in California.
3. ***Potamogeton foliosus* Raf.** Map 77
Flowers from June 1 to October, but mainly in July and August.

PLATE NO. II

79 *Potamogeton diversifolius*80 *Potamogeton epihydrus* var. *Nuttallii*81 *Potamogeton amplifolius*

Two scarcely separable varieties have been recognized, but completely intergrade:

Largest leaves 3–5-nerved, 1.4–2.7 mm. wide; 1–3 rows of enlarged cells on each side of and at the base of the midnerve; stipules 7–18 mm. long; beak of fruit broad at base, 0.2–0.4 mm. long; leaves deep green to bronze . . . *P. FOLIOSUS*

var. *FOLIOSUS*

Largest leaves 1–3-nerved, 0.3–1.5 mm. wide; no enlarged cells or 1 row of them on each side of midnerve below the middle; stipules 3–11 mm. long; beak of fruit slender, 0.3–0.8 mm. long; leaves bright green . . . *P. FOLIOSUS* var. *MACELLUS*

Both varieties inhabit springs, or mostly spring-fed streams, although occasionally they occur in ponds and lakes. They are found usually throughout the Ozark region, extending north to Monroe, Macon, Chariton, and Platte counties.

Potamogeton foliosus var. *foliosus* occurs from New York to Washington south to the West Indies and Mexico; var. *macellus* Fern. extends from Nova Scotia and Quebec to British Columbia, south to Florida, Kentucky, Missouri, Kansas, New Mexico, and California.

4. *Potamogeton pusillus* L. Map 78

Potamogeton panormitanus Bivona-Bernardi var. *major* G. Fischer [P & S]

Potamogeton panormitanus var. *minor* Biv. [P & S]

Flowers about June 1 to October.

Two forms, sometimes recognized, occur in Missouri:

Main leaves 1–3 mm. wide *P. PUSILLUS* var. *PUSILLUS*
Main leaves 0.3–1 mm. wide *P. PUSILLUS* var. *MINOR*

Both varieties are quite rare and local in Missouri, where they occur usually in slow-water of streams, sloughs, and ponds, in contrast to the faster-flowing, cooler spring-fed waters associated usually with *P. foliosus*.

Potamogeton pusillus var. *pusillus* (*P. panormitanus* var.

major) ranges from Quebec to Alberta and British Columbia, south to Virginia, Alabama, Louisiana, Texas, and Mexico; also in the West Indies and Eurasia; var. *minor* (Biv.) Fern. & Schub. (*P. panormitanus* var. *minor*) has nearly the same range.

5. *Potamogeton diversifolius* Raf. Map 79

Flowers late May–October.

Common in warm waters of both natural and artificial ponds, and sloughs or quiet waters of slow streams in most of central and southern Missouri, and locally north in Scotland County.

Ranges from Mexico, Texas, and Florida north to New Jersey, Pennsylvania, Wisconsin, Montana, and Oregon.

This species is very common in artificial lakes and ponds.

6. *Potamogeton epihydrus* Raf. var. *Nuttallii* (C. & S.) Fern. Map 80

Flowers usually July through September.

In Missouri known only from a sink-hole pond in the Ozarks in Reynolds County (Lily Pond, 7 miles southeast of Centerville, September 5, 1949, *Steyermark 69232*).

This variety ranges from Newfoundland to Manitoba, south to Virginia, Georgia, Tennessee, and Missouri; and from Alaska to Colorado and California.

This northern plant is one of the isolated relicts known from sink-hole ponds in Missouri, growing close to another sink-hole pond where *Decodon verticillatus*, also an isolated relict in Missouri, occurs.

7. *Potamogeton amplifolius* Tuckerm. Map 81

Flowers about June 1 to October.

Usually occurring in springs and spring-fed branches, sloughs, and lakes in the Ozark region west to

Ozark, Dallas, and Camden counties, north to Morgan, Pulaski, and Washington counties.

Ranges from Newfoundland to North Dakota, south to Virginia, Alabama, Arkansas, and Oklahoma; and from Montana to British Columbia south to Idaho and California.

8. **Potamogeton pulcher** Tuckerm.

Spotted Pondweed

Map 82

Flowers about June 1 to October.

This species is characteristic of sink-hole ponds in the Ozark upland in Missouri, and is occasionally found in streams. In drouth years when the sink-ponds may become nearly dry, the stems of this species become shorter and only the upper broad leaves of the floating type are evident. The species has been collected as far north in Missouri as St. Louis and Franklin counties, but the present known stations occur farther south in the Ozarks.

Ranges from Florida to Texas north to Nova Scotia, New York, Pennsylvania, Ohio, Indiana, Illinois, Minnesota, and Oklahoma.

9. **Potamogeton nodosus** Poir.

Map 83

Potamogeton americanus Cham. & Schl. [P & S]

Potamogeton rotundatus Hagstr. [P & S, Steyererm.]

Flowers late May–October.

Common in the major Ozark streams, in sloughs, and ponds north to Pike, Macon, and Platte counties.

Ranges from Alabama, Texas, and Mexico, north to New Brunswick, Ontario, Michigan, Minnesota, South Dakota, Montana, and British Columbia.

This species has much more elongated and narrower floating leaves than any of the other large-leaved species of pondweed in Missouri. It is the most common large-leaved species encountered in the Ozark streams, but avoids the colder water of the springs and spring branches.

10. **Potamogeton illinoensis** Morong.

Shining Pondweed

Map 84

Potamogeton lucens of Am. auth., not L. [P & S, Steyererm.]

Flowers about June 1 to October.

This species often occurs with submerged leaves

Plate no. 12. 1. *Potamogeton diversifolius*, $\times \frac{2}{5}$. 2. *Potamogeton epihydrus* var. *Nuttallii*, $\times \frac{2}{5}$; a. Fruit, vertical section, showing embryo, $\times \frac{2}{5}$; b. Submerged leaves, $\times \frac{2}{5}$; c. Floating leaves and inflorescences, $\times \frac{2}{5}$; d. Fruit, $\times \frac{2}{5}$; After Britton and Brown, The New York Botanical Garden. 3. *Ruppia maritima* var. *rostrata*, $\times 1$; a. Single fruit, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden. 4. *Zannichellia palustris* var. *major*, $\times \frac{2}{5}$; a. Single fruit, $\times 4$; Details from Small, The New York Botanical Garden.

82 *Potamogeton pulcher* (Spotted Pondweed)83 *Potamogeton nodosus*84 • *Potamogeton illinoensis* (Shining Pondweed)
84 † *Potamogeton illinoensis* X *Potamogeton nodosus*

only. It is a characteristic large-leaved pondweed of the cool waters of springs, and spring-fed ponds and streams of the Ozark region, occurring west to Ozark, Wright, Laclede, and Morgan counties, and north to Maries, Crawford, and Perry counties.

Ranges from Quebec to British Columbia south to Florida, Ohio, Indiana, Illinois, Arkansas,

Texas, Nebraska, Colorado, Utah, and California.

10a. *Potamogeton illinoensis* × *P. nodosus*

Map 84

This hybrid, cited by Ogden (Rh. 45: 185-86, 1943) has been collected from Cooley Lake, Clay County, by *Metcalf 1055* (U.S. Nat. Herb.).

2. *Ruppia* L. Ditch Grass

Ruppia maritima L. var. *rostrata* Agardh

Map 85

Flowers mostly July-October.

Known in Missouri from two stations: (1) Henry County and (2) Ralls County. The Ralls County record is from a lake formed by a salt-sulphur spring

at Spalding, September 3, 1937, *Steyermark 25691*.

The var. *rostrata* ranges from Newfoundland to Quebec south to Florida, and from scattered stations inland from New York to the Pacific, south to Missouri, Oklahoma, and California; also in Mexico, the West Indies, South America, Eurasia, and Africa.

3. *Zannichellia* L. Horned Pondweed

Zannichellia palustris var. *major* (Boenn.)

W. D. J. Koch

Map 86

Zannichellia palustris L. [BB, P & S]

Flowers late May-October.

In fresh water springs, salt and sulphur springs, marshes, ponds, and along shallow and back-water sloughs of streams. It is scattered throughout Missouri, but is commonest in the Ozark streams and spring water, and in salt-sulphur spring waters of central Missouri.

Zannichellia palustris var. *palustris* is widespread from Quebec to Alaska south to West Virginia, Tennessee, Texas, and Mexico, also in South America, Eurasia, and Africa; the var. *major* extends south to Florida. Since Missouri specimens have the fruits commonly dentate and pedicelled with a body 3-3.6 mm. long and a beak 1-2 mm. long they are assigned to var. *major*, as interpreted by Fernald in the eighth edition of *Gray's Manual*.

4. *Najas* L. Naiad

a. Base of leaf abruptly widened into coarsely toothed or jagged lobes; leaves mostly 0.1-0.3 mm. wide

1. *N. GRACILLIMA*

a. Base of leaf gradually widened, not lobed above base and only finely toothed along margin; leaves mostly (0.4) 0.5-1 mm. wide

b. Plants of artificial ponds, very rare; leaves tapering to a long fine point; style 0.9 mm. or more long; seed finely and inconspicuously marked with 30-40 rows of hexagonal pits across the middle, usually shining

2. *N. FLEXILIS*

b. Plants of streams, sloughs, and marshes, common; style 0.6 mm. or less long; tip of leaves rounded to short-pointed; seed dull, coarsely and deeply pitted, with 10-20 rows of rectangular pits across the middle.

3. *N. GUADALUPENSIS*

85 *Ruppia maritima* var. *rostrata* (Ditch Grass)

86 *Zannichellia palustris* var. *major* (Horned Pondweed)

87 *Najas gracillima* (Naiad)

1. ***Najas gracillima*** (A. Br.) Magnus Map 87
Flowers mostly July–September.

Known from only two upland sink-hole ponds in the Ozarks in Shannon and Texas counties (3½ mi. south of Licking, July 15, 1937, *Steyermark 23277*), and introduced in an artificial pond at Moberly, Audrain County (Crystal Lake, Aug. 21, 1939, *J. R. Hurt 50*).

Ranges from Maine to Minnesota, south to Virginia, Kentucky, and Missouri.

This species has more filiform leaves (0.1–0.3 mm. wide), and the areolae (honeycombed network of cells) on the surface of the seeds are slightly more elongate than in the other species of Missouri.

2. ***Najas flexilis*** (Willd.) Rostk. Map 88
Flowers mainly July–September.

This is collected for Missouri on the basis of a fruiting collection from ‘More’s Lake, Columbia’ in Boone County, collected by *Francis Daniels* on July 21, 1903, deposited in the herbarium of the University of Missouri. ‘More’s Lake’ is actually the same as Moore’s Lake, indicated on government topographical maps, and is the one by the power and light company plant just north of highway 40 in Columbia. The elongate style and stigma, together with the yellowish pericarp closely investing the obscurely reticulate fruit

with 30–40 rows of minute subhexagonal areolae, bushy-branching habit, recurved, narrowly pointed leaves, are the chief characters relied upon in the present identification. Two other sheets in the University of Missouri Herbarium, labeled ‘*Najas flexilis*,’ were similarly collected by Daniels from ‘More’s Lake’ on July 21, 1903, but lack mature fruit. The immature fruits of these two sheets are purplish with rather deeply marked areolae, more characteristic of *N. guadalupensis*.

Ranges from Newfoundland and Quebec to Minnesota, south to Virginia, Ohio, Indiana, Illinois, Missouri, and Iowa, and from Alberta to British Columbia south to Oregon; also in northern Europe.

3. ***Najas guadalupensis*** (Spreng.) Magnus Map 89
Flowers mostly July–October.

Common in shallow margins of streams, sloughs, and marshes in southern and central Missouri, commoner in the Ozarks, and north locally to Macon County.

Ranges from tropical America north to Massachusetts, New York, Pennsylvania, Ohio, Michigan, Minnesota, South Dakota, Idaho, and Oregon.

Order **ALISMALES**

Fam. **ALISMACEAE** (Water Plantain Family)
(*Alismataceae* [G])

- a. Each flower with 6 stamens; pistils in one ring on a small flat receptacle 1. ALISMA
- a. Some of the flowers with 6–20 or more stamens; pistils in several series in a head on enlarged greenish-white receptacle b
 - b. All flowers perfect (with both stamens and pistils in the same flower); individual mature seed-like fruits (achenes) plump with ribs or ridges, not flattened or winged; in addition to the 3 minute or leaf-like bracts at each joint where the flower-stalks originate, there are additional papery or minute outgrowths (bracteoles) 2. ECHINODORUS
 - b. Some flowers with either stamens or pistils, but not both on the same flower; individual mature seed-like fruits (achenes) flattened or winged; only the 3 papery or leaf-like bracts present at each joint where the flower-stalks originate 3. SAGITTARIA

88 *Najas flexilis* (Naiad)89 *Najas guadalupensis* (Naiad)90 *Alisma Plantago-aquatica* (combined range of varieties shown) (Water Plantain)1. *Alisma* L. Water Plantain***Alisma Plantago-aquatica* L.** Water Plantain
Map 90

Flowers late May–September.

Generally found along muddy borders of ponds, sloughs, slow streams, marshes, and temporary pools throughout Missouri.

The genus *Alisma* has been most recently studied by Dr. A. J. Hendricks, and according to him (Am. Midl. Nat. 58: 470–93. 1957), the Missouri material is divided as follows into three varieties of *A. Plantago-aquatica*:

- a. Diameter of mature fruiting portion 3.5 mm. or less; fruits mostly with 1 groove. c. **A. PLANTAGO-AQUATICA var. PARVIFLORUM**
- a. Diameter of mature fruiting portion 4–4.5 mm. or more; fruits either with 1 or 2 grooves. **b**
- b. Diameter of mature fruiting portion about 4 mm.; petals white. **b. A. PLANTAGO-AQUATICA var. AMERICANUM**
- b. Diameter of mature fruiting portion 4.5 mm. or more; petals white to purple-tipped
- a. **A. PLANTAGO-AQUATICA var. PLANTAGO-AQUATICA**

a. *Alisma Plantago-aquatica* var. *Plantago-aquatica*

Alisma Plantago-aquatica var. *Michaletii* (Aschers. & Graebn.) Buchenau

Hendricks credits this variety to Missouri on the basis of the specimen of *Palmer 3786* from Melugen, Lawrence County.

According to Hendricks, the range extends into Europe and Asia, Africa, South America, and North

America.

b. *Alisma Plantago-aquatica* var. *americanum*

J. A. Schultes & Schult.

Alisma triviale Pursh [G]

Hendricks cites Missouri material from Butler Co. (*Stull 735*) and Maries Co. (*Steyermark 27615*).

The range is given as Asia and North America.

c. *Alisma Plantago-aquatica* var. *parviflorum*
(Pursh) Torr.

Alisma subcordatum Raf. [P & S, G in part, BB in part]

Hendricks cites Missouri material from Livingston (*Sparling 1049B*), Laclede (*Steyermark 13908*), and Howell (Willow Springs, *Bush*) counties.

The range is indicated as the southern United States north to Vermont, Pennsylvania, Ohio, Indiana, Illinois, Missouri, Kansas, and Nebraska.

Typical *A. Plantago-aquatica* var. *Plantago-aquatica* is apparently the widespread variety which Hendricks treats under var. *Michaletii*.

The present author has not yet had an opportunity to evaluate Dr. Hendricks' treatment in the field nor to apply it to all the Missouri material which has been collected. Accordingly, the varieties presented here are being accepted, subject to future studies, and on the distribution map go only the combined range of the three varieties is shown.

Plants belonging to this group of varieties are sometimes dug in autumn or spring when the roots and solid base of the stem are well filled with starch, and then cooked as a starchy vegetable.

Plate no. 13. 1. *Najas gracillima*, $\times \frac{2}{5}$; a. Base of a single leaf, $\times \frac{2}{5}$; b. Cluster of flowers and portion of surrounding leaf-bases, $\times \frac{1}{5}$; Details from Small, The New York Botanical Garden. 2. *Najas guadalupensis*, $\times \frac{2}{5}$; a. Single female flower, $\times 12$; b. Single leaf, $\times \frac{3}{5}$. 3. *Echinodorus cordifolius*; a. Fruit, $\times \frac{4}{5}$; b. Leaf, $\times \frac{2}{5}$; c. Flower, $\times \frac{3}{5}$; Details from Small, The New York Botanical Garden.

PLATE NO. 13

91 *Echinodorus cordifolius* (Burhead)92 *Echinodorus Berteroi* var. *lanceolatus* (Burhead)93 *Echinodorus tenellus* var. *parvulus*

2. *Echinodorus* Rich. Burhead

The present treatment is adapted from Dr. Fassett's recent revision of this genus (Rh. 57: 133-56; 174-88; 202-12. 1955).

- a. Plants 1.5-10 cm. tall; leaves mostly narrow, linear-lanceolate to narrowly elliptic, tapering at each end, up to 12 mm. wide; stamens 6 or 9; pistils 20 or fewer in a loose head; fruits without beaks 3. *E. TENELLUS* var. *PARVULUS*
- a. Plants usually 10-60 cm. tall; leaves mostly ovate or broadly lanceolate, usually rounded or heart-shaped at base, mostly 15-150 mm. wide, but in dwarfed plants the leaves are narrowed to 5-10 mm. wide and are lanceolate; stamens 9-30; fruits with beaks b
- b. Main flower-stem (scape) upright, mostly branched; sepals with smooth veins; fruits with beaks 0.5-0.8 (-1) mm. long; transparent lines on leaves (use lens) mostly less than 1 mm. apart and often several mm. long 2. *E. BERTEROI* var. *LANCEOLATUS*
- b. Main flower-stem (scape) eventually lying on or touching the ground (prostrate or procumbent); sepals with ridges covered with tiny projections (papillae); fruits with beaks 0.2-0.8 mm. long; transparent lines on leaves mostly 1 mm. or more apart and rarely more than 1 mm. long. 1. *E. CORDIFOLIUS*

1. ***Echinodorus cordifolius*** (L.) Griseb. Map 91
Echinodorus radicans (Nutt.) Engelm. [BB, P & S]
Flowers July-September.

The main occurrence of this species is in the swampy lowland section of southeastern Missouri, along muddy wet shores of oxbow lakes of the Mississippi River north to Pike County, and of the Osage and Marmaton rivers in Vernon and Bates counties.

Ranges from Texas and Florida to the District of Columbia, north along the Mississippi Valley to Tennessee, Indiana, Illinois, Missouri, and west to Kansas and Oklahoma.

2. ***Echinodorus Berteroi*** (Spreng.) Fassett
var. *lanceolatus* (Engelm.) Fassett Map 92
Echinodorus rostratus (Nutt.) Engelm. f. *lanceolatus* (Engelm.) Fern. [G]
Echinodorus cordifolius var. *lanceolatus* (Engelm.) Mack. & Bush [P & S]
Echinodorus cordifolius [BB]

Flowers July-September.

Occurring in low wet woods in the southeastern lowland section, and along sloughs and margins of oxbow lakes and backwaters of the Missouri and Mississippi rivers and their tributaries.

Ranges from Ohio, Illinois, Missouri, Iowa, and South Dakota, south to Arkansas and Texas, and also in California.

The submerged leaves of this and the preceding species often are used as decorative aquatic plants in tropical fish aquaria, sold under the name of 'Poor Man's Lace Plant.'

3. ***Echinodorus tenellus*** (Mart.) Buch.
var. *parvulus* (Engelm.) Fassett Map 93
Echinodorus parvulus Engelm. [BB]
Echinodorus tenellus (Mart.) Buch. [G, P & S]
Flowers August-September.
Originally found in 1845 in St. Louis County along margins of ponds in the hills north, northwest, and

Plate no. 14. 1. *Sagittaria rigida* f. *rigida*, $\times \frac{2}{5}$; a, b. Two types of leaves found in *Sagittaria rigida* f. *elliptica*, $\times \frac{2}{5}$. 2. *Echinodorus Berteroi* var. *lanceolatus*, $\times \frac{2}{5}$; After Gleason, details from Small, The New York Botanical Garden. 3. *Echinodorus tenellus* var. *parvulus*, $\times 1\frac{1}{5}$; a. Flower, $\times 2\frac{4}{5}$; b. Fruit, $\times 4$; After Britton and Brown, The New York Botanical Garden. 4. *Sagittaria montevidensis* subsp. *calycina*, $\times \frac{2}{5}$; After Gleason, details from Small, The New York Botanical Garden.

PLATE NO. 14

west of St. Louis by Dr. Engelmann. These ponds have since become destroyed. The only known Missouri station is from an upland sink-hole pond in the southern Ozarks in Howell County (Adobesee Pond, T22N, R7W, southeast sect. 36, 9 mi. southeast of West Plains, Sept. 4, 1949, *Steyermark 69124a*).

Dr. Fassett considers this Howell County station in the heart of the Ozarks as the possible ancestral area from which the North American variety of *Echinodorus tenellus* migrated to the younger coastal

plain, where it is now mainly found, ranging from Mexico, Texas, and Florida, north to Massachusetts, Illinois, and Missouri. Typical *E. tenellus* var. *tenellus* is limited in its distribution to South America.

The submerged leaves of this variety and of other tropical American varieties make handsome aquatic plants for tropical fish tanks, and enter the trade under various common names, such as 'Dwarf Cellophane Plant.'

3. *Sagittaria* L. Arrowhead (including *Lophotocarpus* Th. Durand [G])

In a recent revision of this genus (Mem. N.Y. Bot. Gard. 9: 179-233. 1955), Dr. Bogin has united the genus *Lophotocarpus* with *Sagittaria*. His work, in the main, is followed in the present treatment.

The tubers produced at the ends of the rhizomes in *Sagittaria* are sometimes confused with the roots of *Peltandra* and *Pontederia*. For purposes of identification, it may be pointed out here that *Peltandra* has a deep, vertical, stout root, *Sagittaria* does not have a strong deep rootstock, but sends out root-fibers from the base of the leaf-tufts, and *Pontederia* has a long creeping rhizome.

The submerged bladeless ribbon-like leaves of a number of species of the genus are commonly sold for ornamenting tropical fish tanks.

- a. Sepals large and conspicuous, appressed to and surrounding the mature fruit, nearly orbicular; lower flowers perfect (with both stamens and pistils in the same flower); fruiting pedicels very thick, mostly 2-5 cm. long 1. *S. MONTEVIDENSIS*
- a. Sepals not large and conspicuous, spreading or reflexed (turned down), not surrounding the fruit at maturity nor nearly orbicular; lower whorls (circles) of flowers either all pistillate (female) or all staminate (male); fruiting (pistillate) pedicels not conspicuously thick. b
- b. Lowest (pistillate) heads of flowers without stalks (sessile) 2. *S. RIGIDA*
- b. All heads of flowers with stalks (pedicels) c
- c. Leaves not arrowhead-shaped nor with tail-like lobes at base d
- d. Filaments glabrous (without hairs or scales); leaf-blades pinnately-nerved (main side nerves joining the midnerve at points one above the other, feather-like); the 3 papery or leaf-like bracts (at base of each whorl of flower-stalks) nearly separate, lanceolate, long-pointed, 9-15 mm. long 4. *S. AMBIGUA*
- d. Filaments minutely hairy or roughened (use lens); leaf-blades palmately-nerved (main nerves arising from the base); the 3 papery bracts (at base of each whorl of flowers), united at their base, ovate, 3-8 mm. long 3. *S. GRAMINEA*
- c. Leaves arrowhead-shaped or with tail-like lobes at base e
- e. The 3 papery or thin bracts at base of each whorl of pistillate (female) flower- or fruit-stalks rounded, blunt, or only slightly pointed at tip, 1 cm. or less long; main flower-stem (scape) round in cross-section, scarcely angled; beak of mature fruit horizontal 6. *S. LATIFOLIA*
- e. The 3 papery or firm leaf-like bracts at base of each whorl of pistillate (female) flower- or fruit-stalks long-pointed at tip, 1.5-4 cm. long; main flower-stem (scape) angled; beak of mature fruit erect to ascending 5. *S. ENGELMANNIANA* subsp. *BREVIROSTRA*

- 1. *Sagittaria montevidensis* Cham. & Schl.,
subsp. *calycina* (Engelm.) Bogin Map 94
Lophotocarpus calycinus (Engelm.) J. G. Sm. [G,
P & S]

Sagittaria montevidensis [of BB]

Flowers late June-September.

Inhabiting shallow water and muddy margins of sloughs, ponds, and sluggish streams, where found

nearly throughout Missouri; absent from many counties of northern Missouri, but of expected frequent occurrence with more intensive collecting there.

Ranges from Ohio and Michigan to Minnesota and South Dakota, south to Virginia, Alabama, Louisiana, and Texas.

Several forms, originally cited under *Lophotocarpus calycinus*, have been noted as occurring in Missouri:

94 *Sagittaria montevidensis* subsp. *calycina*95 • *Sagittaria rigida* f. *rigida* (Stiff Arrowhead)
95 x *Sagittaria rigida* f. *elliptica*
95 □ *Sagittaria rigida* f. *fluitans*96 • *Sagittaria graminea* var. *graminea*
96 □ *Sagittaria graminea* var. *platyphylla*

Lophotocarpus calycinus f. *depauperatus* (Engelm.) Fern., with unlobed or barely auricled narrowly elliptic to spatulate leaves, known from Jefferson, Reynolds, Christian, and Newton counties; f. *maximus* (Engelm.) Fern., with lobed leaves 3 dm. wide and much wider than long, known from Christian County (Palmer 64429) and Moniteau County (Steyermark 76596); and f. *fluitans* (Engelm.) Steyermark from Ste. Genevieve County (Steyermark 21097). All of these are considered as of no taxonomic value by Dr. Bogin, and are placed as direct synonyms under *Sagittaria montevidensis* subsp. *calycinus*.

2. ***Sagittaria rigida*** Pursh Stiff Arrowhead Map 95
Flowers late May–October.

The following leaf forms occur in Missouri:

- a. Leaves without blades, only the leaf-stalks present, 5–10 mm. wide. 2c. *S. RIGIDA* f. *FLUITANS*
- a. Leaves with definitely developed leaf-blades. b
- b. Leaf-blade scarcely wider than the leaf-stalk (petiole), linear-lanceolate to oblanceolate, unlobed, tapering at each end
2a. *S. RIGIDA* f. *RIGIDA*
- b. Leaf-blades definitely wider than the leaf-stalk (petiole), broadly lanceolate, elliptical, or oval, lobed, unlobed, or lobed with 1 or 2 short basal lobes, gradually curving or rounded at the base 2b. *S. RIGIDA* f. *ELLIPTICA*

- 2a. ***Sagittaria rigida*** Pursh f. *rigida* Map 95
Sagittaria heterophylla Pursh [P & S]
Sagittaria heterophylla var. *angustifolia* Engelm. [P & S]
Sagittaria rigida Pursh [G]
Sagittaria rigida in part [BB]

- 2b. ***Sagittaria rigida*** f. *elliptica* (Engelm.) Fern. Map 95
Sagittaria heterophylla var. *elliptica* Engelm. [P & S]
Sagittaria rigida in part [BB]

2c. ***Sagittaria rigida*** f. *fluitans* (Engelm.) Fern. Map 95

Sagittaria rigida f. *rigida* and the other forms occur throughout Missouri, where they are found mostly along the margins of natural upland sink-hole ponds, oxbow ponds of river valleys, artificial ponds, and along sloughs. Commonest in the Ozark region.

The whole series of variations range from Quebec to Maine and Minnesota, south to Virginia, Kentucky, Tennessee, Missouri, and Nebraska; also introduced in Europe.

Some authors of aquatic plants (Fassett, Fernald) have maintained the above as forms deserving recognition. Other botanists, such as Gleason, believe that the plant varies according to the habitat, while Muenscher states that all forms of leaf variation may originate from the same plant. My own experience indicates that some leaf variations are constant and characteristic of some places or occur in definite colonies. I have not found all types of leaf variations originating from the same plant, as indicated by Muenscher.

3. ***Sagittaria graminea*** Michx. Map 96

The following two varieties, as treated by Dr. Bogin, may be recognized in Missouri:

Fruiting heads 4–8 mm. in diameter; stalks (pedicels) of pistillate (female) flowers and of fruits slender, horizontally or upwardly spreading; petioles (leaf-stems) not noticeably 3-angled; leaves mostly with 3–5 main nerves 3a. *S. GRAMINEA* var. *GRAMINEA*

Fruiting heads 9–14 mm. in diameter; stalks (pedicels) of pistillate (female) flowers and of fruits thickish, the fruiting pedicels slightly to noticeably downwardly curving; petioles (leaf-stems) noticeably 3-angled; leaves mostly with 5–11 main nerves 3b. *S. GRAMINEA* var. *PLATYPHYLLA*

97 *Sagittaria ambigua*98 *Sagittaria Engelmanniana* subsp. *brevirostra*

99 • *Sagittaria latifolia* var. *latifolia* f. *latifolia* (Common Arrowhead)
 99 x *Sagittaria latifolia* var. *latifolia* f. *hastata*
 99 † *Sagittaria latifolia* var. *latifolia* f. *gracilis*
 99 □ *Sagittaria latifolia* var. *obtusata*

3a. ***Sagittaria graminea* Michx. var. *graminea***

Michx.

Map 96

Sagittaria graminea Michx. [G, P & S, BB]

Flowers late May–September.

This occurs along the margins of ponds, sloughs, and in ditches, occurring mostly in southern and central Missouri north to St. Louis, Carroll, and Jackson counties.

Ranges from Newfoundland to Ontario, south to Virginia, Florida, Ohio, Indiana, Illinois, Missouri, and Texas.

Plants are frequently encountered with slender petioles lacking leaf-blades, or with only submerged, thin, linear-lanceolate, bladeless phyllodia.

3b. ***Sagittaria graminea* var. *platyphylla***

Engelm.

Map 96

Sagittaria platyphylla (Engelm.) J. G. Sm. [G, P & S, Steyer.]

Sagittaria graminea [of BB]

Flowers late May–August.

Borders of ponds, sloughs, and in swampy ground, in the lowlands of southeastern Missouri, and introduced in a pond in Boone County (Dunn 12855).

Ranges from Missouri and Kansas to Alabama, Louisiana, and Texas.

4. ***Sagittaria ambigua* J. G. Sm.**

Map 97

Flowers June 2–July.

Borders of ponds, sloughs, and ditches of southwestern Missouri.

Ranges from southwestern Missouri to Kansas and Oklahoma.

5. ***Sagittaria Engelmanniana* subsp. *brevirostra***

(Mack. & Bush) Bogin

Map 98

Sagittaria brevirostra Mack. & Bush [G, P & S]

Sagittaria cuneata Sheldon [BB]

Sagittaria longirostra of P & S, not (Micheli) J. G. Sm.

Flowers June–September.

Common throughout Missouri in shallow water and muddy borders of sloughs, ponds, and sluggish streams.

Ranges from Ohio and Michigan to South Dakota, south to Illinois, Missouri, Arkansas, Oklahoma, and Texas.

All the Missouri material, according to Dr. Bogin, falls within *S. Engelmanniana* subsp. *brevirostra*, and includes Missouri material previously misidentified as *S. longirostra* and *S. australis*.

Bogin places *Sagittaria australis* (J. G. Sm.) Small and *S. longirostra* J. G. Sm. of *Gray's Manual*, eighth edition, under *Sagittaria Engelmanniana* subsp. *longirostra* (Micheli) Bogin.

6. ***Sagittaria latifolia* Willd.** Duck Potato,

Common Arrowhead

Map 99

Flowers early June–October.

The following forms, which occur in Missouri, have been recognized by some workers (Fernald, Fassett, Muenscher), but are placed by Dr. Bogin in synonymy under *Sagittaria latifolia* var. *latifolia*:

Plate no. 15. 1. *Sagittaria graminea* var. *platyphylla*, $\times \frac{2}{7}$; a. Lobed type of leaf, $\times \frac{2}{7}$; b. Fruiting branch, $\times \frac{2}{7}$. 2. *Vallisneria americana*, $\times \frac{2}{7}$; a. Male flower, $\times \frac{4}{7}$; b. Female flower, $\times \frac{4}{7}$; Details from Small, The New York Botanical Garden. 3. *Sagittaria graminea* var. *graminea*, $\times \frac{2}{7}$. 4. *Sagittaria ambigua*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{2}{7}$; b. Stamen, $\times \frac{2}{7}$; After Britton and Brown, The New York Botanical Garden. 5. *Sagittaria Engelmanniana* subsp. *brevirostra*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{2}{7}$; After Britton and Brown, details from Small, The New York Botanical Garden. 6. *Sagittaria latifolia* var. *latifolia*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{5}{7}$; After Britton and Brown, The New York Botanical Garden. 7. *Anacharis Nuttallii*, $\times \frac{2}{7}$; a. Female flower, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 8. *Limnium Spongia*, $\times \frac{2}{7}$; After Gleason, details from Small, The New York Botanical Garden.

PLATE NO. 15

- a. Leaf-blades blunt (obtuse) or rounded at tip, the main part of the leaf-blade as broad as or nearly as broad as long. 6d. *S. LATIFOLIA*
var. *OBTUSA*
- a. Leaf-blades acutely pointed at tip, the main part of the leaf-blade several times longer than broad or nearly as broad as long b
- b. Basal lobes of leaf-blade triangular; main part of leaf-blade ovate or triangular-ovate, as broad as or two-thirds as broad as long. c
- 6a. *S. LATIFOLIA*
var. *LATIFOLIA* f. *LATIFOLIA*
- b. Basal lobes of leaf-blade narrower with parallel sides; main part of leaf-blade oblong-lanceolate to triangular-ovate, 0.2–25 cm. wide, 1/7–3/4 or more as broad as long c
- c. Main part of leaf-blade 1/16–1/8 as broad as long, linear-lanceolate to narrowly linear, 0.2–1.5 cm. wide
- 6c. *S. LATIFOLIA*
var. *LATIFOLIA* f. *GRACILIS*
- c. Main part of leaf-blade 1/7–2/5 as broad as long, narrowly triangular to oblong-lanceolate 6b. *S. LATIFOLIA*
var. *LATIFOLIA* f. *HASTATA*

- 6a. *Sagittaria latifolia* var. *latifolia* f. *latifolia*
Throughout Missouri. Map 99

- 6b. *Sagittaria latifolia* var. *latifolia* f. *hastata*
(Pursh) Robins. Map 99
Known from Reynolds, Lawrence, and Jasper counties.

- 6c. *Sagittaria latifolia* var. *latifolia* f. *gracilis*
(Pursh) Robins. Map 99
Known from Washington and Lawrence counties.

- 6d. *Sagittaria latifolia* var. *obtusata* (Muhl.)
Wieg. Map 99
Sagittaria latifolia f. *obtusata* (Muhl.) Rob. [P & S]
Occasionally found with var. *latifolia* in the same general range.

Sagittaria latifolia var. *latifolia* and forms, and var. *obtusata* inhabit the muddy borders of ponds, ditches, sloughs, and sluggish streams.

The species, together with its varieties and forms, ranges from Nova Scotia to British Columbia, south to Florida, California, and Mexico.

The large starchy tubers especially of this species and *S. Engelmanniana* and its subspecies are edible after baking or boiling for about half an hour. Under the name 'Wappato' the Indians of the northwestern United States ate the tubers of this and related species, while related species are cultivated for their succulence by the Chinese.

Order HYDROCHARITALES

Fam. HYDROCHARITACEAE (Frogbit Family)

- a. Leaves heart-shaped and rounded, 30–70 mm. wide 3. LIMNOBIUM
- a. Leaves ribbon-shaped, long and narrow, or short, small and linear to ovate, 0.3–20 mm. wide b
- b. Leaves long and ribbon-shaped, arising from the base of the plant 2. VALLISNERIA
- b. Leaves short, in numerous whorls (circles) of 3 or more (sometimes only 2 opposite each other) arising up and down the length of the stem 1. ANACHARIS

1. *Anacharis* Rich. Waterweed, Bassweed (*Elodea* Michx. [G])

The generic name *Elodea* was proposed for conservation, but has not been adopted.

Common species; leaves from upper half of stem 0.5–1.8 mm. wide; staminate (male) flowers sessile (without stalks); sepals of staminate flower 2 mm. long; sepals of pistillate (female) flowers 1.1–1.8 mm. long 1. A. NUTTALLII

Rare species; leaves from upper half of stem 1.2–4.5 mm. wide; staminate flowers on long thread-like peduncle (stalk); sepals of staminate flowers 3.5–5 mm. long; sepals of pistillate flowers 2.2–2.7 mm. long 2. A. CANADENSIS

1. *Anacharis Nuttallii* Planch. Map 100
Elodea Nuttallii (Planch.) St. John [G]
Anacharis occidentalis (Pursh) Victorin [P & S]
Flowers mostly July–September.
Commonly found in cool water of springs, spring

branches, and margins of streams throughout the Ozark region, and also in ponds, lakes, pools, sloughs, and on the surface of stagnant water, locally north to Platte, Carroll, Grundy, Randolph, and Lincoln counties.
Ranges from Maine to Minnesota and Oregon,

100 *Anacharis Nuttallii* (Waterweed, Baseweed)101 *Anacharis canadensis* (Waterweed, Baseweed)102 *Vallisneria americana* (Eelgrass)

south to North Carolina, Indiana, Illinois, Missouri, Kansas, and Colorado.

2. *Anacharis canadensis* (Michx.) Planch.

Map 101

Elodea canadensis Michx. [G]

Flowers July–September.

Found in cold spring water in Wayne County (Mill Spring, Aug. 26, 1899, *Trelease*; Sept. 1, 1898, *Russell*) and in Newton County (Neosho, July 15, 1893, *Bush*).

Ranges from Quebec and Saskatchewan to Washington, south to North Carolina, Alabama, Illinois, Missouri, Oklahoma, Colorado, Utah, and California.

A third species, *Anacharis densa* (Rich.) Vict., with leaves 2–3.3 cm. long and in whorls of 4 or 6, is often planted in fish tanks and pools, and spreads vegetatively. It may be expected to occur spontaneously away from cultivation. It is introduced into the United States from South America.

2. *Vallisneria* L. Eelgrass, Tapegrass, Wild Celery

Vallisneria americana Michx.

Map 102

Flowers June–September.

Found mostly in streams (Meramec, Gasconade, Black, and Current river drainage) of the Ozarks, and locally introduced north of the Missouri River in Boone County in the lake at Stephens College Country Club.

Ranges from Nova Scotia and Quebec to North Dakota, south to Florida and Texas.

This species is a favorite food of wild ducks. It and the European *V. spiralis* L. are commonly grown aquarium plants.

3. *Limnobium* Rich. Frogbit

Limnobium Spongia (Bosc) Steud.

American Frogbit

Map 103

Flowers usually June–September.

In Missouri a very rare species where known only from the southeastern lowland counties (Mississippi, Pemiscot, and Dunklin), occurring there in back-water sloughs and drainage-ditches of the Mississippi and St. Francis river drainage.

Ranges from tropical America, Florida, and Texas, north in the coastal states to New Jersey, New York

(Lake Ontario), and north in the Mississippi Valley to southern Illinois and southeastern Missouri.

This plant, with spongy coarsely cellular leaves, often purplish beneath, is generally found floating on the surface of quiet water; occasionally plants are found rooted in the soft mud. This species is found sometimes sold as an aquarium plant under the name of 'Giant Water Violet,' but it has not been very successfully grown as such.

Order GRAMINALES

Fam. GRAMINEAE (Grass Family)

This family is the most important one economically, yielding as it does the main cereal and forage crops (wheat, rice, rye, barley, oats, corn, sorghum) and sugar cane.

Flowers of this family are entirely wind-pollinated. It is fortunate that most of the grasses are relatively harmless, so far as their importance in hay fever cases. Only a small number of the species account for the occurrence of grass hay fever, the chief ones responsible, in the order of their seasonal appearance, being sweet vernal grass (*Anthoxanthum*), June grass (*Koeleria cristata*), orchard grass (*Dactylis glomerata*), which appear in May and June, timothy (*Phleum pratense*), reedtop (*Agrostis alba*), and other species of *Agrostis*, appearing in June and July. Less important grasses from the standpoint of hay fever are red fescue (*Festuca rubra*), meadow fescue (*Festuca elatior*), quack grass (*Agropyron repens*), ryegrass (*Lolium perenne*), darnel (*Lolium temulentum*), and velvet grass (*Holcus lanatus*).

Simply stated, grasses have jointed stems (*culms*), which are usually solid at the joints (*nodes*) and round or compressed and usually hollow (solid in several groups) between the joints. The leaves are arranged in two vertical alternate ranks or rows, and are divided into a usually split tubular portion (the *sheath*) which surrounds the culm (exceptions to this are in *Melica*, *Glyceria*, and *Bromus*), a little hairy collar or membranous or firm projection (the *ligule*) at the inner junction of the sheath and blade, and the expanded or spreading flat or needle-like leafy part (the *blade*) with usually parallel nerves (when flattened).

The flowers of grasses have a specialized structure, and it is necessary to become acquainted with the elementary terminology used. A grass inflorescence or flower cluster is composed of units, known as *spikelets*, which are arranged in various ways (spikes, racemes, and panicles, and modifications of these). The stalk of each spikelet (if it has one) is the *pedicel*. The main axis of the inflorescence or the branches to which the spikelets are attached is the *rachis*.

An individual spikelet consists of 1 or 2 *florets* arranged on either side (if there are more than 1) of a central jointed axis (the *rachilla*). At the base of the spikelet are usually 2 empty bracts (*first glume* and *second glume*). Sometimes the first or second glumes are reduced or absent. Each floret has usually 2 other bracts: (1) an outer *lemma* and (2) an inner, often thinner, *palea* enclosed by the lemma. Sometimes the palea is minute or not present. Between the lemma and palea is the flower itself in which are usually three stamens (rarely 2 or 1), a 1-celled 1-ovuled ovary with 2 plume-like stigmas, and 2 (sometimes 3) tiny *lodicules*, which represent the modified sepals. The fruit is a one-seeded *caryopsis*, *achene*, or *utricle*.

Various modifications of the grass flower have produced the great diversity to be found within the family. Sometimes the basal end of the lemma is hardened as a *callus*, which may or may not be furnished with hairs. Sometimes a slender hair- or bristle-like appendage (awn) is attached to the glumes or lemmas. Sometimes, some of the spikelets are fertile and others are sterile or consist only of a pedicel.

The following key to the genera attempts to utilize and correlate vegetative, floral, and field characters in the identification of the grasses.

- a. Plants woody or with the culms (stems) perennial, the stems not dying back to the ground but starting from an already live stem above the ground; upper leaf-blades crowded, their sheaths overlapping and bearing bristles at the top 1. ARUNDINARIA
- a. Plants herbaceous or with the culms (stems) annual and dying back to the ground at the end of the season, with a new crop of stems arising from the ground each year either from the old root cluster or newly germinated plants b
- b. Spikelets enclosed in ball-shaped, spiny, barbed burs 72. CENCHRUS
- b. Spikelets not enclosed in spiny burs c
- c. Many soft or silky hairs conspicuous throughout the inflorescence (flowering portion), producing a feather-duster or plume-like effect (hairs may be present on various parts of the spikelets without producing the effect as here described, so look into the contrasting category of this same letter c) d
- d. Over-all color effect produced by whole inflorescence yellow-brown, due to brownish spikelets and fawn-colored hairs; ligule a prominent stiff, erect, cartilaginous stub 3-8 mm. long present at base of leaf-blade 78. SORGHASTRUM

- d. Over-all color effect produced by whole inflorescence either white, silvery, gray, straw-color, pinkish, or silvery and purplish, but not yellow-brown; ligule not a stiff erect cartilaginous stub 3-8 mm. long, but either consisting of a band or fringe of hairs, a short membranous collar or projection at most 2 mm. long e
- e. Leaf-blades 3-7 mm. wide; culms (stems) 0.3-1.5 meters tall; culms mostly 0.2-0.6 cm. in diameter f
- f. The conspicuous hairs of the flowering portion are chiefly on the rachis and pedicels or below the glumes 76. ANDROPOGON
- f. The conspicuous hairs of the flowering portion are on the margin of the fertile lemma, not on the rachis or pedicels 55. CHLORIS
- e. Leaf-blades 10-70 mm. wide; culms (stems) mostly 2-4 meters tall, mostly 0.7-1.5 cm. in diameter g
- g. Basal leaves mostly absent, the conspicuous ones being the widely spreading, 2-ranked leaf-blades on the culms (stems); leaf-blades 1-7 cm. wide; no awns present on spikelets; spikelets each 3-7-flowered, at least 2 of the flowers functional in each spikelet h
- h. Conspicuous hairs present are produced from the lemmas; rachilla glabrous (without hairs); cultivated grass, rarely naturalized 13. ARUNDO
- h. Conspicuous hairs present are produced from the rachilla and overtop the lemmas; lemmas glabrous; native plants of wet ground 14. PHRAGMITES
- g. Basal leaves often numerous or forming dense bushy clumps, the leaf-blades on the culms not conspicuously 2-ranked or horizontally spreading; leaf-blades 0.8-2 cm. wide; lemmas with a short to long awn; spikelets each with only 1 functional flower i
- i. Basal leaves very numerous, forming dense bushy clumps or rosettes; inflorescence (flowering portion) fan-shaped, its main axis shorter than its branches; axis and branches of inflorescence mostly glabrous, the conspicuous hairs present arising as a ring surrounding the base of each spikelet 73. MISCANTHUS
- i. Basal leaves few, either not conspicuous nor forming dense bushy clumps; axis of inflorescence much longer than the branches; axis and branches of inflorescence densely silky-hairy and a ring of hairs also present around the base of each spikelet 74. ERIANTHUS
- c. Soft or silky hairs absent throughout the inflorescence, or, if present, not conspicuous nor producing a feather-duster or plume-like effect j
- j. Inflorescence consisting of 1 (or presenting the appearance of 1) dense or closely-flowered spike (shaped like a pencil, tail, broom, brush, finger, shaft, hook, curve, or match stick), the spikelets surrounding all sides of the main axis, or with only their sides or edges next to the main axis (rachis) of the inflorescence (inflorescence may be hidden or enclosed in an enlarged leaf sheath) k
- k. Spreading or erect silky hairs present on joints of rachis and various pedicels (stalks) of sterile florets l
- l. A conspicuous stiff, erect, cartilaginous stub 3-8 mm. long present at base of leaf-blade; spikelets yellow- or chestnut-brown 78. SORGHASTRUM
- l. Without the above combination of characters 76. ANDROPOGON
- k. Without the above combination of characters m
- m. Bristles or awns (stiff or delicate, short or long, extension or outgrowth, usually from midrib of lemma or glume) on some part of the spikelets or at the base of the spikelets (hairs attached to or covering parts of spikelets should not be judged as bristles or awns here) n
- n. Slender bristles on the outside and at the base of each spikelet, but no awns arise from the glumes, lemma, or palea of the spikelets 71. SETARIA
- n. Awn (either stiff and bristly, or delicate and hair-like) attached to some part of the spikelet, but no bristles are on the outside or at the base of a spikelet (do not confuse bristle-like glumes of some species of *Elymus*, *Sitanion*, *Hystrix*, or *Hordeum*) o
- o. Lemma ending in a 3-awned tip 47. ARISTIDA
- o. Lemma without an awn or with only 1 awn at most, or awn occurring on glumes or palea p
- p. Spikelets with only one functional floret (use presence and location of glumes to judge where one spikelet ends and another begins), which may either be perfect, pistillate (pistil only), or staminate (stamens only) q
- q. Long awns present on both glumes and lemmas r
- r. Leaf-sheaths without any auricles (portions projecting from the edge) at the summit 25. HORDEUM
- r. Leaf-sheaths with auricles at the summit s

- s. Awns of lemma 6–10 cm. long 25. HORDEUM VULGARE
s. Awns of lemma at most 2.5 cm. long 22. ELYMUS
q. Long awn, when present, only on glumes or lemma, not on both *t*
t. Awn 11–20 cm. long; spikelets, excluding awn, 2.8–4 cm. long 46. STIPA
t. Awn 0.05–2 cm. long; spikelets, excluding awn, 0.25–1 cm. long *u*
u. Awn 1.5–2 cm. long; inflorescence 20–40 cm. long; plant 1–2 meters tall 74. ERIANTHUS
u. Awn 0.1–1.5 cm. long; inflorescence 2–15 cm. long; plant 0.3–1.5 meters tall *v*
v. Awns on glumes, not on lemmas *w*
w. Awns inconspicuous, at most 1 mm. long, much shorter than remainder of spikelet
40. PHLEUM
w. Awns conspicuous, 2–4 mm. long, as long as or longer than remainder of spikelet
41. MUHLENBERGIA
v. Awns on lemmas, not on glumes *x*
x. Awn arising from the back, but not the tip of the lemma *y*
y. A cluster of conspicuous fine hairs surrounds the lemma; plants about 1 meter tall
35. CALAMAGROSTIS
y. No cluster of prominent hairs surrounds the lemma; plants 0.1–0.8 meter tall *z*
z. Inflorescence brownish-yellow; glumes separate, not joined at the base
58. ANTHOXANTHUM
z. Inflorescence pale green, whitish-green, or drab; glumes united at the base
39. ALOPECURUS
x. Awn arising from some part of the tip of the lemma *i*
i. Awn inconspicuous, at most 1 mm. long, shorter than the remainder of the spikelet
66. ERIOCHLOA
i. Awn conspicuous, 3–15 mm. long, as long as or 2–4 times as long as remainder of spikelet 41. MUHLENBERGIA
p. Spikelet consisting of 2 or more functional florets (use presence and location of glumes to judge where one spikelet ends and another begins) 2
2. Entire plant velvety to the touch; awn with a small hook at tip; inflorescence with a dull rose to pink color 33. HOLCUS
2. Entire plant not velvety to the touch; awn lacking a hook at tip; inflorescence of other colors 3
3. Midnerve of lemma projecting as a minute awn less than 1 mm. long; side nerves of lemma frequently projecting above top of lemma as minute points; palea hairy on ridges; lemma hairy on keel (narrow ridge on back) or on marginal nerves 16. TRIDENS
3. Without the above combination of characters 4
4. Some or all of the spikelets separated from the main axis of the inflorescence by pedicels (stalks) 5
5. Awn arising from the back of the lemma on at least one of the florets; spikelets 2-flowered
32. ARRHENATHERUM
5. Awn arising at the very tip of the lemma either between two teeth or lobes or simply as a simple projection from a toothless lemma; spikelets 3–many-flowered 6
6. Both glumes and lemmas with prominent long awns 25. HORDEUM JUBATUM
6. Only the lemmas with conspicuous awns 7
7. Glumes much longer than all the lemmas (excluding the awns), 8.5–13 mm. long; perennials with old leaves at base and with a fresh cluster of basal rosette leaves; ligule in the form of erect conspicuous hairs 34. DANTHONIA
7. Glumes shorter than the rest of the spikelet, 2–5 mm. long; annuals with delicate roots, with few leaves, the leaves not clustered at the base 3. FESTUCA
4. Spikelets all attached directly to the rachis (sessile) 8
8. Only 1 spikelet at each joint (node) of the rachis 9
9. Both glumes and lemmas with long conspicuous awns 22. ELYMUS
9. Only glumes or lemmas, but not both, with conspicuous long awns 10
10. Spikelets placed with their sides to the rachis; both glumes present on each spikelet 11
11. Spikelets cylindrical, fitting into the depressions or pockets of the rachis, appearing as part of the diameter of the rachis 20. AEGILOPS
11. Spikelets more or less flattened, but obviously distinct from and not appearing as part of the rachis 12
12. Awns conspicuous, 1.5–8 cm. long (sometimes shorter on lowest spikelet) 13

- 13. Glumes ovate, 3-nerved 19. TRITICUM
- 13. Glumes subulate (very narrow), 1-nerved 21. SECALE
- 12. Awns shorter or inconspicuous 18. AGROPYRON
- 10. Spikelets placed with their narrow edge to the rachis; except for the uppermost spikelet, only one glume present (the one away from the rachis) 26. LOLIUM
- 8. A group of 2 or 3 spikelets at each joint (node) of the rachis 14
- 14. Spikelets in 3's at each joint, 1-flowered 25. HORDEUM
- 14. Spikelets in 2's at each joint, 2-6-flowered 15
- 15. Glumes 6-8 cm. long; main axis (rachis) of inflorescence breaking up into segments upon reaching maturity; rare introduced plant 23. SITANION
- 15. Glumes 1-4 cm. long; main axis of inflorescence persistent at maturity, not breaking up into segments; common native plants 16
- 16. Spikelets outwardly spreading, or spreading at right angles from the rachis at maturity; glumes not present or reduced to little bristles 24. HYSTRIX
- 16. Spikelets ascending, erect, or upwardly pointing at maturity with reference to the axis of the inflorescence (spikes which are nodding or curving should be considered accordingly); glumes usually conspicuous or evident 22. ELYMUS
- m. No bristles or awns present in the inflorescence (hairs attached to or covering parts of the spikelets may be looked for here, and should not be judged as bristles or awns) 17
- 17. Spikelets appearing as if part of the diameter of the main axis (rachis) of the inflorescence, fitting into the depressions or sunken portions of the rachis; outermost part of spikelet (1st glume) with little pits 79. MANISURIS
- 17. Spikelets not as above, but distinct and separate from the rachis, and not appearing to be part of it 18
- 18. Sexes of spikelets in separate inflorescences, the staminate (male) at the summit of the plant, the pistillate (female) lower down in the axils of the leaves 81. ZEA
- 18. Both stamens and pistils in the same florets 19
- 19. Lemmas with a 3-lobed (cross-like) tip 25. HORDEUM
- 19. Lemmas without a 3-lobed (cross-like) tip 20
- 20. Spikelets placed with their narrow edge to the rachis; except in the uppermost spikelet, only the glume away from the rachis present (one glume present) 26. LOLIUM
- 20. Spikelets placed with their sides to the rachis or encircling all sides of the rachis; both glumes present 21
- 21. Each spikelet consisting of 2 or more functional florets 22
- 22. Individual spikelets 2-5 mm. long, usually 2- or 3-flowered 23
- 23. Main axis of inflorescence densely short-hairy; spikelets mostly 4-5 mm. long; glumes and lemmas acutely pointed and narrowed at tip 27. KOELERIA
- 23. Main axis of inflorescence glabrous or slightly scabrous; spikelets mostly 2-3.5 (rarely 4) mm. long; at least the glumes rounded or blunt at tip 28. SPHENOPHOLIS
- 22. Individual spikelets 7-22 mm. long, 2-5-flowered 24
- 24. Spikelets on very short or else noticeable pedicels (stalks); spikelets 5-12 mm. long 16. TRIDENS
- 24. Spikelets without stalks (sessile), arising directly from each joint of the rachis; spikelets 10-22 mm. long 25
- 25. Two or 3 spikelets at each joint (node) of the rachis 22. ELYMUS
- 25. Only 1 spikelet at each joint (node) of the rachis 26
- 26. Plants producing long creeping rhizomes 18. AGROPYRON
- 26. Plants not producing creeping rhizomes 27
- 27. Glumes lanceolate, acute; lemma with an acute or narrowly tapering tip and obscurely ridged at the middle; leaves 2-10 mm. wide; plants perennial 18. AGROPYRON
- 27. Glumes ovate, blunt, strongly keeled toward one side; lemma rounded or blunt at tip, keeled; leaves 10-20 mm. wide; annuals 19. TRITICUM
- 21. Each spikelet consisting of only one functional floret, which may be perfect, pistillate (pistil only), or staminate (stamens only) 28
- 28. Glumes longer than the lemma and palea; ligule large or noticeable as a membranous prolonged part 59. PHALARIS

28. Glumes shorter than or at most equaling the length of the lemma and palea; ligule a zone of hairs or a collar 0.5 mm. high or none at all. 29
29. Lemma faintly 3-5-nerved; inflorescence not projecting from an inflated sheath 41. MUHLENBERGIA
29. Lemma 1-nerved; inflorescence partly or wholly enclosed in, or protruding from, an inflated sheath 30
30. Ligule a zone of hairs; leaves mostly 4-10 cm. long, at most 25 times longer than broad; spike densely flowered, 6-10 mm. thick; rarely found 43. HELEOCHLOA
30. Ligule minute or none; leaves usually 10-100 cm. long, averaging 40-100 times longer than broad, or, if less than 10 cm. long, then the inflorescences are 2-5 mm. thick, or loosely-flowered, or elongated; common. 42. SPOROBOLUS
- j. Inflorescence not appearing as 1 dense or closely-flowered spike, but as other types of arrangements which have 1 or usually 2 or more or many separate units or branches, these separate units or branches branched or unbranched and usually several to many times longer than broad 31
31. Inflorescence shaped like a V, pitchfork, rays of an umbrella, spokes of a wheel, fingers on a hand, toes of a bird, or all the separate units hanging at an angle like a flag, or comb-like, feather-like, stepladder-like, or flattened tree-like, all units or *all* lateral units of the inflorescence *unbranched*, and usually several to many times longer than broad, sometimes short, the spikelets usually 1-flowered (sometimes many-flowered), and usually along one side of the axis (rachis) 32
32. Inflorescence shaped like a V, pitchfork, rays of an umbrella, spokes of a wheel, fingers of a hand, or toes of a bird, these units closely crowded at the top of the stem 33
33. Leaf-blades ovate to ovate-lanceolate, with curved sides, 3-4 times longer than broad 75. ARTHRAXON
33. Leaf-blades linear with more or less parallel sides, many times longer than broad 34
34. Plants 1-3 meters tall, averaging close to the height of a man 35
35. Leaf-blades 1-3.5 cm. wide; inflorescence at the top of the culm (stem), consisting of 2-4 spikes which are pistillate (female) in the lower portion; no awns present on any part of the spikelets. 80. TRIPSACUM
35. Leaf-blades 0.5-1 cm. wide; inflorescence at the top of the culm (stem), consisting of 2-6 or more densely-flowered racemes with no separate pistillate (female) portion; awns present on some (fertile lemma) of the florets. 76. ANDROPOGON GERARDI
34. Low plants averaging only 0.05-0.4 meters tall, averaging about knee-high or less on a person 5'9" tall 36
36. Sexes of spikelets separated, either the staminate (male) and the pistillate (female) on separate plants or in different inflorescences of the same plant 37
37. Spikelets many-flowered, either all staminate (male) or all pistillate (female) on separate plants 7. ERAGROSTIS REPTANS (pistillate plant)
37. Staminate and pistillate inflorescences separated on the same plant, the staminate at the top, the pistillate lower down in the axils of the leaves; spikelets 1-2-flowered 81. ZEA
36. Sexes of spikelets not separated, spikelets perfect, with the staminate (male) and pistillate (female) parts together in the same floret 38
38. Awns present on some part of the spikelet 55. CHLORIS
38. No awns on any part of the spikelet 39
39. Spikes rather thick, 5-7 mm. wide; ligule an irregularly cut collar with some long hairs at the sides 49. ELEUSINE
39. Spikes slender, 0.5-2 mm. wide; ligule a band of white hairs or short membranous collar 40
40. All the rays (spikes) horizontally spreading or nearly so; ligule a conspicuous band of white hairs; plants forming creeping dense mats from hard scaly rhizomes or long stolons, the leaves 2-4 mm. wide 50. CYNODON
40. Most of the rays (spikes) ascending to erect, not horizontally spreading; ligule a membranous projecting collar; plants either tufted and not creeping or rooting at the lower nodes (joints) and forming loose colonies, those from the rooting type with leaves 3-10 mm. wide 64. DIGITARIA

32. The separate rays or branches of the inflorescence separated in such a manner as to appear pinnately branched often on two sides of a main axis, or only on one side, resembling the arrangements of a flattened feather, of a flattened tree with main branches, of a comb, of a stepladder, or of a hanging flag 41
41. Spikes (not spikelets) all nodding, numerous, usually only on 1 side or on 2 sides of the main rachis of the inflorescence, 1-2 cm. long 56. *BOUTELOUA CURTIPENDULA*
41. Spikes either erect, ascending, widely spreading, or the lower ones drooping, from 1, 2, or more sides of the main axis of the inflorescence 42
42. At least the *lowest* spikes or branches widely or horizontally spreading or drooping 43
43. Rachis of the lateral (side) racemes or spikes leaf-like, wider than and with their margins arching over the spikelets; plants growing in the water or nearly aquatic. 68. *PASPALUM*
43. Rachis not leaf-like, not as wide as the rows of spikelets; plants of dry or wet soils, sometimes in the water 44
44. Some of the hairs of the spikelets with swollen or blister-like bases; ligule absent; sheaths compressed; plants often of wet soils or even growing in the water. 70. *ECHINOCHLOA*
44. Without the above combination of characters 45
45. Plants 1-5 meters tall (or smaller in young, poor, or undernourished specimens); culms (stems) 0.5 cm. or more (usually 1.5-10 cm.) in diameter; leaf-blades 3-8 cm. wide 81. *ZEA*
45. Plants 0.15-0.6 meters tall; culms (stems) 1-3 mm. in diameter; leaf-blades 1-12 mm. wide 46
46. Spikes 1-3, about 4.5-6 mm. wide (excluding the awn), 2-4 cm. long, rather thick and densely flowered 56. *BOUTELOUA*
46. Spikes more numerous, 0.5-2 mm. wide (excluding the awns), usually 5-15 cm. long, slender and loosely flowered 47
47. Awns absent on all part of the inflorescence 48
48. Spikelets 2-4-flowered 48. *LEPTOCHLOA*
48. Spikelets 1-flowered 49
49. Spikelets glabrous 51. *SCHEDONNARDUS*
49. Spikelets with short bristle-like hairs 61. *LEERSIA*
47. Awns present on some part of the inflorescence 50
50. Plants of dry, rocky, or acid soils; inflorescence about as broad as long, dome-shaped; leaf-blades of the main stem rather stiff, mostly horizontally spreading, 4-10 cm. long, chiefly 4-6 times longer than broad; spikelets 6 mm. long; awn 4.5-9 mm. long 54. *GYMNOPOGON*
50. Plants of wet or alluvial soils; inflorescence mostly longer than broad; leaf-blades of main stem strongly ascending, chiefly 7-40 cm. long (except shorter in depauperate individuals), mostly 12-30 times longer than broad; spikelets up to 2.5 mm. long; awn 1 mm. or less long 48. *LEPTOCHLOA*
42. All the spikes erect or ascending, or, if spreading, not horizontally so 51
51. Rachis (axis) of the lateral (side) racemes or spikes leaf-like, wider than and with their margins arching over the spikelets; plants growing in the water or nearly aquatic 68. *PASPALUM*
51. Rachis (axis) not leaf-like, not as wide as the rows of spikelets; plants of dry or wet soils 52
52. Spreading or erect silky hairs present on joints of rachis or on various sterile pedicels (stalks) 76. *ANDROPOGON*
52. Not as above 53
53. Some of the hairs of the spikelets with swollen or blister-like bases; sheaths compressed; ligule absent; plants often of wet soils, or even growing in the water. 70. *ECHINOCHLOA*
53. Without the above combination of characters 54
54. Awns absent on all parts of the spikelets (spikelets with minute awns only 0.5-1 mm. long should be looked for in the opposite section of this number 54). (Awns may be present only on uppermost glumes of staminate florets in no. 66, which should be looked for in opposite section of this number 54) 55

55. Spikelets 5-many-flowered 56
56. Leaf-blades and culms (stems) pubescent; culms spreading; leaf-blades not stiff; spikelets 1-4 mm. wide 7. ERAGROSTIS REPTANS
56. Leaf-blades and culms (stems) glabrous; culms upright or nearly so; leaves stiff; spikelets 4-5.5 mm. wide 10. DISTICHLIS
55. Spikelets 1-flowered 57
57. Some part of the spikelet either with cross-wrinkles or with veins running cross-wise or at various angles 58
58. Ligule conspicuous, prolonged, membranous, 4 mm. long; both glumes cross-wrinkled, both folded; spikes numerous, overlapping, erect or strongly ascending, 1-2 cm. long 52. BECKMANNIA
58. Ligule a band of hairs 0.5-0.6 mm. high; the outside lowest glume not cross-veined; the inner glume and sterile lemma with few weak cross-veins; glumes not folded; inflorescences 2-6, ascending or spreading, not overlapping, 3-8 cm. long 67. BRACHIARIA PLATYPHYLLA
57. No cross wrinkles or cross veins or angled veins on the spikelet 59
59. Spikelets projecting conspicuously from the rachis at different angles; spikelets on short pedicels (stalks) and set at an angle to them, pointing in different directions away from the rachis, not parallel to the rachis, nor appearing flattened, nor crowded against one another 69. PANICUM
59. Spikelets conforming to the length of the rachis, not conspicuously standing out from the rachis; spikelets either appearing flattened against or parallel to or along the rachis, or crowded so that they lie upon or overlap each other 60
60. First glume present and rounded, truncate, or obtuse; spikelets glabrous 69. PANICUM
60. Without the above combination of characters 61
61. Spikes usually 10-50, elongated and slender, 0.5-2 mm. wide, at first ascending, at maturity widely spreading; spikelets well separated from one another 62
62. Plants of dry soils; leaf-blades 1-2 mm. wide; spikelets 4 mm. long, glabrous; spikes mostly alternate, distant and well separated from each other by gaps of as much as 8 cm. 51. SCHEDONARDUS
62. Plants of wet or alluvial soils; leaf-blades mostly 5-10 mm. wide; spikelets 1-2 mm. long, the lemmas hairy; spikes alternate or opposite, most of them spaced rather closely together with a gap often of only 0.5-2 cm. separating them 48. LEPTOCHLOA
61. Spikes or racemes usually 1-10, rather thick, 1.5-5 mm. wide, ascending to somewhat erect; spikelets closely crowded or overlapping 63
63. Spikes less than 1 cm. long, 1.5 mm. or less wide 67. BRACHIARIA ERUCAEFORMIS
63. Spikes or racemes 1-15 cm. long, 1.5-7 mm. wide 64
64. Spikelets rounded or blunt at tip 68. PASPALUM
64. Spikelets acutely or narrowly pointed at tip 65
65. Racemes usually not over five times longer than broad, mainly 1-2 cm. long; ligule absent; leaf-sheaths compressed 70. ECHINOCHLOA
65. Racemes 10-20 or more times longer than broad, 8-12 cm. long; ligule a membranous whitish projection; leaf-sheaths not compressed 68. PASPALUM
54. Awns present on some part of the spikelets or rachis (in no. 66 awns may be present only on glumes of uppermost staminate florets) 66
66. Spikelets 4-10-flowered 67
67. Lemmas with two minute teeth at tip, 1-3-nerved 8. DIPLACHNE
67. Lemmas with a simple tapering tip, faintly 5-nerved 3. FESTUCA
66. Spikelets 1-flowered 68
68. Leaf-blades 1-3 mm. wide; comb-like spikes 1-3 69
69. Plants sending out horizontal branches (stolons) which develop new stems and leaves at the nodes (joints); spikes 0.5-1.5 cm. long 57. BUCHLOE (staminate plant)
69. Plants in single clumps lacking horizontal runners; spikes 2-4 cm. long 56. BOUTELOUA
68. Leaf-blades mainly 4-15 (rarely 3) mm. wide; spikes 5 to many 70
70. Leaf-blades ovate to ovate-lanceolate with curved sides, 3-4 times longer than broad 75. ARTHRAXON
70. Leaf-blades linear to lanceolate, with parallel sides, 4-50 times or more longer than broad 71

71. Spikes 3-10 mm. wide, the spikelets congested, placed next to one another or conspicuously close and overlapping 72
72. Plants with stout scaly rhizomes forming colonies; leaf-blades with sharp edges cutting the flesh, their surfaces rough; spikes conspicuously erect to ascending; spikelets conspicuously 1-sided, all slanting and crowded in the same direction parallel to one another. 53. SPARTINA
72. Without the above combination of characters 73
73. Some part of the spikelet prominently nerved; some of the hairs on the spikelet often with a blister-like or swollen base (papillose-hispid) or rather stiff 70. ECHINOCHLOA
73. No part of the spikelet nerved; all the hairs on the spikelets fine and soft 66. ERIOCHLOA
71. Spikes 0.5-2 mm. wide (not including the awns); spikelets loose on the rachis, not conspicuously close and overlapping 74
74. Plants of dry, rocky, or acid soils; inflorescence about as broad as long, dome-shaped; leaf-blades of the main stem rather stiff, mostly horizontally spreading, 4-10 cm. long, chiefly 4-6 times longer than broad; spikelets 6 mm. long; awn 4.5-9 mm. long. 54. GYMNOPOGON
74. Plants of wet or alluvial soils; inflorescence mostly longer than broad; leaf-blades of main stem strongly ascending, chiefly 7-40 cm. long (except shorter in depauperate individuals), mostly 12-30 times longer than broad; spikelets up to 2.5 mm. long; awn 1 mm. or less long. 48. LEPTOCHLOA
31. Inflorescence of many other types, as stated in the contrasting sections of number 81 (pages 75 and 77), but not as defined in the other (alternative) section of this number 31 75
75. Spikelets either pistillate (female) or staminate (male), the two sexes not in the same floret (use fresh flowering-plants and do not confuse too mature or fruiting plants which have lost their stamens with one-sexed spikelets) 76
76. Pistillate (female) and staminate (male) flowers on *different* plants; plants low, 3-40 cm. tall, with creeping rhizomes or stoloniferous branches (sending out horizontal runners which root at the joints) 77
77. Inflorescence nearly hidden by and scarcely protruding from the broad bases of the upper leaves; inflorescence of 3-5 spikelets; spikelets bunched together into a dense short head about 8 mm. long; some parts of the spikelets narrowed above into a 3-lobed summit 57. BUCHLOE (pistillate plant)
77. Inflorescence standing out and well separated from the leaves; inflorescence of separate and several or many spikelets; all parts of the spikelet with a simple unlobed summit 78
78. Leaf-blades and culms (stems) pubescent; culms spreading; leaf-blades not stiff; spikelets 1-4 mm. wide 7. ERAGROSTIS
78. Leaf-blades and culms (stems) glabrous; culms upright or nearly so; leaf-blades stiff; spikelets 4-5.5 mm. wide 10. DISTICHLIS
76. Pistillate (female) and staminate (male) flowers at different locations on the same plant; plants 1-3 meters tall (or lower in poor, undernourished, or young specimens) 79
79. Common cultivated plant, sometimes growing along roadsides, woodland areas, or vacant ground; staminate (male) and pistillate (female) spikelets in separate inflorescences, the staminate at the summit of the plant, the pistillate lower down in the axils of the leaves 81. ZEA
79. Native plants growing in the water of swamps or ponds; staminate and pistillate spikelets at different locations on the same inflorescence 80
80. Pistillate (female) spikelets only on the uppermost upright branches of the inflorescence, the staminate (male) on the lower spreading branches; leaf-blades soft, not with sharp edges; scattered in various parts of Missouri 62. ZIZANIA
80. Pistillate (female) spikelets on the same branch as the staminate (male); leaf-blades with sharp edges cutting the flesh easily; swamps and sink-hole ponds of southeastern Missouri only 63. ZIZANIOPSIS
75. Spikelets perfect, usually both pistillate (female) and staminate (male) in the same floret (occasionally sterile or imperfect florets present) 81
81. Inflorescence of a narrow elongated type, the side branches remaining close to the main axis of the inflorescence 82
82. Spreading or erect brown, gray, or white hairs on joints of rachis and various sterile pedicels (stalks) or around base of each floret 83
83. A conspicuous stiff, erect, cartilaginous stub (stipule) 3-8 mm. long present at base of leaf-blade; spikelets yellow or chestnut-brown 78. SORGHASTRUM
83. Without the above combination of characters 76. ANDROPOGON

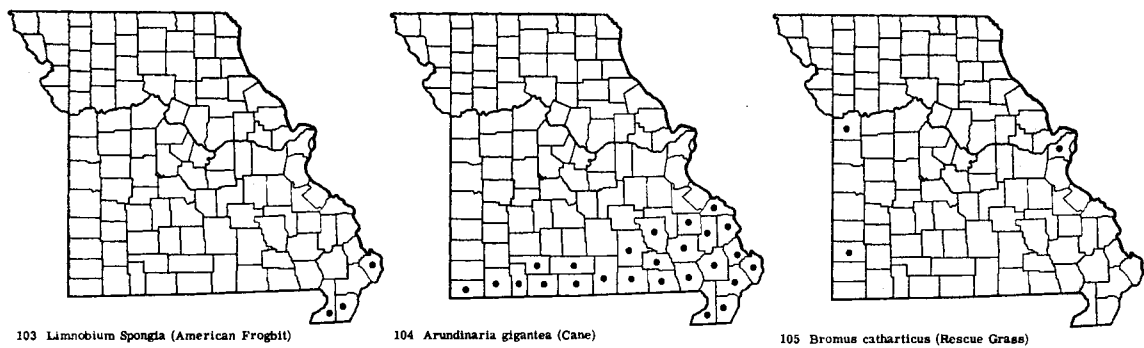

82. Not as above 84
84. Entire plant velvety to the touch; awn with a small hook at tip; inflorescence with dull rose or pink color 33. *HOLCUS*
84. Not as above 85
85. Three bristle-like awns (2 of them sometimes mere stubs or short projections) at the summit of lemma 47. *ARISTIDA*
85. Awn, if present, only 1 at summit of lemma or glumes 86
86. Awn 11-20 cm. long; spikelet, excluding awn, 2.8-4 cm. long 46. *STIPA*
86. Awn, if present, at most 4 cm. long 87
87. Prominent or minute awns (bristle- or hair-like extensions of nerves of lemmas or glumes) present on some part of the spikelets (hairs attached to or covering parts of the spikelets should not be judged as awns) 88
88. Each spikelet consisting of only 1 functional floret, which may be perfect, pistillate (pistil only) or staminate (stamens only) 89
89. Awns conspicuous, projecting noticeably beyond the length of spikelet, 3-25 mm. long 90
90. Spikelet, excluding the awn, 2-4.5 mm. long; spikelets relatively numerous 41. *MUHLENBERGIA*
90. Spikelet, excluding the awn, 6-11 mm. long; spikelets relatively few 91
91. Awns bent or twisted at base; sterile stalked spikelets present 77. *SORGHUM*
91. Awns straight, not bent or twisted at base; all spikelets fertile 92
92. Spikelets (excluding awn) 10-14 mm. long, about 1.5-1.7 mm. wide, 7-9 times longer than broad, narrowly linear-lanceolate and not noticeably wider at the middle; leaves mostly spreading, mostly 6-11 times longer than broad 44. *BRACHYELYTRUM*
92. Spikelets (excluding awn) 7-9 mm. long, 2-2.5 mm. wide, 2½-3 times longer than broad, elliptic, noticeably wider at the middle; leaves erect to ascending, mostly 15-25 times longer than broad 45. *ORYZOPSIS*
89. Awns inconspicuous, 0.5-2 mm. long 93
93. Soft hairs arise from the base of the lemma and surround the lemma 35. *CALAMAGROSTIS*
93. Not as above 38. *CINNA*
88. Each spikelet consisting of 2 to several florets 94
94. Some or all of the spikelets separated from the main rachis by their own pedicels (stalks) 95
95. Leaves dark green, shining, 10-18 mm. wide; plants spreading from a hard scaly rhizome (underground stem) 9. *DIARRHENA*
95. Not as above 96
96. Awn arising from the back of the lemma on at least one of the florets; spikelets 2-flowered 32. *ARRHENATHERUM*
96. Awn arising at the very tip of the lemma, either between 2 teeth or simply as a prolongation or projection from a toothless lemma; spikelets 3-many-flowered 97
97. Spikelets conspicuously crowded or overlapping, and in groups of dense 1-sided cluster 12. *DACTYLIS*
97. Spikelets not as above 98
98. Ligule in the form of erect conspicuous hairs; glumes much longer than all the lemmas (excluding the awns), 8.5-13 mm. long 34. *DANTHONIA*
98. Ligule a white or brown membranous projection; glumes shorter than the rest of the spikelet, 2-5 mm. long 3. *FESTUCA*
94. Spikelets all attached directly to the main rachis (sessile) 99
99. Spikelets conspicuously crowded or overlapping, and in groups of dense, 1-sided clusters 12. *DACTYLIS*
99. Spikelets not as above 100
100. Spikelets placed with their narrow edge to the rachis; except for the uppermost spikelet, only the glume away from the rachis present (1 glume present) 26. *LOLIUM*

100. Spikelets placed with their sides to the main rachis or spreading away from the rachis; both glumes present	101
101. Spikelets outwardly spreading or spreading at right angles to the rachis at maturity; spikelets 2-3 at each joint (node) of the rachis.	24. HYSTRIX
101. Spikelets erect, ascending, or pressed against the rachis (axis); spikelets 1 at each joint (node) of the rachis	18. AGROPYRON
87. No awns on any part of spikelet (lemma taper into a short stout point [cusp] in <i>Diarrhena</i> which is keyed out here and in previous part of number 87)	102
102. Each spikelet consisting of only 1 functional floret, which may be perfect, pistillate (pistil only) or staminate (stamens only)	103
103. Glumes and lemmas rounded or obtuse at summit.	69. PANICUM
103. Glumes and/or lemmas distinctly short- or long-pointed	104
104. Glumes longer than the rest of the spikelet (fertile and sterile lemma and palea); ligule conspicuous, 9-10 mm. long	59. PHALARIS ARUNDINACEA
104. Glumes shorter than to equaling the lemma and palea; ligule minute or at most 2 mm. long	41. MUHLENBERGIA
102. Each spikelet consisting of 2 to several florets.	105
105. Spikelets 2-3-flowered, 2.5-4.2 mm. long	28. SPHENOPHOLIS
105. Spikelets 3-many-flowered, 7-22 mm. long	106
106. Some or all of the spikelets separated from the main rachis by their own pedicels (stalks)	107
107. Spikelets conspicuously crowded or overlapping, and in groups of dense 1-sided clusters	12. DACTYLIS
107. Spikelets not as above.	108
108. Spikelets some shade of lavender-rose; plants of sunny limestone glades and bluffs; ligule consisting of short hairs; hairs present on nerves at base of lemma	16. TRIDENS
108. Spikelets gray-green or straw-colored; plants of water, swampy ground, or woodland; ligule a short cartilaginous collar or a thin whitish membrane; lemma glabrous	109
109. Leaves dark green, shining; plants of woodland; lemmas rigid, firm, sharply pointed	9. DIARRHENA
109. Leaves gray- or blue-green, dull; plants of water, ponds, or swamps; lemmas soft, thin, rounded or blunt at tip	5. GLYCERIA
106. Spikelets all attached directly to the main rachis (sessile)	110
110. Plants growing in water of ponds, or in swampy ground; lemmas blunt or rounded at tip; glumes and lemmas thin or membranous	5. GLYCERIA
110. Plants growing in other situations, usually in drier ground; lemmas usually acute or pointed at tip; glumes and lemmas mostly firm.	111
111. Spikelets placed with their narrow edge to the rachis; except for the uppermost spikelet, only the glume away from the rachis present (1 glume present)	26. LOLIUM
111. Spikelets placed with sides to the rachis; both glumes present. 18. AGROPYRON	
81. Inflorescence with some or all of the side branches outwardly spreading, the lower branches often longer and more spreading, the inflorescence as a whole with the shape either of a narrow to broad triangle, pyramid, spire, or Christmas tree, or as broad or broader than long (some variations of the alternative section of this number 81 are placed here, and variations normally placed at this point in the key should be looked for in the other section of this same number)	112
112. Entire plant velvety to the touch; awn with a small hook at tip; inflorescence with a dull rose or pink color	33. HOLCUS
112. Without the above combination of characters.	113
113. Each spikelet consisting of only one functional floret, which may be perfect, pistillate (pistil only), or staminate (stamens only)	114
114. Spreading or ascending silky hairs present on joints of rachis or various sterile pedicels (stalks); or if not giving that appearance, then sterile pedicels present	115
115. One, two, or more unbranched units of an inflorescence protruding from the sides or in the axils of a leafy stem	76. ANDROPOGON
115. Complete inflorescence at the tip of the stem, obviously branched into many sections	116

116. Ligule or auricle stiff, cartilaginous, 3-8 mm. long; lower main nodes (joints) or axils of inflorescence without hairs; spikelets yellow- or chestnut-brown; some pedicels (stalks) occur without a spikelet at the tip; native grass of prairies, glades, prairie strips along railroads, and open woods. 78. *SORGHASTRUM*
116. Ligule hairy or membranous, 1-3 mm. long; lower main nodes (joints) or axils of inflorescence hairy; spikelets often tinged with rose, or purplish; pedicellate (stalked) spikelet a staminate (male) spikelet at tip of pedicel; introduced forage grass found in fields, bottomland, along roadsides, and waste ground 77. *SORGHUM*
114. No spreading or ascending silky hairs present on joints of rachis nor sterile pedicels present, but a tuft of spreading hairs may arise from the base of a floret 117
117. Three bristle-like awns (2 of them sometimes mere stubs or short projections) at summit of lemma 47. *ARISTIDA*
117. Awn, if present, only 1 on the lemma or glume 118
118. Awns on some part of the spikelet (hairs attached to or covering parts of the spikelet should not be judged here as awns) 119
119. Spikelet 3-4 mm. wide; prominent depressions and vertical keels (ridges) on the spikelet (on lemma) with dotted roughened surface between the ridges; plant found as an escape from cultivation 60. *ORYZA*
119. Spikelet 0.5-2.5 mm. wide; no prominent keels or depressions or dotted roughened surface on spikelet; native plant 120
120. Spikelet prominently nerved; hairs on spikelet with usually some blister-like or enlarged bases (pustulose); ligule not present 70. *ECHINOCHLOA*
120. Without the above combination 121
121. Spikelets 7-9 mm. long, relatively few and scattered in the inflorescence 45. *ORYZOPSIS*
121. Spikelets 2-6 mm. long, relatively many 122
122. Spikelets quite compressed or flattened on the sides; ligule 3-5 mm. long; stamen 1 38. *CINNA*
122. Spikelets turgid, filled out more or less equally from all sides, not noticeably flattened; ligule 0.5-3 mm. long 123
123. Awn, if present, at the tip of the lemma; glumes mostly unequal, both glumes shorter than the lemma or usually one of them shorter than the lemma 41. *MUHLENBERGIA*
123. Awn arising from some point on the back of the lemma (dorsally); lemma loosely embracing the grain; glumes mostly equal, either equaling the lemma or the first glume longer than the lemma 124
124. Hairs at base of lemma present or absent, but, if present, either few, short and inconspicuous, or attaining to $1/3-1/2$ length of spikelet, but not subtended by a tuft of hairs from a hard projection (callus) at base of lemma; 2nd glume 1-nerved; spikelets about 2 mm. long; annuals, 2-7 dm. tall, with delicate roots 37. *AGROSTIS*
124. A conspicuous tuft of spreading hairs surrounds $1/2$ to nearly length of lemma and arises from a hard projection (callus) at its base; 2nd glume 3-nerved; spikelets 2.2-5.5 mm. long; perennial plants, 5-15 dm. tall, with strong roots 35. *CALAMAGROSTIS*
118. No awn present on any part of spikelet (hairs attached to or covering parts of the spikelet should not be judged as awns) 125
125. Spikelets conspicuously flattened on the sides (laterally); main part of spikelet (lemma) with prominent keels (sharp ridges) on the sides or margins, or the keels on the margins with short bristle-like hairs 126
126. Surface of spikelet between the keels with dotted roughened surface; spikelets 7-10 mm. long, rather thick; plant found as an escape from cultivation 60. *ORYZA*
126. Surface of spikelet between the keels not dotted roughened; keels on the margins of spikelets with conspicuous short bristle-like hairs; spikelets 3-5 mm. long, thin, and flattened; native plants growing in or near the water or in wet woodland 61. *LEERSIA*

125. Spikelets turgid, filled out more or less equally from all sides, not noticeably flattened . . . 127
127. Spikelets not all perfect (both stamens and pistil in a perfect floret), each group of spikelets in 2's or 3's with 1 of them sessile (without stalks) and perfect, the other or other spikelets staminate (male) or sterile and on pedicels (stalks) with a short feathery beard . . . 77. *SORGHUM*
127. Spikelets all perfect (with stamens and pistil in the same floret), either all on short or long pedicels (stalks), but not as described above . . . 128
128. A hard projection (callus) present at base of lemma with a conspicuous beard of hairs surrounding the lower half of the lemma; ligule a fringe of bristles . 36. *CALAMOVILFA*
128. Without the above combination of characters . . . 129
129. Outermost parts of floret (2 unequal glumes, a sterile lemma resembling a 3rd glume, and a palea) thinner and of a different texture from the thicker, more cartilaginous or leathery inner fertile lemma and palea (do not consider for this section the lemma which closely envelops the grain in *Muhlenbergia*) . . . 130
130. Ligule a collar-like projection, not hairy; the whole inflorescence with a rosy-purplish color; conspicuous lines or streaks of short silky hairs flattened along the nerves and white margins of the second glume and sterile lemma; pedicels (stalks) of spikelets 3-angled at the summit . 65. *LEPTOLOMA*
130. Ligule a dense band of hairs or a collar fringed with hairs; the whole inflorescence usually shades of green or brownish-yellow (purplish or reddish in a few species, such as *P. capillare*, *P. virgatum*, and others); no conspicuous lines or streaks of short silky hairs on the florets; pedicels (stalks) of spikelets terete (circular when cut crosswise) . . . 69. *PANICUM*
129. Outermost parts of floret (glumes) about as thin as inner parts (lemma and palea) . . . 131
131. Ligule a close fringe or band of bristles; lemma 1-nerved . 42. *SPOROBOLUS*
131. Ligule a thin membranous collar; lemma 3-5-nerved . . . 132
132. Lemma usually with hairs at base (no hairs in *M. glabriflora* and *M. asperifolia*); lemma tightly embracing the grain; glumes mostly unequal, both glumes shorter than the lemma or usually one of them shorter than the lemma . . . 41. *MUHLENBERGIA*
132. Lemma usually without hairs at its base; lemma loosely embracing the grain; glumes mostly equal, either equaling the lemma or the first glume longer than the lemma . . . 37. *AGROSTIS*
113. Each spikelet consisting of 2 or more functional florets . . . 133
133. An awn present on some part of the spikelet (hairs attached to or covering parts of the spikelet should not be judged here as awns) . . . 134
134. Nodes (joints) of culms (stems) conspicuously bearded with spreading white hairs; leaf-sheaths inflated; upper keeled margin of palea densely bearded; the 3 nerves of lemma strongly hairy . . . 17. *TRIPLASIS*
134. Without such a combination of characters . . . 135
135. Spikelets tiny, at most 2.2 mm. long (excluding the awn), and solitary at the tips of long spreading pedicels (stalks) . . . 30. *AIRA*
135. Spikelets much longer, 5-100 mm. long . . . 136
136. Ligule in the form of erect, stiff, noticeable hairs; glumes longer than the lemmas; spikelets 2-13 . . . 34. *DANTHONIA*
136. Ligule not of stiff hairs, either a shallow band or rounded or triangular membranous projection or with an irregularly cut tip with or without a few short hairs; glumes either shorter than the spikelets or the lower fertile lemma, or only 2-3-flowered; spikelets more numerous . . . 137
137. Spikelets conspicuously crowded or overlapping, and in groups of dense 1-sided clusters, nearly sessile (stalkless); individual spikelets only slightly longer than broad or clusters of spikelets not much longer, if at all longer than broad . . . 12. *DACTYLIS*
137. Without the above combination, the spikelets obviously scattered on the branches, or, if slightly clustered, on usually noticeable pedicels (stalks); spikelets either much longer than broad, or inflorescence as a whole longer than broad . . . 138

138. Glumes 20 mm. or more long 31. AVENA
138. Glumes 0.5-15 mm. long 139
139. Awn arising at the very tip of the lemma, either between 2 teeth, or simply as a projection or prolongation from a toothless lemma 140
140. No teeth at tip of lemma, the awn extending from the tip itself 3. FESTUCA
140. Lemma 2-toothed or lobed at tip 141
141. Leaf-sheaths normal, open; branches of inflorescence erect or ascending, mostly unbranched; spikelets very short-stalked, scattered or crowded, more or less parallel the length of branch; awn 1 mm. or less long 8. DIPLACHNE
141. Leaf-sheaths unusual, closed; branches of inflorescence mostly spreading or drooping; spikelets long-stalked, not paralleling the length of branch; awn usually 2-50 mm. long 2. BROMUS
139. Awn arising from the back of the lemma on at least one of the florets, either just below the tip or at or below the middle 142
142. Lemma tapering to a tip without teeth 32. ARRHENATHERUM
142. Lemma 2-toothed at the tip 29. TRisetum
133. No awn present on any part of spikelet (hairs attached to or covering parts of the spikelet should not be judged here as awns) 143
143. Spikelets consisting of staminate (male) florets only 7. ERAGROSTIS REPTANS (staminate plant)
143. Spikelets with the stamens and pistil in the same floret in most or all the florets present 144
144. Spikelets conspicuously crowded and overlapping, and in bunched groups of dense 1-sided clusters 145
145. Leaf-blades 7-8 mm. broad; glumes shorter than lemmas; glumes and lemmas hairy 12. DACTYLIS
145. Leaf-blades mainly 10-20 mm. broad; glumes longer than lemmas; glumes and lemmas glabrous 59. PHALARIS ARUNDINACEA
144. Spikelets obviously scattered on the branches, or if appearing crowded or overlapping then not in bunched groups of dense 1-sided clusters 146
146. Lemmas either minutely 2-toothed or with 3 minute projections (extensions of the 3 nerves above the rounded tip) at summit (do not judge the irregularly edged and sparsely fringed rounded summit of the lemma in *Puccinellia distans* as teeth) 147
147. Three minute projections from the top of the rounded lemma present; spikelets usually reddish-purple, maroon, or dark wine-colored (yellow-green in a rare form); ligule a band of hairs 0.5-1 mm. long with an outer tuft of hairs on each side at the base of leaf-blade 16. TRIDENS
147. Two minute triangular teeth or lobes at the tip of the lemma (use magnifying lens to see either conspicuous or very minute teeth); ligule chiefly a membranous border or an irregularly cut appendage, but hairs, if present, an inconspicuous part of ligule 148
148. Spikelets 5-11-flowered 149
149. At least the upper leaf-sheaths closed at summit 2. BROMUS
149. Leaf-sheaths all open 3. FESTUCA
148. Spikelets 2-3-flowered 150
150. Glumes 20 mm. or more long; leaf-sheaths normal, open at the overlapping margins 31. AVENA
150. Glumes 5-8 mm. long; leaf-sheaths unusual, closed at the margins 15. MELICA
146. Lemma with a simple pointed or rounded tip or the tip rounded and irregularly edged and fringed 151
151. Cobwebby hairs at base of lemma (pull off parts above the first 2 glumes to see) 6. POA
151. No cobwebby hairs present at base of lemma 152
152. Leaf-blades 10-25 mm. wide; spikelets very conspicuously flattened, 1-2 cm. wide 11. UNIOLA
152. Leaf-blades 2-12 mm. wide; spikelets, if flattened, at most 8 mm. wide 153
153. Leaf-sheaths of at least the upper leaves closed at summit 154
154. Spikelets 3-12-flowered; all spikelets of about the same size and shape, all perfect 5. GLYCERIA

- 154. Spikelets 2-3-flowered; the uppermost floret distinctly smaller and different in size and shape (it is sterile) 15. MELICA
- 153. Leaf-sheaths all open 155
- 155. At least the second glume broadest in the upper half; spikelets 2-3-flowered 28. SPHENOPHOLIS
- 155. The glumes broadest at the base or in the lower half; spikelets usually 2-8-flowered 156
- 156. Lemmas faintly or not at all nerved, or with at most three prominent nerves 157
- 157. Lemmas with 3 prominent or weak nerves 7. ERAGROSTIS
- 157. Lemmas with 5 very faint nerves or with only the main keel showing 158
- 158. Lemmas short- to long-pointed (acute to acuminate) 3. FESTUCA
- 158. Lemmas rounded or flat-topped at summit 4. PUCCINELLIA
- 156. Lemmas prominently 5-9-nerved 159
- 159. Leaf-sheaths of at least the upper leaves closed; lemma rounded (convex) on the back. 5. GLYCERIA
- 159. Leaf-sheaths all open; lemma keeled on the back (a nerved ridge in the center) 160
- 160. Spikelets V-shaped, broadest above the middle; lemmas and palea firm and rigid; stamen 1; lower lemma empty 11. UNIOLA LAXA
- 160. Spikelets oblong- to ovate-lanceolate, broadest at the base or in the lower half; stamens 3; florets all perfect 6. POA

Tribe I. BAMBUSEAE

Grasses of this tribe have the culms woody, at least at the base, usually hollow, and are always perennial. The leaf-blade is flat, frequently broad, jointed and petioled with the leaf-sheath. The spikelets are 2- to several-flowered, and the lodicules are conspicuous. The rachilla is articulated above the glumes.

1. *Arundinaria* Michx. Cane

Arundinaria gigantea (Walt.) Chapm. Map 104
 Flowers April-May; in some years apparently not at all flowering.
 Southern Missouri northeast to Perry, Madison, and Reynolds counties. Common in the lowlands and along the larger streams of the Ozarks of the south-eastern part of the state; moist places on limestone glades, on and at the base of limestone bluffs and along the White River and tributaries in southwestern Missouri. Vast acreage once covered by the cane along White River and tributaries has now been

inundated by the creation of the high Table Rock, Bull Shoals, and Norfork dams.
 Ranges from Florida and Texas, north to Delaware, Ohio, Indiana, Illinois, and Missouri.
 Often forming canebrakes difficult of penetration. The flowering stem has few or no leaves. The young shoots are sometimes cooked and eaten, and the mature grains (at the rare intervals when produced) are also eaten. The young parts especially of the plants furnish forage for livestock. Baskets, mats, pipstems, and fishing poles are made from the culms.

Tribe II. **FESTUCEAE**

Grasses of this tribe have 2—many perfect flowers, the glumes are usually shorter than the lowermost floret, the awns on the lemma, when present, start from the tip or from between terminal teeth of the lemma, and the rachilla is usually articulated above the glumes.

2. Bromus L. Brome Grass

Most species of this genus shed relatively little pollen and are regarded as unimportant in hay fever.

- a. At least the upper leaf-sheaths glabrous *b*
- b. Branches of inflorescence widely spreading to drooping; lemmas more or less hairy; woodland plants *c*
- c. Leaf-sheaths closed or nearly closed at summit, overlapping, covering 4 or more of the nodes (joints) of the culm; the sheaths densely hairy at their summit and with conspicuous horizontal spreading flanges and auricles (ear-like outgrowths); nerves of lemma rather prominent below the middle 4. *B. LATIGLUMIS* f. *LATIGLUMIS*
- c. Leaf-sheaths V-shaped at summit, not overlapping and covering only 1–2 (rarely 3) nodes, the other nodes exposed; the sheaths not densely hairy at their summit and without any horizontal spreading flanges or auricles; nerves of lemma faint or inconspicuous below the middle 3. *B. PURGANS* f. *LAEVIVAGINATUS*
- b. Branches of inflorescence ascending to nearly erect; lemmas glabrous or nearly so, at least not short-hairy; plants of open places *d*
- d. First glume 1-nerved; creeping rhizomes present 2. *B. INERMIS*
- d. First glume 3–5-nerved; no rhizomes present *e*
- e. Spikelets strongly flattened with keeled lemmas, 20–38 mm. long; lemmas closely overlapping; rachilla of spikelet not exposed at maturity; lemma without any conspicuous hairy (ciliate) margin 1. *B. CATHARTICUS*
- e. Spikelets rather plump, the lemma more or less rounded on the back, 10–20 mm. long; lemmas with margins folding in and exposing rachilla of spikelet at maturity; fringe of hairs (ciliate) on margin of palea conspicuous and projecting at maturity (seen on very mature spikelet) 5. *B. SECALINUS*
- a. Most or all of leaf-sheaths hairy *f*
- f. Awns 12–50 mm. long, longer than their lemmas themselves *g*
- g. Awns 30–50 mm. long; lemma 25–32 mm. long; 2nd glume 24–30 mm. long 10. *B. RIGIDUS*
- g. Awns 10–30 mm. long; lemmas 10–22 mm. long; 2nd glume 8–18 mm. long *h*
- h. Awns 20–30 mm. long; spikelets 4–5 cm. long (including awns); lemmas 16–22 mm. long; 2nd glume 13–18 mm. long 11. *B. STERILIS*
- h. Awns 10–17 mm. long; spikelets 2–3.5 cm. long (including awns); lemmas 10–12 mm. long; 2nd glume 8–10 mm. long 12. *B. TECTORUM*
- f. Awns none or up to 12 mm. long, shorter than their lemmas themselves *i*
- i. Glumes and lemmas rather conspicuously hairy *j*
- j. Plants of open places and waste ground; branches of inflorescence erect or strongly ascending, the pedicels (stalks of spikelets) mostly shorter than the spikelets; lemmas with prominent nerves 6. *B. MOLLIS*
- j. Plants of woodland; branches of inflorescence at first erect, eventually widely spreading or drooping, the pedicels either longer than or about equaling length of spikelet; lemmas without prominent nerves *k*
- k. Leaf-sheaths closed or nearly closed at summit, overlapping, covering 4 or more of the nodes (joints) of the culm; the sheaths hairy at their inside summit and with conspicuous horizontal spreading flanges and auricles (ear-like outgrowths); nerves of lemma rather prominent below the middle 4. *B. LATIGLUMIS* f. *INCANUS*
- k. Leaf-sheaths V-shaped at summit, not overlapping and covering only 1–2 (rarely 3) nodes, the other nodes exposed; the sheaths not hairy at their inside summit and without

Plate no. 16. 1. *Arundinaria gigantea*; a. Flowering shoot, $\times \frac{3}{8}$; b. Summit of culm sheath, outer and inner face, showing auricles and ligule, $\times 1\frac{1}{2}$; c. any horizontal spreading flanges or auricles; nerves of lemma faint or inconspicuous below the middle 3. *B. PURGANS* f. *PURGANS*

i. Glumes or lemmas glabrous or nearly so, the hairs if present very short and inconspicuous 1

l. Branches of the inflorescence erect or ascending, more or less straight; use magnifying lens to note that hairs on leaf-sheaths are straight and rather evenly spaced and not dense enough to present a whitish appearance. 7. *B. RACEMOSUS*

l. Branches of the inflorescence widely spreading to drooping, rather flexuous (wavy or curved alternately in opposite directions); use magnifying lens to note that hairs on leaf-sheaths are backward-pointing, curved or tangled towards tip and dense, giving a matted whitish appearance of soft hairs m

m. Awn strongly slanting or arching or spreading; anthers 1 mm. long 8. *B. SQUARROSUS*

m. Awn straight to slightly spreading; anthers 1-4 mm. long 9. *B. JAPONICUS*

1. *Bromus catharticus* Vahl Rescue Grass

Map 105

Flowers late April-July.

Known from Jackson County, where introduced at Sheffield (May 28, 1904, *Bush 1957*), St. Louis, and Jasper (open waste ground, Stockyard Switch, Joplin, April 30, 1957, *Palmer 64896*) counties.

Native to South America. Cultivated in the southern United States as an early winter and spring pasture, escaped and naturalized north to New York, Missouri, and Kansas.

A cathartic action is ascribed to the plant.

2. *Bromus inermis* Leyss Smooth Brome,

Hungarian Brome

Map 106

Flowers late May-July.

Introduced along roadsides, in fields, and waste ground, where common in northern, central, and western Missouri; mostly absent at present throughout the Ozark section.

A native of Europe, which ranges in North America from Newfoundland to British Columbia, south to Virginia, Ohio, Missouri, Kansas, and New Mexico.

This grass is successfully planted in this country for its value in pasturage and hay-production. Each year it is becoming increasingly common as a roadside waif.

By Wagnon the Missouri material is treated as *B. inermis* subsp. *inermis* (Leyss.) Wagnon.

3. *Bromus purgans* L.

Map 107

Flowers late May-early July.

A native woodland species of rich or rocky ground, grassy thickets along streams, and wooded bluffs and talus, especially limestone. Typical *B. purgans* f. *purgans* is found throughout Missouri. *B. purgans* f. *laevivagatus* Wieg., with glabrous leaf-sheaths and blades, occurs in several counties in southern Missouri.

Ranges from Quebec, New England, and Alberta, south to Florida, Louisiana, Texas, and Arizona.

This and the following species (*B. latiglumis*) are the only native species found in the state, the others all being introduced from Europe or South America.

Purgative qualities are ascribed to this species.

According to Wagnon (Rh. 52: 211-15. 1950) this species should receive the name *B. pubescens* Muhl. ex Willd.

PLATE NO. 17

109 *Bromus secalinus* (Chess)110 *Bromus mollis* (Soft Chess)111 *Bromus racemosus* (Hairy Chess)

4. ***Bromus latiglumis*** (Shear) Hitchc. Map 108
Flowers July and August.

Rich wooded slopes and bluffs, usually in limestone areas, where rarely collected in parts of eastern, northern, and central Missouri where represented as *B. latiglumis* f. *latiglumis*. The form with pilose leaf-sheaths, *B. latiglumis* f. *incanus* (Shear) Fern., known by a single collection from Jackson County (uncommon, Little Blue, Aug. 9, 1896, *Bush* 396), has been identified by Wagnon as typical *B. latiglumis* f. *latiglumis*.

According to Wagnon, material identified as *B. latiglumis* = *B. purgans* L., whereas material previously called *B. purgans* = *B. pubescens* Muhl. ex Willd. (Rh. 52: 211-15, 1950).

5. ***Bromus secalinus*** L. Chess Map 109
Flowers principally May-early July.

Introduced in fields, limestone glades, prairies, roadsides, railroads, and waste places throughout Missouri.

Native to Europe and spread throughout much of the United States north into Quebec and British Columbia.

6. ***Bromus mollis*** L. Soft Chess Map 110
Flowers May and June principally.

Occurs along railroads and cultivated ground. Known only from St. Louis and Jackson (*Bush*, June 5, 1891) counties.

Native of Europe, and introduced in North America from Newfoundland to British Columbia, south to North Carolina, Indiana, Illinois, Missouri, Kansas, Utah, and California; most abundant in the Pacific states.

This grass is planted for its spring forage value. The perennial *B. inermis* is regarded as superior to

this annual brome from the standpoint of a cover and forage crop.

7. ***Bromus racemosus*** L. Hairy Chess Map 111
Bromus commutatus Schrad. [G, P & S]
Flowers principally late May-July.

Occurs in fields, waste ground, along roadsides, and railroads throughout Missouri.

Native of Europe; introduced into the United States from the Atlantic to the Pacific Coast and north into Nova Scotia and British Columbia.

Material identified previously as *B. racemosus* L. and *B. commutatus* Schrad. is placed together here, as the two are scarcely separable as species. The present treatment agrees with that of Gleason (New Illustrated Flora, p. 105). He maintains that the form having longer lemmas (9-11 mm. long) and larger panicles with more numerous spikelets, known as *B. commutatus*, is more abundant in North America than the one (*B. racemosus*) having smaller lemmas (about 7 mm.) and smaller panicles with fewer spikelets.

8. ***Bromus squarrosus*** L. Chess Map 112
Flowers June-July.

In Missouri known only from St. Louis County (St. Louis, along the Terminal R. R. Assoc. track between Rutger Street and the control at Carroll St., June 17, 1956, *Muehlenbach* 954).

Native of Europe; introduced in the United States locally from Connecticut to Michigan and North Dakota to Missouri.

9. ***Bromus japonicus*** Thunb. Japanese Chess, Japanese Brome Map 113
Bromus arvensis [of G, P & S], not L.
Flowers late May-July.

Occurs in fields, waste ground, and along roadsides throughout Missouri.

3
PLATE NO. 18

112 *Bromus squarrosus* (Chess)113 *Bromus japonicus* (Japanese Brome)114 *Bromus rigidus* (Ribgut Grass)

Introduced from Europe; naturalized throughout most of the United States from Vermont to Washington, south to Florida, Texas, and California.

This is a palatable grass, which often appears in overgrazed range land, and early in the spring offers temporary pasture.

All the Missouri material, previously identified as *B. arvensis*, is here treated as *B. japonicus*. *Bromus arvensis* L. is known only from a few states in the United States, and may be recognized principally by having the lemma as long as the palea.

Bromus japonicus, var. *porrectus* Hack., with straighter awns, has been collected in Pike County (along road in alfalfa field, June 24, 1947, *Etter 337*). However, it is not maintained in the present treatment as distinct, and seems better regarded as synonymous with typical *B. japonicus*.

10. ***Bromus rigidus* Roth.** Ribgut Grass Map 114
Flowers May–July.

Found in waste ground and along railroads, where it has been found only in St. Louis (Bremen Avenue freight yard of the Terminal Railroad, St. Louis, May 30, 1955, *Muehlenbach 614*) and Jackson (Courtney, July 1, 1904, *Bush 2067*) counties.

Native of Europe; introduced into the United States, where very common in the Pacific states, but in the eastern half known locally from Massachusetts to Maryland, and Mississippi.

In the Pacific states this grass is believed to be a contributing factor in causing hay fever. The plant owes its common name from the effect produced by the long and strong awns of the lemmas, which can give bad lacerating wounds to sheep and other grazing animals.

11. ***Bromus sterilis* L.** Map 115
Flowers May and June.

Open or rocky ground, frequently along streams,

where known only in southwestern Missouri from Newton (open ground along brook, George Washington Carver National Monument, near Diamond, May 19, 1956, *Palmer 62347*, and May 31, 1957, *Palmer 65392*), Polk (open ground between roadway and river, near Burns, May 23, 1957, *Palmer 65293*), and Wright (open rocky valley of Dove Creek, T30N, R13W, SE $\frac{1}{4}$ sect. 15, $3\frac{1}{4}$ mi. ESE of Rayborn, May 6, 1957, *Steyermark 84097*) counties.

Native of Europe; introduced into the United States from Massachusetts and Ontario south to North Carolina, Alabama, Arkansas, Colorado, and California.

Like *B. rigidus*, the awns of this species also penetrate and cause damage to the soft facial tissues of sheep and other grazing animals.

12. ***Bromus tectorum* L. var. *tectorum*** Map 116
Downy Chess
Flowers April–early June.

Common in fields, waste ground, along roadsides, and railroads, throughout Missouri.

Native of Europe; introduced throughout most of the United States.

This is the most common of the introduced species in Missouri and elsewhere, and comes into flower earlier than any of the other species. The inflorescences with their drooping green or reddish-purple or rose-tinted spikelets produce a striking color effect in early spring along the secondary roads and highways, where they occur usually in dense stands.

The long awns of this species easily penetrate the mouth parts or eyes of grazing sheep, cattle, and horses, causing mechanical injuries, and are especially troublesome among sheep in the Rocky Mountain states.

The form with glabrous spikelets, *B. tectorum* var. *glabratus* Spenner, should eventually be found in the state.

115 *Bromus sterilis*

116 *Bromus tectorum* (Downy Chess)

117 • *Festuca octoflora* var. *octoflora* (Six-weeks Fescue)
117 □ *Festuca octoflora* var. *glauca*
117 x *Festuca octoflora* var. *tenella*

Excluded species

Bromus breviaristatus Buckley.

This species was cited from Jackson County in

Palmer & Steyermark's Annotated Catalogue. It was based upon a specimen collected by Bush (4961 from along railroad, Sheffield), but this specimen is now identified as *B. inermis* Leyss.

3. **Festuca** L. Fescue

Several species of this genus are known to cause hay fever.

- a. Leaf-blades flat, 4 mm. or more wide b
- b. Leaf-blades with ear-like extensions (auricles) at base by junction with sheaths; spikelets 8-15 mm. long; lemmas 5.5-10 mm. long; branches of inflorescence (panicle) bearing spikelets nearly to the base 4. *F. ELATIO*
- b. Leaf-blades without ear-like extensions (auricles) at base by junction with sheaths; spikelets 4-8 mm. long; lemmas 3-5.5 mm. long; branches of inflorescence bearing spikelets above the middle c
- c. Spikelets lanceolate to elliptic, 1-5 flowered, (usually 2-3) scattered and not overlapping at least along the lowest branches of inflorescence; lemmas and palea acute or nearly acute . 5. *F. OBTUSA*
- c. Spikelets ovate, 3-6-flowered, rather densely clustered and overlapping at least along the lowest branches of inflorescence; lemma and palea obtuse (blunt at tip) 6. *F. PARADOXA*
- a. Leaf-blades hair-like or thread-like, or very narrow, usually with the margins rolled in, 0.5-3 mm. wide, or if flattened, then at most 3 mm. wide d
- d. Perennial plants with numerous crowded leaves at the base, and with the remains of the old leaf-sheaths at the base; culms (stems) usually several from a dense leafy clump; anthers 3 in each floret e
- e. Leaf-sheaths at base of plant thin, reddish or purple, breaking up into shreds with the strong veins persisting as fibers; anthers 1/2-2/3 lengths of palea 7. *F. RUBRA*
- e. Leaf-sheaths at base of plant firm, whitish or grayish, persistent and not breaking up into shreds; anthers 1/4-1/2 length of palea 8. *F. OVINA*
- d. Annual plants with but few leaves or leaf-sheaths at the slender base; culms (stems) solitary or very few in a small tuft; anther 1 (rarely 3) in each floret f
- f. Awn of lemma 9-14 mm. long; 1st glume 1-1.9 mm. long, 1/4-1/3 the length of the 2nd glume; 2nd glume 4-5 mm. long 3. *F. MYUROS*
- f. Awn of lemma 1-9 mm. long; 1st glume 2 mm. long, 2/3-3/4 the length of the 2nd glume; 2nd glume 3.5 mm. long g

120 □ *Festuca elatior* var. *arundinacea*

and hair like culms, or simply the culms themselves, persist in the dried state during summer and fall as delicate pale to tawny-brown erect stems. The common name of this species refers to the relatively short span of life, seed formation taking place in about six weeks from time of germination of seed.

The Missouri material falls into three varieties:

- a. Longer awns of lemmas 3.5–7 mm. long . . .
ia. *F. OCTOFLORA* var. *OCTOFLORA*
- a. Longer awns of lemmas up to 3 mm. long . . . b
b. Awns 1–3 mm. long; 1st glume 2.3–4 mm.
long . . . 1b. *F. OCTOFLORA* var. *TENELLA*
- b. Awns at most 2 mm. long or none; 1st glume
1.5–3 mm. long. 1c. *F. OCTOFLORA* var. *GLAUCA*

1a. ***Festuca octoflora* var. *octoflora*** Map 117

Festuca octoflora [of P & S]

Festuca octoflora var. *aristulata* Torr. ex Dewey [BB]

Vulpia octoflora (Walt.) Rydb. [G]

Frequently on sandstone, granite, or chert glades in the Ozark section; also on acid, sterile, and thin soils of dry open woods and slopes, prairies, fields, and leached waste ground. Mostly confined to the Ozark section, north locally to Carroll County.

Ranges from Florida and Texas, north to New Jersey, Illinois, Missouri, and Oklahoma.

1b. ***Festuca octoflora* var. *tenella*** (Willd.)

Fern.

Map 117

Vulpia octoflora var. *tenella* (Willd.) Fern. [G]

Same habitats as var. *octoflora*. This is the commonest variety in Missouri, occurring in most counties of the state. Of expected occurrence eventually in northwestern counties, where as yet not recorded.

Ranges from Georgia, Texas, Colorado, and California, north to Maine, Quebec, and British Columbia.

1c. ***Festuca octoflora* var. *glauca*** (Nutt.) Fern.

Map 117

Vulpia octoflora var. *glauca* (Nutt.) Fern. [G]

Same habitats as the preceding varieties.

Throughout the Ozark region and northwest locally in Carroll and Clinton counties.

Ranges from Florida and New Mexico, north to Missouri, Wisconsin, South Dakota, and Wyoming.

The three varieties of *F. octoflora* intergrade in length of awns and measurements of glumes and lemmas, and are maintained in the present treatment for convenience in naming extremes of variation.

The varieties of *F. octoflora* often have inflorescences which show more branching with shorter lateral branches than shown by either *F. sciurea* or *F. myuros*. The last two species usually have a longer and more continuous inflorescence.

2. ***Festuca sciurea* Nutt.**

Map 118

Vulpia Elliothea (Raf.) Fern. [G]

Flowers April–June.

Mostly in sandy soils and fields in southeastern Missouri and rocky open ground westward in Douglas and Jasper counties.

Ranges from Florida to Texas, north to New Jersey, Maryland, Missouri, and Oklahoma.

3. ***Festuca myuros* L.**

Map 119

Vulpia myuros (L.) K. C. Gmel. [G]

Flowers mid-April–June, the spikelets maturing as late as July.

Waste ground and along railroads, where known from St. Louis, Boone (University of Missouri South Farm, 5 mi. south of Columbia, July 10, 1947, *R. B. Livingston*), and McDonald (open ground around artificial pond near Pineville, June 5, 1957, *Palmer 65531*,

126 *Puccinellia airoides* (Alkali Grass)

sheaths parallel to the main axis, whereas in *F. rubra* var. *rubra* and other varieties the young shoots grow out from the main axis and break through the sheath at its base.

Plants generally have a gray-green color. Since they form dense bumpy tufts, they are not a desirable lawn grass, as is Chewings Fescue (*F. rubra* var. *commutata*).

4. *Puccinellia* Parl. Alkali Grass

Lemmas broadly rounded or truncate at the summit, broadest near the tip, the margin (under a lens) with a minute fringe of teeth; lower branches of inflorescence usually downward spreading; ligule 0.5–1.5 mm. long 1. *P. DISTANS*

Lemmas somewhat pointed or tapering at the tip, the margin (under a lens) with minute irregular teeth; lower branches of inflorescence ascending or spreading horizontally, but not downward; ligule 1.5–2 mm. long 2. *P. AIROIDES*

1. *Puccinellia distans* (L.) Parl. Map 125 Flowers May–June.

Known only from St. Louis County (100–200 meters north of Municipal Bridge between the right-of-way of the Terminal Railroad and the Mississippi River levee, St. Louis, May 23, 1954, *Muehlenbach* 70).

Native of Europe; naturalized in North America from New Brunswick to Delaware, inland to Ontario, Michigan, Illinois, Wisconsin, and Missouri.

2. *Puccinellia airoides* (Nutt.) Wats. & Coult. Map 126 Alkali Grass *Puccinellia Nuttalliana* (Schultes) Hitchc. [G, BB] Flowers May–July.

Known only from St. Louis County (Carrie Avenue freight yards of Terminal Railroad Assoc., St. Louis, June 1, 1957, *Muehlenbach* 1179).

Ranges from British Columbia and the Yukon to Wisconsin, Minnesota, Texas, New Mexico, and California; introduced east in Maine, Vermont, New York, Ontario, and Missouri.

5. *Glyceria* R. Br. Manna Grass

The name Manna Grass refers to the use made of several European species, the seeds of which furnish a flour. It is reported that in Europe, a flour made from *Manna Seeds*, by which the seeds are known, provides the constituents of a tasty and nutritive bread. The seeds are also used as a thickening in soups and gruels. It is reported also, that geese fatten quickly when fed on grain from various species of this genus. Most species provide good forage.

Most of the species inhabit the water. The spikelets easily fall from the inflorescence when handled.

1. ***Glyceria acutiflora* Torr.**

Map 127

Flowers early May–July.

In Missouri this plant is exclusively confined to natural upland sink-hole ponds of the southern Ozarks north to Dent and Laclede counties, east to Reynolds and west to Webster and Taney counties. It always grows directly in the water.

Ranges from Maine to Michigan, south to Delaware, West Virginia, Indiana, Tennessee, and Missouri.

2. ***Glyceria septentrionalis* Hitchc.**

Floating Manna Grass

Map 128

The following two varieties were distinguished above in the key to species:

2a. ***Glyceria septentrionalis* var. *septentrionalis***

Map 128

Glyceria septentrionalis [of P & S, G]

Flowers late May–September.

Frequents sink-hole ponds, borders of sloughs and oxbow lakes in alluvial wooded bottoms, and swampy ground at the base of river bluffs. Rather local and

scattered in northern, eastern, and central Missouri; absent from most of the Ozark section.

Ranges from Massachusetts to Ontario, south to Georgia, Kentucky, Missouri, and Texas.

2b. ***Glyceria septentrionalis* var. *arkansana***

(Fern.) Steyermark & Kucera

Map 128

Glyceria arkansana Fern. [G, P & S]

Flowers May–July.

Occurs along sloughs and swampy ground principally in the lowland section of southeastern Missouri.

Ranges from New York to Illinois, south to Louisiana and Arkansas; also in Virginia.

3. ***Glyceria striata* (Lam.) Hitchc.**

Fowl Meadow Grass

Map 129

The Missouri material may be divided into two varieties:

Commonly encountered; lemmas scarcely or inconspicuously scarious-tipped; branches of inflorescence widely spreading or even turning down in age; spikelets greenish or purplish

3a. *G. STRIATA* var. *STRIATA*

Rarely encountered; lemmas with conspicuous, broad, scarious (thin, whitish, or transparent) tips; branches of inflorescence stiffer, more ascending; spikelets purple, rarely green . . .

3b. *G. STRIATA* var. *STRICTA*

3a. *Glyceria striata* var. *striata* Map 129

Flowers May-July.

Common in wet woods, along streams, borders of ponds, drainage-ditches, sloughs, and wet depressions in prairies. Throughout Missouri.

Ranges from Newfoundland to Alberta, south to Florida, Alabama, and Texas.

3b. *Glyceria striata* var. *stricta* (Scribn.)

Fern.

Map 129

Known only from Dade County (wet ground in woods along Sons Creek, 4 mi. north of Greenfield, June 10, 1951, *Palmer 52200*).

This variety has a more northerly range, extending from Labrador to Alaska, south to New York, Illinois, Iowa, Missouri, South Dakota, and northern Mexico.

4. *Glyceria pallida* (Torr.) Trin.

Pale Manna Grass

Map 130

Flowers May-June.

Known from swamps in Scott and Butler counties in southeastern Missouri, and in cold water of Yancy Mills Spring, Phelps County (Nov. 28, 1936, *Steyermark 20914*).

Ranges from Nova Scotia and Maine to Ontario, south to Virginia, Tennessee, and southeast Missouri.

6. *Poa* L. Blue Grass

Members of this genus are important for their forage value, many of them being nutritious and furnishing valuable food for livestock.

Some of the species cannot be properly determined without use of a high-power lens. This facilitates seeing the marginal and intermediate nerves and their pubescence, characters of importance used in distinguishing some of the species. The marginal nerves may be glabrous or pubescent. The intermediate nerves, which are located between the marginal nerves and midrib, may be strong or very faint, and glabrous or pubescent. Most species of *Poa* have 2 or more florets, but in those rare individuals having only 1-flowered spikelets, the tuft of wool at the base of the lemma is sufficient to identify the plant as a *Poa*.

- i. Ligule conspicuous, 2–5 mm. long; inflorescence rather narrowly pyramidal or somewhat cylindric; spikelets usually with some touch of bronze or purplish; lemma of firm texture, with 3 noticeable nerves, the other (intermediate) nerves obscure 9. *P. PALUSTRIS*
- i. Ligule only 1–2 mm. long; inflorescence oblong-pyramidal or broadly pyramidal; spikelets silvery or pale green; lemma of soft thin texture, with 5 distinct nerves (including the ones along the very margins) 6. *P. SYLVESTRIS*

1. ***Poa Chapmaniana*** Scribn. Chapman
 Blue Grass

Map 131

Flowers April–May.

Fallow and sandy open fields, rocky glades of sandstone, chert, or granite, prairies, openings in dry sterile woods, along dry roads, and in waste ground, mostly in acid soils. Most common in southern and central Missouri, north in fallow fields and openings in dry acid woodlands to Nodaway, Gentry, Linn, Shelby, and Pike counties.

Ranges from Florida to Texas, north to Delaware, Indiana, Iowa, and Kansas.

This grass ordinarily grows in drier sites than *P. annua* and dries up sooner. The culms are usually more erect and the inflorescence is narrower and more contracted than in *P. annua*, and turns brownish more quickly. In fallow fields *P. Chapmaniana* is often found associated with *Cardamine parviflora* var. *arenicola*, *Festuca octoflora* var. *tenella*, *Myosurus minimus*, and *Chaerophyllum procumbens*, and on sandy glades or openings in dry upland woods it is more frequently

associated with *Festuca octoflora* var. *tenella* and *Cardamine parviflora* var. *arenicola*.

2. ***Poa annua*** L. Annual Blue Grass Map 132
 Flowers February–December.

The common variety encountered, *P. annua* var. *annua* is annual, and occurs in gardens and lawns around dwellings, in pastures, fields, waste places, along paths, and streams, and in disturbed sections of woodland. Although undoubtedly it is present in every county of the state, it has been recorded actually only from the counties of southern and central Missouri north to Pike, Boone, and Jackson counties.

Introduced from Europe; ranging throughout the United States north to Labrador and Alaska.

Two other variations of *Poa annua*, which are perennial in habit, have been found in Missouri. Such plants grow partly or completely submerged in cold running waters of the spring branches, or produce creeping stems which root at the nodes in the gravel of spring branches in the Ozark section of the state,

Plate no. 21. 1. *Glyceria striata*; a. Plant, $\times \frac{3}{8}$; b. Spikelet, $\times \frac{3}{4}$; c. Floret, $\times \frac{7}{16}$. 2. *Glyceria pallida*; a. Plant, $\times \frac{3}{4}$; b. 133 *Poa compressa* (Canada Blue Grass)134 *Poa pratensis* (Kentucky Blue Grass)

135 Excluded species

and appear very different from ordinary *P. annua* var. *annua*. A collection from Steelville Spring, at Steelville, Crawford County (Steyermark 6638) has been identified as *P. annua* var. *aquatica* Aschers. It has a delicate and lax habit with greatly prolonged culms characteristic of this variety. The other variety encountered, *P. annua* var. *reptans* Haussknecht, with greatly elongated prostrate culms, which root at the nodes, appears to be commoner, and occurs in springs and spring branches in a number of counties of southern and central Missouri north to St. Louis, Boone, and Jackson counties. These varieties do not appear to be well marked. Both variations may be found in the partly or completely submerged state in spring water, and transitional variations occur which might be classified either as one or the other of the two perennial types. For a discussion of the aquatic varieties and their localities in Missouri, see Steyermark (Rhodora 43: 630-32, 1941).

Forty-one varieties (besides subvarieties and forms) of *P. annua* have been described. For a discussion of these the reader is referred to Ascherson, P. and P. Graebner, Synopsis der Mitteleuropäischen Flora 2, part 1: 388-90, 1921.

3. *Poa compressa* L. Canada Blue Grass

Map 133

Flowers May-August.

Occurs throughout the state in various types of soils in dry fields, pastures, waste ground, prairie openings, grazed open woodland, and along roadsides, railroads, and rocky ground. It is absent generally from wet places and dense woodland.

Native of Europe; introduced into North America, where found nearly throughout, from Newfoundland and Alaska, south to Georgia, Oklahoma, New Mexico, and California.

Canada Blue Grass is cultivated for pastures in poor soil, but is inferior to the Kentucky Blue Grass. It is being used as a grass on athletic and polo fields, where it can be cut infrequently and as high as 3-4 inches. The large amount of pollen shed by Canada Blue Grass makes it a serious cause of hay fever during the months especially from June to August.

This species sometimes causes considerable confusion in identification because of its variability with respect to the number of florets per spikelet and length of spikelet. Most manuals describe the spikelets as 3-6-flowered, and 4-6 mm. long. However, the spikelets may have as many as 9 flowers and attain 7-8 mm. in length, as in the collection of Steyermark 85320 from Mercer County. The eighth edition of *Gray's Manual* (p. 117) correctly accounts for such extremes of variation, giving the spikelets as '3-6 (-9)-flowered, 3-8 mm. long.'

4. *Poa pratensis* L. Kentucky Blue Grass

Map 134

Flowers chiefly May-July.

Found throughout Missouri in fields, meadows, rocky glades, open woodland, along river banks, and in waste ground.

Ranges throughout the United States, north to Labrador and Alaska. Some botanists consider most of the Kentucky Blue Grass which is found in the United States as an introduction from Europe, with the possibility of its being native in Canada and the northern United States. Other botanists believe the grass to be mainly a native one, particularly in the northern half of the United States, but introduced as a cultivated species in the southern United States.

Kentucky Blue Grass is the chief lawn grass in the cooler and moister climates of the northern half of the

PLATE NO. 22

136 *Poa trivialis* (Rough Blue Grass)137 *Poa sylvestris* (Sylvan Blue Grass)138 *Poa Wolfii*

United States. Some recent superior grass strains, such as Merion Blue Grass, a variety discovered on the Merion Golf Course near Philadelphia, have been developed from Kentucky Blue Grass. It is also considered one of the best pasture grasses.

Together with Orchard Grass (*Dactylis glomerata*), Kentucky Blue Grass accounts for most of the hay fever occurring in the eastern United States during May and June. Some manuals give the spikelet length as 4–5 mm. long, but the spikelets vary in Missouri material from 3–6.5 mm. long. The spikelets are often purplish or tinged with rose-purplish color.

5. ***Poa trivialis* L.** Rough Blue Grass Map 136
Flowers May–June.

Known only from Newton County, southwestern Missouri, where collected in wet, rocky, shaded ground, about Haddock Spring, 3 mi. southwest of Wentworth, May 14, 1955 (*Palmer 59826*). The determination has been made at the United States National Herbarium.

Native of Europe; naturalized in North America from Newfoundland and Ontario to Wisconsin, south to Georgia, Louisiana, and Kansas, and also from Alaska to California.

Some Missouri specimens, previously identified as *P. trivialis*, have proven to be *P. pratensis*. The Palmer collection, here cited, has the retrorsely scabrous sheaths characteristic of *P. trivialis*, but is atypical in having the ligule only 2–2.5 mm. instead of 4–8 mm. long, and in the marginal nerves somewhat pubescent instead of glabrous.

Rough Blue Grass is sometimes used in grass seed mixtures, especially being recommended for meadows and pastures, and in many sections is recommended as a shade grass. It thrives in damp shaded rich soils, where it produces a low-growing grassy cover.

This species is sometimes found to be an important contributing causal agent in hay fever cases.

6. ***Poa sylvestris* A. Gray** Sylvan Blue Grass

Map 137

Flowers late April–June.

This is a common woodland species, occurring throughout the state in lowland woods along streams and river bottoms, as well as on wooded rocky slopes and in rich ravines.

Ranges from New York to Minnesota and Nebraska, south to Florida, Louisiana, and Texas.

After flowering, the lowest branches of the inflorescence become widely spreading to reflexed. The leaves of this species are soft, dark green, and flexible. The plants grow in small individual tufts scattered over the forested ground. The widely spreading panicle branches with rather few pale green spikelets clustered above the middle toward the tips are characteristic. The lemmas vary from sparsely or conspicuously pubescent to nearly glabrous between the nerves.

7. ***Poa Wolfii* Scribn.**

Map 138

Flowers late April–June.

Like *P. sylvestris*, this species favors woodland habitats, and is found in wooded areas along streams, rocky wooded slopes and moist ledges. It is much less commonly collected than *P. sylvestris*, and has been found thus far in southern, central, and eastern Missouri.

Ranges from Virginia, Ohio, and Minnesota to Missouri.

In addition to the larger spikelets, *P. Wolfii* has the lower branches of the panicle only spreading at maturity, and not reflexed as in *P. sylvestris*. Moreover, the lemmas are acute and glabrous between the nerves in *P. Wolfii*, obtuse and often more or less pubescent or rarely glabrous between the nerves in *P. sylvestris*.

8. ***Poa bulbosa* L.** Bulbous Blue Grass Map 139

Flowers April–June.

Known only from Christian County, southwestern Missouri, where introduced in open ground along

Poa nemoralis [of P & S], not L.
Flowers June–September.

Known only from Jackson County, western Missouri, where collected along railroad, Sheffield, June 16, 1896 (*Bush 774*).

Ranges from Newfoundland to Alaska south to Virginia, Ohio, Illinois, Missouri, Nebraska, Colorado, and California; also occurs in Europe and Asia.

The Bush specimen was previously misidentified as *P. nemoralis*.

In *P. palustris* the inflorescence bears numerous spikelets at and beyond the middle of a branch.

Excluded species

***Poa alsodes* Gray.** A specimen collected by Bush (*Bush 13434*), and so labeled by him, from rocky woods, Blue Lick, Saline County, May 2, 1934, has lemmas distinctly 5-nerved with distinct intermediate nerves, and the anthers 1.25 mm. long. It is referred in the present flora to *P. Wolfii*.

***Poa autumnalis* Muhl.** A specimen so labeled was collected by *N. M. Glatfelter* from Meramec Heights, St. Louis County, May 14, 1897. It has the lemmas 4–4.5 mm. long, webbed at base, and glabrous between nerves; the spikelets are 5 mm. long. I have identified it as *P. Wolfii*.

***Poa nemoralis* L.** *Bush 774*, which formed the basis for this determination, is *P. palustris* L.

7. ***Eragrostis* Beauv.** Love Grass

This group of grasses flowers and matures fruit mainly during the summer and autumn months (*Eragrostis poaeoides* may start flowering in late May).

- a. Main stems (culms) creeping and rooting at the nodes (joints) b
- b. Rare species; inflorescence a compact and closely crowded mass of spikelets; spikelets 2–4 mm. wide; flowers with only one sex developed on a single plant, either staminate (male) or pistillate (female); lemmas more or less pubescent (with hairs), 2–4 mm. long; anthers 1.5–2 mm. long 2. *E. REPTANS*
- b. Common species; inflorescence a rather open and loose panicle; spikelets 1.5–2 mm. wide; flowers perfect (both stamens and pistil in the same flower); lemmas glabrous (lacking hairs), 1.5–2 mm. long; anthers 0.2–0.5 mm. long 3. *E. HYPNOIDES*
- a. Main stems (culms) upright to spreading, but not creeping and rooting at the nodes c
- c. Tiny warts or bumps (glands lacking stalks) on margins of leaf-blades and keels (back edge) of glumes and lemmas d
- d. Spikelets mostly 2.5–4 mm. wide; lemmas 2–2.6 mm. long; common species 8. *E. CILIANENSIS*
- d. Spikelets 1.5–2 mm. wide; lemmas 1.7–2 mm. long; rare species 9. *E. POAEOIDES*
- c. No tiny warts or stalkless glands present on leaf margins nor on keels of glumes and lemmas e
- e. Inflorescence narrow and contracted, the branches rather upright and crowded 1. *E. GLOMERATA*

- e. Inflorescence with loosely spreading branches, producing an open appearance. *f*
- f. Inflorescence nodding; leaves mainly at the base of the plant, curved, 6–12 dm. long, long-attenuate 15. *E. CURVULA*
- f. Inflorescence erect; leaves scattered on the stem as well as at the base of the plant, less than 6 dm. long *g*
- g. Mature (fully grown) spikelets at most 1 mm. wide, 5–8 mm. long, 5–15 flowered; lateral nerves of lemma faint or scarcely showing; plant annual with a soft base. 6. *E. PILOSA*
- g. Without the above combination of characters; mature spikelets 1–2.5 mm. wide, but, if only 1 mm. wide, then plants are either perennial with hard or firm bases, or spikelets are usually less than 5 mm. long or less than 5-flowered *h*
- h. First glume 2.5–3 mm. long; at least the lowest lemma 2.5–3 mm. long 13. *E. TRICHODES*
- h. First glume 0.8–2 mm. long; lemmas 1.1–2.5 mm. long. *i*
 - i. No hairs or essentially none on the tiny swelling (pulvinus) at junction of the lowest 2 or 3 main branches with the central axis of the inflorescence. *j*
 - j. Spikelets mostly 6–15-flowered, (4–) 5–8 mm. long; lateral nerves of lemma conspicuous *k*
 - k. Spikelets spreading on pedicels spreading from the main primary branches of the inflorescence; spikelets reddish or rose-purple, 2–2.5 mm. wide; lemma 1.8–2.5 mm. long; 1st glume 1.5 mm. long; seed with a longitudinal furrow extending its whole length *E. MEXICANA* (see excluded species)
 - k. Spikelets rather appressed to and lying along or paralleling the main primary branches of the inflorescence, the pedicels (stalks of spikelets) not spreading; spikelets dull green or lead-colored, sometimes tinged with purplish, 1.3–1.7 mm. wide; lemma 1.5–1.6 mm. long; 1st glume 1 mm. long; seed not longitudinally furrowed 7. *E. PECTINACEA*
 - j. Spikelets mainly 1–5-flowered, 1.4–4 (–5) mm. long; lateral nerves of lemma faint or scarcely showing *l*
 - l. Inflorescence more than 1/2–2/3 height of plant; culms (stems) branched only from the base; leaf-sheaths usually with hairs; most of the pedicels (stalks of spikelets) 5–10 mm. long 4. *E. CAPILLARIS*
 - l. Inflorescence 1/3 to less than 1/2 height of plant; culms (stems) branched at the nodes higher on the plant; leaf-sheaths glabrous (without hairs) except at the summit; pedicels (stalks of spikelets) mainly 1–3 (–5) mm. long. 5. *E. FRANKII*
 - i. Sparse to many hairs on the swelling (pulvinus) at junction of at least the lowest 2 or 3 main branches with the central axis of the inflorescence (junction at the upper branches with the main axis often glabrous) *m*
 - m. Lemmas with conspicuous lateral nerves; spikelets 3– mainly 6–15-flowered; annuals or perennials *n*
 - n. Leaf-blades 4–8 mm. wide; 1st glume 1.2–1.9 mm. long; spikelets rose-purple; plants perennial with a hard base producing pointed buds; culms (stems) simple below the inflorescence; pulvinus at base of branches conspicuously long-pilose. 14. *E. SPECTABILIS*
 - n. Leaf-blades 1–3.5 mm. wide; 1st glume 1 mm. long; spikelets dull green or lead-colored, sometimes tinged with dull purplish; plants annual from a soft base; culms (stems) branched from the nodes below the inflorescence; pulvinus at base of branches sparsely or inconspicuously hairy *o*
 - o. Spikelets rather appressed to and lying along or paralleling the main primary branches of the inflorescence, the pedicels (stalks of spikelets) also appressed, not spreading; lemmas 1.5–1.6 mm. long 7. *E. PECTINACEA*
 - o. Spikelets spreading away from main primary branches of the inflorescence on spreading pedicels; lemmas 1.6–1.8 mm. long 10. *E. ARIDA*
 - m. Lemmas with faint or inconspicuous lateral nerves; spikelets 7–9-flowered; perennials. *p*

Plate no. 23. 1. *Poa bulbosa*, $\times \frac{3}{4}$. 2. *Poa palustris*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$. 3. *Eragrostis capillaris*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$. 4. *Eragrostis hypnoides*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{7}{12}$. 5. *Eragrostis reptans*; a. Pistillate plant (\varnothing), $\times \frac{3}{8}$; b. Staminate plant (σ), $\times \frac{3}{8}$; c. Pistillate floret (\varnothing), $\times \frac{7}{12}$; d. Staminate floret (σ), $\times \frac{7}{12}$. 6. *Eragrostis Frankii*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$. 7. *Eragrostis glomerata*; a. Panicle, $\times \frac{3}{8}$; b. Spikelet, $\times \frac{7}{12}$; c. Floret, $\times \frac{7}{12}$.

PLATE NO. 23

143 *Eragrostis hypnoides* (Creeping Love Grass)144 *Eragrostis capillaris* (Lace Grass)145 *Eragrostis Frankii*

- p. Leaf-blades 4–12 mm. wide (sometimes less than 4 mm.); leaf-sheaths usually conspicuously hispid-pubescent, rarely almost glabrous in one variety; 1st glume 1.5–2 mm. long; spikelets often purplish; fully developed inflorescence 3–9 dm. long. 11. *E. HIRSUTA*
- p. Leaf-blades 1–4 mm. wide; leaf-sheaths glabrous except at hairy summit; 1st glume 1–1.3 mm. long; spikelets usually dull grayish- to brownish-green; fully developed inflorescence 1.5–3.5 dm. long. 12. *E. INTERMEDIA*

1. ***Eragrostis glomerata*** (Walt.) Dewey

This grass has been attributed to Missouri (by Gleason in *New Ill. Fl.* 1: 130. 1952) on the basis of a specimen in the New York Botanical Garden Herbarium with the following information on the label 'Unio itiner. In civitate Missouri. 1837. leg. b. Frank.' No definite locality in Missouri is mentioned by the collector, Frank, but if the specimen were actually obtained in Missouri, it is assumed that it probably originated from some part of the southeastern section of the state, as the species occurs in Arkansas. The range of *E. glomerata* is South Carolina and Arkansas south in the United States to Florida and Texas, southward to Argentina.

2. ***Eragrostis reptans*** (Michx.) Nees Map 142
Flowers August–October.

Sand bars of the Missouri River in Jackson (Courtney, September 21, 1930, *Bush* 11979, 11978, 11973, 11971, 11975, 11976, 11972, 11969; Sept. 5, 1935, 15141), Cass (Pleasant Hill, 1876, *Broadhead*), and Livingston (muddy shores of lake in Grand River bottoms, 3 mi. north of Avalon, Sept. 23, 1955, *Steyermark* 79879) counties are known localities for this rare species.

Ranges from Kentucky, Illinois, Missouri, and South Dakota, south to Tennessee, Louisiana, Texas, and Mexico.

The pistillate inflorescence is dense and somewhat hemispherical in form, whereas the staminate inflorescence is more open and ovoid with fewer-flowered spikelets.

3. ***Eragrostis hypnoides*** (Lam.) BSP.

Creeping Love Grass Map 143
Flowers July–November.

Occurs on margins of ponds, sloughs, and moist, alluvial, usually muddy banks of river, although encountered also on moist sands. Throughout Missouri.

Ranges from southern Quebec throughout most of the United States south to Argentina.

This and the preceding species are creeping annuals. *Eragrostis hypnoides* forms characteristic small-leaved mats along flooded river banks, where it often is the dominant plant present.

4. ***Eragrostis capillaris*** (L.) Nees

Lace Grass Map 144
Flowers July–October.

Common throughout Missouri, except in the northwestern section, where not yet recorded, in fields, recently cleared areas, waste and cultivated ground, rocky open glades, and ledges.

Ranges from Maine to Wisconsin and Iowa, south to Georgia and Texas.

The lower leaf-sheaths and lower part of the culms (stems) are often rose-lavender or purplish. A woolly aphid frequently infests the spikelets of this species. Deam notes this type of aphid on *E. Frankii*.

This annual grass is frequently associated with and sometimes mistaken for *Panicum flexile*, *P. philadelphicum*, and other members of the *Capillare* group, but the normally 2–5-flowered spikelets at once distinguishes the species as belonging in *Eragrostis*.

146 *Eragrostis pilosa* (India Love Grass)147 *Eragrostis pectinacea*148 *Eragrostis cilianensis* (Stink Grass)

5. ***Eragrostis Frankii*** C. A. Meyer var. ***Frankii***
Map 145

Flowers August–October.

Throughout Missouri, but with most of the records thus far from the counties in the central and southern sections of the state, where it occurs on sandbars and mud flats of streams, and in waste and cultivated ground.

Ranges from Quebec to Ontario and Minnesota, south to Florida, Louisiana, and Kansas.

This species is sometimes confused with *E. capillaris*, but the shorter pedicels and compact elongated inflorescence serve to distinguish it from *E. capillaris*.

The var. *brevipes* Fassett, distinguished by having mainly 6–7-flowered spikelets, has not yet been recorded from Missouri.

6. ***Eragrostis pilosa*** (L.) Beauv.

India Love Grass

Map 146

Flowers July–October.

Of infrequent occurrence in Missouri, where it is scattered over the state, occurring on damp muddy or sandy banks along streams, rocky bluffs, and waste ground.

Native of Europe; introduced into the United States from Massachusetts to Colorado, south to Florida and Texas.

The very narrow spikelets, at most 1 mm wide, with only faintly nerved lemmas, serve to distinguish this from *E. pectinacea*, with which it is most frequently confused. The following specimens of *E. pilosa* have been determined by L. H. Harvey: Cooper Co. (*Demetrio* 35); Franklin Co. (Aug. 20, 1886, *Eggert*); Jackson Co. (July 8, 1920, *Bush* 9017); Marion Co. (*Davis* 3427); McDonald Co. (*Bush* 94); St. Louis Co. (October, 1859, *Engelmann*; July 25, 1954, *Muehlenbach* 274).

7. ***Eragrostis pectinacea*** (Michx.) Nees

Map 147

Eragrostis diffusa Buckl. [P & S, Hitchcock]

Flowers July–October.

Common throughout Missouri, where it occurs most frequently in open ground along streams and borders of ponds, in sandy, gravelly, or muddy soil, or in waste and cultivated ground.

As contrasted with *E. pilosa*, this is a native species ranging from Quebec to British Columbia south throughout much of the United States to Mexico; not recorded from some western states.

This species is frequently misidentified as *E. pilosa*, but the spikelets in *E. pectinacea* are wider (1.3–1.7 mm.) with conspicuous lateral nerves of the lemma, and the glumes are longer (the 1st glume 1 mm. long, the 2nd 1.5 mm. long, whereas in *E. pilosa* the 1st glume is 0.5 mm. long, the 2nd 1 mm. long).

Variable in habit (from erect to spreading to nearly prostrate culms, which may be few to numerous), in the complexity of branching of the panicle, and in the spikelets, which may vary in width, number of flowers to a spikelet, and number of spikelets.

Eragrostis diffusa Buckl., by some botanists considered a distinct species, by others synonymous with *E. pectinacea*, is included in this present treatment under *E. pectinacea*. On the whole, it appears to be merely a more robust-developed phase of *E. pectinacea*. The following Missouri specimens have been determined as *E. diffusa* by Dr. LeRoy H. Harvey, monographer of the genus, or are so filed at the United States National Herbarium: Barry Co. (*Palmer* 52782); Cass Co. (*Broadhead*); Franklin Co. (*Colvey*); Jackson Co. (*Bush* 31, 789, 8635); McDonald Co. (*Palmer* 4115); Pike Co. (*Davis* 9034); Pulaski Co. (*Steyermark* 19342); St. Louis Co. (Allenton, 1892, *Letterman*; St. Louis, *Eggert*).

Some of the specimens of the above group, (*Palmer* 4115 and *Bush* 8635) were at one time misidentified as *E. curtipedicellata* Buckl., a species not known from Missouri. They were later referred to *E. diffusa*.

149 *Eragrostis poaeoides*150 *Eragrostis arida*151 • *Eragrostis hirsuta* var. *hirsuta*
151 □ *Eragrostis hirsuta* var. *laevivaginata*

8. ***Eragrostis cilianensis*** (All.) Hitchcock
Stink Grass Map 148
Eragrostis megastachya (Koel.) Link [G]
Flowers June–October.

Common throughout Missouri in gardens, cultivated fields, waste ground, overgrazed dry pastures, along roads, and railroad tracks.

Native of Europe; introduced into the United States, over much of which it has spread; also introduced into Mexico and the West Indies.

This weedy annual derives its name from the somewhat disagreeable odor (to some people) of the fresh plant. The plant in either fresh or dried condition in hay is considered to be poisonous to stock, especially horses, if eaten in too large quantities. The inflorescence has a distinctive greenish-lead color.

9. ***Eragrostis poaeoides*** Beauv. Map 149
Flowers late May–October.

Infrequently collected in Missouri, where it is known in parts of southern and central Missouri north to St. Louis and Jackson counties. It is usually found in waste or open ground along railroad tracks.

Native of Europe; introduced into the United States, where it is scattered from Vermont to Wisconsin, south to Georgia, Texas, and California.

Similar in appearance to *E. cilianensis*, but smaller throughout, and the spikelets are more loosely flowered. The spikelets are purplish to lead-colored. The glandular-warty leaf-margins serve to distinguish this from *E. Frankii*, with which it is sometimes confused.

10. ***Eragrostis arida*** Hitchc. Map 150
Flowers July–October.

At present known in Missouri only from Dent,

Jackson, Polk, and Stone counties, where it is found in open ground along railroads, waste places, and gravel bars of streams. The following collections are referred to this species: Dent Co. (Rhyse, *Kellogg 1359*); Jackson Co. (Courtney, *Bush 212, 803, 892*, and June 1891, and July 22, 1935); Polk Co. (Bolivar, *Palmer 64214*).

Ranges from Arkansas and Texas to Arizona and Mexico.

All the stations in Missouri of this annual species appear to be results of introductions, rather than representing indigenous (native) plants.

11. ***Eragrostis hirsuta*** (Michx.) Nees var. ***hirsuta***
Map 151

Flowers July–October.

Mostly in southern Missouri northeast to Franklin County (4 mi. northwest of Lonedell, *Steyermark 8268*), where it is found most frequently in sand washes or alluvial deposits of small valleys and creeks, and also in sandy ground along roadsides and waste places.

Ranges from Florida to Texas, north to South Carolina and inland north to Missouri; introduced northward in Virginia, Maryland, Massachusetts, and Maine.

Spikelets are sometimes purplish in this species. Plants of this perennial species and *E. trichodes* attain the tallest of any of the Love Grasses found in Missouri, culms (stems) reaching 1.3 meters in height, while the elongated large panicles become 9 dm. long and 4.5 dm. broad.

An occasional plant occurs in which the leaf-sheaths are nearly or quite glabrous throughout except for their ciliate summit and margins. Such plants have been described as *E. hirsuta* var. *laevivaginata* Fern.,

Plate no. 24. 1. *Eragrostis pilosa*; a. Panicle, $\times \frac{3}{4}$; b. Floret, palea, $\times \frac{7}{8}$. 2. *Eragrostis pectinacea*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{8}$. 3. *Eragrostis poaeoides*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{8}$. 4. *Eragrostis intermedia*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{8}$. 5. *Eragrostis cilianensis*; a. Plant, $\times \frac{3}{8}$; b. Spikelet, $\times \frac{3}{4}$; c. Floret, $\times \frac{7}{8}$. 6. *Eragrostis arida*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{8}$. 7. *Eragrostis hirsuta*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{8}$.

PLATE NO. 24

152 *Eragrostis intermedia*153 *Eragrostis trichodes* (Sand Love Grass)154 • *Eragrostis spectabilis* var. *spectabilis* (Purple Love Grass)154 □ *Eragrostis spectabilis* var. *sparsihirsuta*

the range of which is from Florida to Maryland. A recent collection of *Palmer 67106* from Lawrence Co. (rocky open ground, border of woods, $\frac{1}{2}$ mi. south of Aurora, Oct. 12, 1957) shows most of the leaf-sheaths nearly glabrous except for the summits and margins, but the upper part of some of the leaf-sheaths have hairs on some of the surface, more characteristic of var. *hirsuta*. Such a specimen appears to be somewhat intermediate between var. *hirsuta* and var. *laevivaginata*.

12. ***Eragrostis intermedia*** Hitchc. Map 152
Flowers June–October.

Rare in parts of southern and central Missouri, where known from Texas, Christian, Jackson, Johnson, Jasper, and Newton counties. It is known from rocky prairies, thin soil in chert glades, sandy or dry open ground, meadows, and waste places.

Ranges from Missouri and Kansas, south to Louisiana, Texas, Mexico, Arizona, and California; also in Georgia.

Representative collections of this species are: Jasper Co. (*Bush 9052*); Johnson Co. (*Palmer 63114*); Newton Co. (*Palmer 52452*).

Some Missouri specimens of *E. intermedia* have been misidentified as *E. lugens* Nees, a species of Mexico, Central and South America which reaches the southern borders of the United States, but has not been found in Missouri.

13. ***Eragrostis trichodes*** (Nutt.) Wood
Sand Love Grass Map 153
Flowers July–October.

Of scattered occurrence in southern and central Missouri north to St. Louis, Carroll, and Jackson counties, where often found in sandy soils along

streams, sand washes of alluvium in valleys, or along railroads.

The following collections are representative: Jackson Co. (Courtney, *Bush 582*); St. Louis Co. (Carson Station, vicinity of St. Louis, *Eggert*; St. Louis, *Muehlenbach 1040*).

Ranges from Ohio to Nebraska, south to Louisiana and Texas.

The inflorescence of this species has a distinctly purplish color. This species is sometimes confused with the other perennial species, such as *E. hirsuta*, *E. spectabilis*, and *E. intermedia*, but is readily distinguished from them by the relatively larger first glume and lower lemma.

This grass attains a height of 1.5 meters, therefore, it is the tallest of the Love Grasses in Missouri. In the central Great Plains states, where known as 'ice-cream grass,' it is considered a very desirable and palatable forage grass for beef cattle.

14. ***Eragrostis spectabilis*** (Pursh) Steud.
Purple Love Grass Map 154
Flowers July–October.

Missouri material may be separated into the two following varieties:

Leaf-sheaths wholly glabrous (without hairs) or nearly so. . . 14a. *E. SPECTABILIS* var. *SPECTABILIS*
Leaf-sheaths, at least the lowest ones, mostly hairy. . . 14b. *E. SPECTABILIS* var. *SPARSIHIRSUTA*

14a. ***Eragrostis spectabilis* var. *spectabilis***
Occurs throughout Missouri, where it abounds along roadsides, fence-rows, sandy, rocky, or open ground, and along railroads. It is the commoner variation in the state.

155 *Eragrostis curvula* (Weeping Love Grass)156 *Diplachne fascicularis* (Salt Meadow Grass)157 *Diplachne Halei*

- b. Culms (stems) mainly erect or ascending; spikelets densely crowded, mostly conspicuously overlapping; lemmas mostly 3–4 mm. long; 2nd glume 2–3.5 mm. long 1. *D. FASCICULARIS*
- b. Culms (stems) mainly widely spreading to nearly prostrate (lying flat on ground); spikelets distant or at most slightly overlapping; lemmas 5–8 mm. long; 2nd glume 4.5–7 mm. long. 3. *D. ACUMINATA*

1. ***Diplachne fascicularis* (Lam.) Beauv.**

Map 156

Leptochloa fascicularis (Lam.) Gray [Hitchcock]*Leptochloa fascicularis* var. *fascicularis* [BB]

Flowers July–October.

Inhabits soils bordering saline and brackish springs, alluvial soils of the Missouri River and other streams, depressions in rocky glades, margins of natural ponds of central Missouri, and along railroads. Mostly in central and western Missouri, and locally eastward.

Ranges from Ohio, Minnesota, South Dakota, and Washington, south to Florida and California, the West Indies, and South America.

2. ***Diplachne Halei* Nash**

Map 157

Leptochloa panicoides (Presl) Hitchc. [BB, Hitchcock]

Flowers August–October.

Known only from New Madrid County, southeastern Missouri (from open sandy banks of the Mississippi River, October 3, 1955, *Palmer 61658*).

Ranges from Florida to Texas, inland in Indiana and Missouri, and south to Mexico, Guatemala, and Brazil.

3. ***Diplachne acuminata* Nash**

Map 158

Leptochloa fascicularis var. *acuminata* (Nash) Gl. [BB]*Leptochloa fascicularis* in part [Hitchcock]

Flowers July–September.

Occurs in wet soils in the vicinity of saline and brackish springs and occasionally in wet open ground along the Missouri River, mostly in central and northwestern Missouri.

Ranges in saline soils from Missouri, Nebraska, and North Dakota south to Louisiana and Texas.

By some botanists this is treated as synonymous with *D. fascicularis* or as a variety of it. It is here considered a separate species because of its larger lemmas and 2nd glume, more distantly spaced spikelets, and the characteristic spreading to prostrate culms.

Individuals of this species abound in the light gray brackish soils of various brackish-water springs in Saline, Randolph, Howard, and Cooper counties, associated with other unusual species, such as *Eleocharis parvula*, *Typha angustifolia*, and, occasionally, *Distichlis spicata* and *Scirpus paludosus*.

9. ***Diarrhena* Beauv.*****Diarrhena americana* Beauv.**

Map 159

Flowers June–September.

Occurs nearly throughout Missouri, where it is apparently absent only from the southeastern counties of the state. An inhabitant of woodland, it usually occurs in rich wooded alluvial soils along rivers, at the base of limestone bluffs, and, occasionally, on moist calcareous ledges and rich upland woods and ravines.

Ranges from West Virginia, Ohio, Michigan, and South Dakota, south to Georgia, Arkansas, Oklahoma, and Texas.

The species has been divided by Gleason into two varieties, separated as follows:

Leaf-sheaths mostly pubescent; callus hairy; first glume 2.2–4 mm. long; second glume 4–5.4 mm. long; lemmas ovate, 7–10 mm. long, acuminate.

a. *D. AMERICANA* var. *AMERICANA*

158 *Diplachne acuminata*159 □ *Diarrhena americana* var. *americana*
159 ● *Diarrhena americana* var. *obovata*160 *Distichlis spicata* (Seashore Salt Grass)

Leaf-sheaths glabrous or nearly so; callus glabrous; first glume 1.9–2.8 mm. long; second glume 2.4–4.3 mm. long; lemmas 5.2–6.8 mm. long, obovate, abruptly rounded into the short cusp . . .

b. *D. AMERICANA* VAR. *OBOVATA*

The species has recently been studied by Dennis Anderson, who recognizes the two varieties as meriting good varietal status, and I agree with the results of his studies.

Both variations occur in Missouri, the var. *obovata* Gleason found throughout the state and var. *americana*

known only in southwestern Missouri from Christian (*Steyermark 23037*) and Stone (*Steyermark 8197*) counties.

The three or four long slender leaves, nearly the length of the plant, ascend and eventually arch near the tip. By means of their creeping rootstocks the plants form dense colonies. Because of the dark green shining foliage, which remains green well into the winter, the plants are very striking and ornamental and should be more commonly used as a ground cover in shady wild gardens and for covering shady slopes.

10. *Distichlis* Raf. Salt Grass

Plants of this genus are dioecious (staminate and pistillate flowers on separate plants).

Growing around salt springs; margins of leaves mainly smooth, the tips rather blunt; spikelets mostly 5–12 mm. long; inflorescence condensed, the spikelets closely overlapping and hiding the pedicels (stalks of spikelets) and other spikelets; 1st glume 2–3.5 mm. long; lemmas 3.3–4.5 mm. long . . . 1. *D. SPICATA*

Growing along railroads and in waste ground; margins of leaves mainly minutely toothed, the tips sharply pointed; spikelets mostly 10–25 mm. long; inflorescence more open, plainly exposing the pedicels and individual spikelets; 1st glume 3.2–8 mm. long; lemmas 4.4–7.8 mm. long . . . 2. *D. STRICTA*

1. *Distichlis spicata* (L.) Greene

Seashore Salt Grass

Map 160

Flowers September–October.

Known only from a salt lick in Saline County (valley of Heath's Creek, east of Elk Lick Springs, sect. 17, 3 mi. southwest of Ridge Prairie, Oct. 6, 1938, *Steyermark 21581*).

Ranges in saline soils along the coasts from Nova Scotia to Florida and Texas, British Columbia to California, Mexico, British Honduras, Cuba, and western coast of South America; inland in Missouri.

This is undoubtedly the most remarkable native grass in Missouri, representing, as it does, the only interior station for the species in the United States (*Steyermark, Rhodora 42: 22–24. 1940*). At the time it was discovered in 1938, it dominated several acres of a valley containing salt springs and salt licks,

presenting the appearance of some salt marsh estuarier found along the coasts. It was associated with other species which inhabit saline soils, such as *Eleocharis parvula*, *Scirpus paludosus*, *Zannichellia palustris* var. *major*, and *Typha angustifolia*. The area probably represents an isolated relic habitat of a formerly prehistoric, more widespread saline region.

2. *Distichlis stricta* (Torr.) Rydb.

Inland Salt Grass

Map 161

Flowers June–July.

Known only from Buchanan, Jackson, and St. Louis (*Muehlenbach 976*) counties, where it is found along railroads and in waste ground.

Ranges from Minnesota and Manitoba to British Columbia, south to Missouri, Oklahoma, Texas, California, and Mexico.

161 *Distichlis stricta* (Inland Salt Grass)162 *Uniola latifolia* (Spike Grass)163 *Uniola laxa*11. *Uniola* L. Spike Grass

In this genus the lowermost florets of the spikelets are empty, and do not contain stamens or pistils.

Leaf-blades mainly 8–25 mm. wide; mature inflorescence with drooping branches and spikelets; spikelets 6–20-flowered, 15–40 mm. long, 10–20 mm. broad; common species 1. *U. LATIFOLIA*

Leaf-blades mainly 3–6 mm. wide; inflorescence with erect branches and spikelets; spikelets 1–5 (–7)-flowered, 3–9 mm. long, 2.5–5 mm. broad; known only from Ripley County. 2. *U. LAXA*

1. *Uniola latifolia* Michx.

Broadleaf Uniola, Spike Grass

Map 162

Flowers June–October.

Throughout southern and central Missouri, and in the northeastern half west to Livingston and Grundy counties. Absent from the northwestern section and the lowlands of southeastern Missouri. Frequents alluvial soils and rich woods or rocky slopes along streams, moist bluffs, especially in limestone areas.

Ranges from New Jersey, Pennsylvania, Ohio, Illinois, Missouri, and Kansas, south to Florida and Texas.

The large drooping inflorescences with their broad flattened pale spikelets provide material for decorative

winter bouquets and backgrounds for flower arrangements.

2. *Uniola laxa* (L.) BSP.

Map 163

Flowers July–October.

Known only from wet woods of a swale bordered by knolls in Ripley County, southeastern Missouri (T22N, R4E, $\frac{1}{4}$ southwest sect. 35, $4\frac{3}{4}$ mi. south of Naylor, October 19, 1948, *Steyermark 66921*).

Ranges from Florida to Texas, north to New York, Pennsylvania, Kentucky, Missouri, and Oklahoma.

On account of its dark glossy green foliage, this species was confused by Bush (*Bush 6123* from Monteer, Shannon Co., Aug. 6, 1910, in N. Y. Bot. Gard. Herb.) with *Diarrhena americana*. This collection was labeled by him *Uniola laxa*.

12. *Dactylis* L. Orchard Grass***Dactylis glomerata* L.** Orchard Grass Map 164

Flowers May–August.

Found throughout Missouri in fields, waste ground, roadsides, fence rows, and wooded thickets bordering pastures.

Native to Europe; introduced into North America, where it is widely spread from Newfoundland to Alaska south to Florida and California.

Most of the Missouri material falls into *D. glomerata* var. *glomerata* with long-ciliate keels of the glumes and lemmas, which are glabrous on the back. A collection

(fields, Grundy Co., June 27, 1937, *D. R. Crookshanks 255*) in the University of Missouri Herb. has short scabrous keels characteristic of *D. glomerata* var. *detonsa* Fries, but the short appressed hairs on the lemma indicate interbreeding with *D. glomerata* var. *ciliata* Pterm.

Spikelets vary from pale green to suffused with wine-purple. There is a striking resemblance in the field between this grass and the early flowering stage of *Phalaris arundinacea*. The broader stiffer leaves and glabrous glumes and lemmas of the latter dis-

164 • *Dactylis glomerata* var. *glomerata*
 164 □ *Dactylis glomerata* var. *detonsa*

165 *Arundo Donax* (Giant Reed)

166 *Phragmites communis* var. *Berlandieri* (Reed)

tinguish it from the relatively narrower leaves and more or less hairy glumes and lemmas of *Phragmites*, in addition to the technical differences of the number of florets in the spikelet.

This grass was formerly more commonly sown for both pasture and hay, combining drouth resistance

with early pasturing properties. It is considered one of the most important hay fever-causing grasses in the United States; it sheds its pollen mainly during May and June about the same time when Blue Grass (*Poa pratensis*) is actively pollinating the air.

13. *Arundo* L. Giant Reed

***Arundo Donax* L. Giant Reed**

Map 165

Flowers September–November.

Often cultivated as an ornamental grass, but rarely escaping and persistent away from cultivation. It has escaped and persisted in Dunklin Co. (Nov. 24, 1892, *Bush*), Boone Co., and Jasper Co. (waste ground in the old mines, $\frac{1}{2}$ mi. southeast of Webb City, October 8, 1953, *Palmer 57005*). At these localities it has also flowered.

Native to the Mediterranean region; introduced and escaped north in the United States to Virginia and Missouri.

In Italy and Argentina the grass is a source of pulp for paper. In Europe reeds of clarinets and organ pipes have been obtained from the culms (stems), and in some parts of the southwestern United States the culms are used as framework in the construction of adobe huts, and for screens and mats.

14. *Phragmites* Trin. Reed

Phragmites communis* Trin. var. *Berlandieri

(Fourn.) Fern. Reed

Map 166

Phragmites communis Trin. [BB, Hitchcock]

Flowers July–September.

Alluvial ground in valleys, along the larger rivers, and in low ground and swales bordering ponds and ditches in northern and central Missouri south to Callaway, Moniteau, and Bates counties.

Ranges from Quebec and Nova Scotia to British Columbia, south to Maryland, Ohio, Indiana, Illinois, Missouri, Louisiana, Texas, California, Mexico,

British Honduras, and Guatemala.

The broad leaves are suggestive of corn.

In Italy and Rumania the stems are used as a source of pulp for papermaking. As with *Arundo Donax*, the stems are used in the southwestern United States as a framework in the construction of adobe houses. The stems have also been used for thatching, nets, screens, mats, and as shafts for arrows.

Various parts of the plant may be eaten as follows: when young and beginning to unfold, the leaves can be cooked as greens. In early spring the young shoots

167 *Melica nitens* (Melic Grass)168 • *Tridens flavus* f. *flavus*
□ *Tridens flavus* f. *cupreus*169 *Tridens oklahomensis*

can be boiled and eaten as a substitute for asparagus. At a time previous to flower formation, the stems, rich in carbohydrates and with a fleshy consistency, are collected, dried, and after being beaten into a flour, the finer part is sifted out, moistened, and roasted,

and then eaten in the manner of a taffy or marshmallow. The stout rhizomes can be boiled and eaten like potatoes. The seed is nutritious. The whole grain can be cooked into a wholesome gruel.

15. *Melica* L. Melic Grass

Melica nitens Nutt. Melic Grass

Map 167

Melica Porteri [of P & S], not Scribn.

Melica mutica [of P & S], not Walt.

Flowers April–July.

Common in limestone areas in open rocky woods, on bluffs, and open rocky limestone glades, and prairies. Throughout Missouri, except absent in the lowlands of southeastern Missouri. Ranges from Pennsylvania to Minnesota, south to Virginia, Kentucky, and Texas. All material in Missouri, previously identified as *M. mutica*, is here included, following Dr. Boyle's studies of the genus, under *M. nitens*.

Excluded species

Melica Porteri Scribn.

The basis for the original assignment of this species

to the Missouri flora is a specimen from Jackson County (common on bluffs, at Swope Park, May 17, 1896, *Bush 856*) deposited in the United States National Herbarium. Originally labeled as *M. mutica*, it was later identified by Scribner as *M. parviflora* (Porter) Scribn., which name is synonymous with *M. Porteri*. The specimen was then taken up under the latter name and included from Missouri in Hitchcock's first edition (p. 200) of *Manual of Grasses*. It was later found to be misidentified and correctly determined as *M. nitens*. *Gray's Manual*, eighth edition and Gleason's *New Illustrated Flora*, however, have continued the error in identification, taken from Hitchcock's *Manual*. The species should be eliminated from the flora of the state.

16. *Tridens* Roem. & Schult

(*Triodia* of some Am. auth., not R. Br. [G, BB, Hitchcock, ed. 1])

The decision to use the generic name *Tridens* instead of *Triodia* follows the reasons given in the second edition of Hitchcock's *Manual* (p. 997), supported also by the work of Hubbard (1937), Burbridge (1946), and Shinnars (1954). In the main, *Tridens*, confined to the western hemisphere, has the lemmas 3-nerved only, with the lateral nerves of the lemma marginal or nearly so, whereas *Triodia*, indigenous to Australia, consists of tussock grasses with rigidly pungent-pointed leaves, the spikelets having lemmas mostly in 3 groups of 2 or 3 nerves each, with the lateral nerves of the lemma not marginal.

PLATE NO. 27

- a. Inflorescence loose, open, the branches spreading widely b
- b. Spikelets straw-colored or greenish-yellow in all stages of development 1a. *T. FLAVUS* f. *FLAVUS*
- b. Spikelets dull or deep purple or rose-purple c
- c. Swollen base (pulvinus) of each main branch of inflorescence short-hairy on upper side only; lateral spikelets appressed along or paralleling the branches, on short stalks up to 3 mm. long at most; branches of inflorescence spreading-ascending 1b. *T. FLAVUS* f. *CUPREUS*
- c. Swollen base (pulvinus) of each main branch of inflorescence surrounded by long hairs on all sides; spikelets conspicuously divergent (spreading out from the attachment), on stalks 3–20 mm. long; branches of inflorescence widely spreading and remote, presenting an open skeleton-like inflorescence 3. *T. CHAPMANI*
- a. Inflorescence contracted, slender, narrow, the branches ascending close to main axis d
- d. Sticky (viscid) hairs near summit of culm (stem) and on branches of inflorescence; inflorescence dark or dull purple 2. *T. OKLAHOMENSIS*
- d. No sticky (viscid) hairs either near summit of culm or on branches of inflorescence; inflorescence brownish, straw-color, gray-green, or tinged with rose-purple, but not dark or dull purple e
- e. Culms and leaf-sheaths smooth; spikelets 4–6 mm. long; glumes glabrous with glandular-viscid (sticky) keel; lemmas mucronate (with a tiny projection at tip) 4. *T. STRICTUS*
- e. Culms and leaf-sheaths rough or scabrous (fine short stiff hairs); spikelets 7–12 mm. long; keel (narrow back edge) of glumes scabrous; lemmas obtuse (blunt) 5. *T. ELONGATUS*

1. ***Tridens flavus* (L.) Hitchc.**

Purpletop, Tall Redtop Map 168
Triodia flava (L.) Smyth [G, BB, Hitchcock, ed. 1]
 Flowers July–August.

Fields, pastures, sandy open ground, rocky glades, open, often cut-over woodland, waste ground, and along roadsides. The common purple form, *T. flavus* f. *cupreus* (Jacq.) Fosb., is known from every county in Missouri. The rare form, *T. flavus* f. *flavus*, with straw-colored or greenish-yellow spikelets is known from Phelps (openings along road in valley of Kaintuck Hollow, T36N, R9W, sect. 10, 4½–4¾ mi. south southwest of Newburg, September 11, 1956, *Steyermark 82568*) and Lawrence (dry sandy open ground along small ravine, 1½ mi. northeast of Nickelville, October 20, 1953, *Palmer 57099*) counties.

Occasionally plants are found which show some intergradation in color, with a slight pale purplish tinge on spikelets mostly pale greenish or straw-color. An example of this is *Palmer 65957* from Newton County.

Ranges from New Hampshire to Minnesota and Nebraska, south to Florida and Texas.

Although this grass is one of the most abundant in Missouri, it is practically absent from the northern third of nearby Illinois and Indiana.

As the seed matures, the branches of the inflorescence and upper portion of the culm secrete a sticky substance which darkens as the plant becomes exposed to dust and air particles. The hands of unknowing persons receive a greasy blackish streak upon handling the mature inflorescence.

During the early stages of growth, livestock find this grass quite palatable.

2. ***Tridens oklahomensis* (Feath.) Feath.**

Map 169

Triodia oklahomensis Feath. Rh. 40: 243. 1938.
 Flowers September–October.

Known only from Boone County (moist soil, T48N, R13W, sect. 3, September, 1955, *Kucera*), where associated with *T. flavus* and *T. strictus*.

Known only from Oklahoma, where originally discovered by Mr. A. E. Wade, and from Missouri.

The spikelets, which are 6–8 mm. long, 4 mm. wide, and 7–9-flowered, are deep purple as in *T. flavus* f. *cupreus*, and resemblances to the Purpletop are also found in the viscid-sticky inflorescence, in size of plant, and habitat. The branches of the inflorescence of *T. oklahomensis* have many more flowers crowded along their branches than in *T. flavus*. Dr. Kucera (Rh. 59: 72. 1957) suggests that *T. oklahomensis* may be of hybrid origin, as it has been found in various stations where *T. flavus* and *T. strictus* were growing with it, and shows characters partaking of both these species.

3. ***Tridens Chapmani* (Small) Chase** Map 170

Triodia Chapmani (Small) Bush [G]
Triodia flava var. *Chapmani* (Small) Fern. & Grisc.
Tridens flavus var. *Chapmanii* (Small) Shinnars
 Flowers August–September.

Known only from Shannon County (rocky woods, September 10, 1908, *Bush 5126*).

Ranges from Florida to Texas, north to New Jersey, Virginia, Tennessee, and southeastern Missouri.

Intergradation between this and *T. flavus* has, thus far, not been noted. Dr. Fernald concluded it was a distinct species after several years of field observations.

Until additional Missouri collections are made and become available for study, *T. Chapmani* is, likewise, being retained as a species separate from *T. flavus*.

- 4. **Tridens strictus** (Nutt.) Nash Map 171
Flowers July–October.
Prairies, sandy open ground, and moist or dry open ground along ditches and roadsides in southern Missouri locally north to Boone County.
Ranges from Alabama to Texas, north to Tennessee, Missouri, and Kansas.

- 5. **Tridens elongatus** (Buckl.) Nash Map 172
Triodia elongata (Buckl.) Scribn. [G, BB, Hitchcock, ed. 1]
Tridens muticus (Torr.) Nash, var. *elongatus* (Buckley) Shinn
Flowers June–October.
Limestone glades and rocky ledges of limestone bluffs in southwestern Missouri north to Benton and Henry counties.
Ranges from Missouri to Colorado, south to Arkansas, Texas, and Arizona.

17. **Triplasis** Beauv. Sand Grass

- Triplasis purpurea** (Walt.) Chapm.
Sand Grass Map 173
Flowers August–November.
Sand dunes and flats along the Missouri and Mississippi rivers, and locally in sandy soil in Ozark and Dunklin counties.
Ranges along the coast from Maine to Florida and Texas, inland on the shores of the Great Lakes from New York and Ontario to Minnesota and Colorado,

south into Illinois, Missouri, Arkansas, and Texas.
The occurrence of this grass is practically always with a habitat of pure or nearly pure sand. Along the sand dunes of the Mississippi and Missouri rivers it is commonly associated with other sand-loving species, such as *Sporobolus cryptandrus*.
Among grasses this species is unusual in having an acid taste.

Tribe III. **HORDEAE**

Grasses of this tribe have usually sessile (stalkless) or nearly sessile spikelets arranged in rows on opposite sides of the central axis, the spikelets are usually 2- or more-flowered, or sometimes 1-flowered, and the rachilla is articulated above the glumes.

18. **Agropyron** Gaertn. Wheat Grass

- a. No underground elongated creeping rootstocks present; anthers mainly 1–2.5 mm. long; mature spikelets breaking apart easily, the individual florets of the spikelets separating from one another; glumes persisting after lemmas fall 3. **A. TRACHYCAULUM**
- a. Underground elongated creeping rootstocks present; anthers mainly 3–7 mm. long (rarely shorter); mature spikelets falling as a whole, not breaking apart into the separate florets; glumes not persisting after lemmas fall b
- b. Leaves silvery blue-green, stiff, deeply grooved on upper side with inrolled margins; rootstocks

173 *Triplasis purpurea* (Sand Grass)174 • *Agropyron repens* var. *subulatum* f. *subulatum*
(Quack Grass)174 □ *Agropyron repens* var. *subulatum* f. *Vaillantianum*

- dull brown or yellowish-brown; upper nodes (joints) of stems with the swollen portion shorter than broad (thick); spikelets 6-16-flowered, 15-28 mm. (excluding awns) long . . . 2. *A. SMITHII*
 b. Leaves deep green or bluish-green, flexible and rather soft, flat and not deeply grooved; rootstocks white or yellowish-white, sometimes with lavender sheaths; upper nodes (joints) of stems with the swollen portion longer than broad (thick); spikelets mostly 3-6-flowered, mostly 10-16 mm. (excluding awns) long I. *A. REPENS*

1. ***Agropyron repens* (L.) Beauv.** Map 174
Quack Grass

Flowers late May-September.

Fields, gardens, fence rows, thickets, along roadsides, and waste ground.

Typical *A. repens* var. *repens* has not been found, thus far, in Missouri. Missouri material may be divided into the two following segregates:

No awns protruding from tip of lemma

1a. *A. REPENS* var. *SUBULATUM* f. *SUBULATUM*
Awns protruding from tip of lemma . 1b. *A. REPENS*
var. *SUBULATUM* f. *VAILLANTIANUM*

1a. ***A. repens* var. *subulatum* (Schreb.) Reichenb.**
f. ***subulatum*** Map 174

This is the more common variation in Missouri, and is more or less scattered over the entire state. Only a comparatively few herbarium records exist, as may be noted on the accompanying map, but undoubtedly the plants occur in nearly every county of the state.

1b. ***A. repens* var. *subulatum* f. *Vaillantianum***
(Wulf. & Schreb.) Fern. Map 174

This variation is occasionally found in the state. A representative specimen is *Steyermark 7888* (near Pacific, Franklin County, June 8, 1930) in the Mo. Bot. Gard. Herb.

Agropyron repens var. *repens* and its other varieties and forms were chiefly introduced in the early 1800's

from Europe, and have since spread over most of North America. Along the north Atlantic coast there are apparently indigenous wild varieties.

During June and July when *A. repens* var. *repens* and its other varieties and forms are at the height of pollen production, they are considered to be a contributing factor in causing hay fever, but, because of the small amount of pollen produced, are of only secondary importance.

The creeping underground rootstocks have been dried and ground into a flour for use in making bread (Withering, 1830). This is a very bad weed. Once it gets established in gardens, especially vegetable gardens or strawberry beds, it is practically impossible to eradicate. Chemicals for getting rid of the grass are being developed, but as yet no positive selective chemical killer has been effective, and the only practical method thus far known is spading up each plant and picking out the roots and then burning them. Turning a couple of geese loose in plots of ground where Quack Grass is rampant is said to constitute an effective measure for eradicating it, but unfortunately the geese eat other desirable plants. The tough rootstocks may travel from 2 to 8 inches below the surface of the ground. The root system produces a heavy and packed soil, and, for this purpose, sometimes is used for stabilizing embankments and waterways. The grass is palatable to livestock and is used for pasture and hay production.

PLATE NO. 28

2. **Agropyron Smithii** Rydb.

Western Wheat Grass

Map 175

Flowers May–August.

Rather common along railroad tracks in northern and central Missouri, and also in fields, prairies, along roadsides, and waste ground. Not yet recorded from southeastern Missouri.

Ranges from New York, Ontario, and Alberta to Washington, south to Tennessee, Arkansas, Texas, Arizona, and California; spreading eastward to Quebec and New Hampshire.

Missouri material previously misidentified as *A. spicatum* (Pursh) Scribn. & Smith, a western species, and as *A. pseudorepens* Scribn. & Smith (synonymous with *A. trachycaulum* var. *majus* [Vasey] Fern.), has been referred to *A. Smithii*.

This species is easily recognized by the silvery blue color of the leaves and culms, and by the stiff rigid leaves with inrolled margins (involute). The name 'Bluestem' is sometimes applied to this species.

The grass, during its period of flowering (mostly June and July) is believed to be of some importance in causing hay fever. It is considered to be nutritious, and is commonly eaten by livestock, principally in the Great Plains and Pacific Northwest states where it is native. Its hay ranks high in protein value.

3. **Agropyron trachycaulum** (Link) Steud.

Bearded Wheat Grass, Awned Wheat Grass

Map 176

Flowers June–August.

Missouri material falls into two varieties:

No awns present or awns at most only half as long as the body (awnless part) of the lemma . . .

3a. *A. TRACHYCAULUM* var. *TRACHYCAULUM*

Awns present and nearly as long as or longer than

the body (awnless part) of the lemma . . .

3b. *A. TRACHYCAULUM* var. *GLAUCUM*3a. **Agropyron trachycaulum** (Link) Steud.var. *trachycaulum*

Map 176

Agropyron trachycaulum (typical) [G]*Agropyron pauciflorum* (Schwein.) Hitchc. [Hitchcock ed. 1]*Agropyron tenerum* Vasey

Fields, waste ground, and cemeteries. Known thus far from a few eastern (Marion, Ralls, Pike, St. Louis) and western (Jackson, Jasper) counties.

Var. *trachycaulum* ranges from Quebec and Ontario to Alaska, south to Illinois, Iowa, Missouri, Kansas, New Mexico, and California.

3b. **Agropyron trachycaulum** var. *glaucum*

(Pease & Moore) Malte

Map 176

Agropyron caninum of Am. auth., not Beauv.

Known only from Newton County (open ground in grassy and weedy field, 2 mi. southeast of Joplin, July 26, 1957, *Palmer 66179*).

Ranges from Newfoundland to British Columbia, south to Maryland, Pennsylvania, Michigan, Wisconsin, Missouri, Nebraska, Colorado, Nevada, and California.

Missouri material has been confused with var. *unilaterale*.

*Excluded species and varieties***Agropyron trachycaulum** var. *unilaterale*

(Cassidy) Malte

Missouri is cited in the range of this variety in Gleason's *Illustrated Flora* (p. 140), but the Missouri specimens are referred in this work to var. *trachycaulum*. Some material so identified has been placed in var. *glaucum*.

19. **Triticum** L. Wheat**Triticum aestivum** L. Wheat

Map 177

Flowers early May–July.

This cultivated annual has been introduced from Eurasia.

Frequently seed is scattered along roads, railroad tracks, and in waste ground, where it germinates and grows, but does not actually persist or perpetuate itself as part of the introduced flora in the manner

of most other introduced species.

Because of the tendency for wheat to be self-pollinated, it can be considered only a minor cause of hay fever.

Straw from this species is used for pulp in paper making in some parts of the United States, South America, Europe, North Africa, and Asia Minor.

PLATE NO. 29

Aegilops cylindrica Host Goat Grass Map 178
Flowers May–August.

Usually found along railroad tracks, or in dry open ground along roads and waste places. Until 1935 recorded from Jackson County only. Since then it has become increasingly more common, and at pre-

sent is known from eleven counties in the state.

Native of Europe; introduced into the United States, where it has extended its range from Colorado and New Mexico east to Oklahoma, Missouri, Indiana, and locally to New York.

21. *Secale* L. Rye

Secale cereale L. Rye Map 179
Flowers April–June.

Commonly cultivated annual and germinating along roadsides, railroad tracks, alluvial banks, and waste ground, but never persisting. Scattered over the state.

Originated in Eurasia.

The abundant pollen shed from Rye during its flowering season, extending mainly from May to June, is considered to be the cause of some hay fever, more especially in Europe.

The dried straw of the stems is used principally in central Europe as pulp in the making of paper.

22. *Elymus* L. Wild Rye

The leaf-blades have an auricle (outgrowth) at base. The spikelets are 2–6- (rarely 1-) flowered, and usually occur in 2's at each joint of the rachis, or rarely in 3's or solitary at the joint.

- a. No awns or very short inconspicuous awns at most 3 mm. long present on the spikelets . . . 6e. *E. VIRGINICUS* var. *SUBMUTICUS*
- a. Conspicuous awns 5–40 mm. long present on the spikelets . . . b
- b. Awns at maturity curved, bending, or spreading outward; palea 8.5–11 mm. long . . . c
- c. Glumes bristle-like their entire length, not broadened above the base, not noticeably nerved, 2–15 mm. long (including the awn); spikelets 2–3-flowered . . . 3. *E. INTERRUPTUS*
- c. Glumes bristle-like in upper half, but broadened above base in lower half, where 3–5-nerved, 15–35 mm. long (including the awn); spikelets 2–5-flowered. . . 4. *E. CANADENSIS*
- b. Awns at maturity straight or nearly straight, at least not curved or spreading outward; palea mainly 5–8 mm. long. . . d
- d. Glumes 0.8–2.5 mm. wide, flat, at least above the base, not bristle-like in the lower half; spikes mainly erect, stiff . . . e
- e. Glumes not thickened at base, rather thin, straight; internodes of rachis 8–10 mm. long; limestone bluffs of southwestern Missouri . . . 1. *E. GLAUCUS*

1. ***Elymus glaucus* Buckley**

Blue Wild Rye

Map 180

Elymus Mackenzii Bush, Am. Midl. Nat. 10: 53. 1926 (holotype, *Bush* 77 from Eagle Rock, Barry County).

Flowers late May–August.

Usually found on rocky limestone ledges of bluffs along White River and tributaries and other streams of southwest Missouri, east to Ozark County and north to Barton County.

Ranges from western New York and Ontario to Michigan, south to Missouri and Arkansas; and Alaska to California and New Mexico.

Bush originally labeled his specimens of this species as *E. Macounii* Vasey, which species does not occur in Missouri.

This is a distinctive species of the White River and adjacent southwestern Missouri area. It is mostly glabrous with 3–6-flowered spikelets, 3–5-nerved short-awned glumes which are shorter than the nearly glabrous lemma. The elongated internodes of the rachis, up to 8–10 mm. long, are much longer than are found in any other Missouri species of *Elymus*. However, internodes only 5 mm. long are commonly encountered.

2. ***Elymus villosus* Muhl.**

Map 181

Elymus canadensis var. *villosus* (Muhl.) Shinnars

Flowers June–September.

Rich or rocky woods, on slopes, ridges, alluvial wooded banks of streams, thickets, sometimes in prairies, and along roadsides.

Ranges from Quebec to North Dakota, south to North Carolina, Alabama, Arkansas, Oklahoma, Texas, and New Mexico.

Missouri material may be separated as follows:

- Glumes and lemmas villous (bearing long soft hairs) 2a. *E. VILLOSUS* f. *VILLOSUS*
- Glumes and lemmas glabrous or merely scabrous (very short rough hairs) 2b. *E. VILLOSUS* f. *ARKANSANUS*

2a. ***Elymus villosus* f. *villosus***

Map 181

Common throughout Missouri.

2b. ***Elymus villosus* f. *arkansanus***

Map 181

(Scribn. & Ball) Fern.

Mostly in southern Missouri, locally northward to Miller, St. Charles, Pike, and Gentry counties.

The leaf-sheaths vary from pubescent to glabrous. The spikes are usually declined or nodding.

3. ***Elymus interruptus* Buckl.**

Map 182

Flowers June–August.

Prairies and rocky wooded slopes. Known only from three counties in western Missouri, in Gentry County (natural prairie along road Z, 2.8 mi. west of Berlin, northeast $\frac{1}{4}$ sect. 33, July 30, 1954, *Steyermark*

Plate no. 31. 1. *Hordeum pusillum*, $\times \frac{3}{4}$. 2. *Hordeum jubatum*, $\times \frac{3}{4}$. 3. *Hystrix patula*; a. Plant, $\times \frac{3}{8}$; b. Spikelet, $\times 2\frac{1}{4}$; c. Floret, $\times 2\frac{1}{4}$. 4. *Sphenopholis intermedia*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times 7\frac{1}{2}$; c. Glumes, $\times 7\frac{1}{2}$. 5. *Sphenopholis nitida*; a. Panicle, $\times \frac{3}{4}$; b. Florets, $\times 7\frac{1}{2}$; c. Glumes, $\times 7\frac{1}{2}$.

PLATE NO. 31

182 *Elymus interruptus*183 • *Elymus canadensis* f. *canadensis* (Canada Wild Rye)
□ *Elymus canadensis* f. *glaucifolius*184 *Elymus riparius*

76299), Lafayette County (wooded rocky hillside along Missouri River, $1\frac{1}{2}$ mi. northeast of Dover, June 12, 1953, *Palmer 55939*), and Barry County (rocky open woods, near Viola, August 26, 1957, *Palmer 66416*).

Ranges from Wisconsin to North Dakota and Wyoming, south to Tennessee, Oklahoma, Texas, and Mexico.

This resembles a hybrid between *Elymus canadensis* and *Hystrix patula* as well as suspected of being one between *Elymus canadensis* and *E. villosus*. The spike is rather loosely flowered below and the lemmas are hirsute with spreading awns 2–4 cm. long.

4. ***Elymus canadensis* L.** Canada Wild Rye,
Nodding Wild Rye Map 183
Flowers June–October.

Prairies, rocky open woods, rocky slopes of bluffs, alluvial woods, open banks of river, and waste ground. Occurring in most parts of the state, but mostly absent, so far as available records go, from the southeastern section.

Ranges from New Brunswick to Alaska, south to North Carolina, West Virginia, Ohio, Indiana, Illinois, Missouri, Texas, New Mexico, Arizona, and California.

Two forms are recognized, both about equally common:

- Lemmas villous-hirsute (noticeably hairy).
4a. *E. CANADENSIS* f. *CANADENSIS*
Lemmas glabrous or at most scabrous.
4b. *E. CANADENSIS* f. *GLAUCIFOLIUS* (Muhl.) Fern.

Some plants are more glaucous or silvery blue-green than others. There is also considerable variation in width and pubescence of leaf-blades, and in length and pubescence of lemmas and awns.

The species is of minor importance in causing hay fever.

As the flower spikes mature, they curve or droop downward. A black fungus, ergot, sometimes infests

the flowering heads of this species and of *E. virginicus*. This grass is very palatable and is eaten by all classes of livestock. It provides good forage and hay, and is nutritious.

5. ***Elymus riparius* Wieg.** Map 184
Flowers June–September.

Along rocky wooded slopes, bluffs, and banks of streams, where frequent in the Ozark region, and extending north locally to Pike, Adair, and Linn counties.

Ranges from Maine and Quebec to Wisconsin, south to Florida, Kentucky, and Arkansas.

The long downward-curving or nodding spikes, wide glabrous leaf-blades (1–2.2 cm. wide), glabrous leaf-sheaths, internodes of rachis 3–8 mm. long, palea 7.5–8 mm. long, and bristlelike glumes only 0.4–0.8 mm. wide are distinguishing characters of this species.

6. ***Elymus virginicus* L.** Wild Rye Map 185
Flowers late May–September.

A great variety of habitats are occupied by the various varieties and forms of *E. virginicus*. The most common habitats are in low woods, valley bottoms, and alluvial wooded banks of streams, but other habitats, such as prairies, open or sandy fields, rocky exposures on bluffs, wooded limestone ledges, and rocky limestone glades, are occupied.

The combined varieties and forms of *E. virginicus*, which occur throughout Missouri, range from Newfoundland to Alberta, south to Florida and Arizona.

The following variations are found in Missouri:

- a. No conspicuous awns at tip of glumes or lemmas, the glumes and lemmas ending only in a short point or subulate tip, or prolonged into an awn at most 3 mm. long. 6d. *E. VIRGINICUS*
var. *SUBMUTICUS*
a. Definite conspicuous awns 5–40 mm. long at tip of glumes or lemmas b

- Elymus virginicus* f. *hirsutiglumis* (Scribn.) Fern. [G, P & S]
Common throughout Missouri. Often found in open sandy fields, rocky bluff exposures, prairies, open and alluvial woods.
- 6c. ***Elymus virginicus* var. *jejunus*** (Ramaley) Bush Map 185
Not recorded from northwestern Missouri, elsewhere in the state common in fields, open woods, wooded limestone ledges, prairies, glades, and waste ground.
- 6d. ***Elymus virginicus* var. *submuticus*** Hook. Map 185
The rarest of the varieties and forms of *E. virginicus* in Missouri, where scattered over the state.
- 6e. ***Elymus virginicus* var. *glaberrimus*** (Vasey) Bush f. *glaberrimus* Map 185
Elymus virginicus var. *glaberrimus* (Vasey) Bush [G, P & S]
Common throughout Missouri, where often found in open, rocky, rich, or alluvial woods, and on limestone glades.
- 6f. ***Elymus virginicus* var. *glaberrimus*** (Vasey) Bush f. *australis* (Scribn. & Ball) Fern. Map 185
Mostly occurring in the Ozark section of the state and in eastern Missouri. Apparently absent and not recorded from most of the glaciated prairie section of the northwestern half of the state. Occurs commonly in rocky open woods, glades, open sandy fields, and prairies.
- Elymus virginicus* is a very palatable and nutritious grass, and is eaten by all classes of livestock. It provides good hay and forage.

23. **Sitanion** Raf. Squirreltail**Sitanion longifolium** J. G. Smith

Squirreltail Map 186

Sitanion Hystrix of many authors [BB, G, P & S],
not (Nutt.) J. G. Smith

Flowers May–August.

Known only from Jackson County, western Missouri, where introduced (Sheffield, June 2, 1906,

Bush 3907). This specimen has been determined by F. Douglas Wilson, and is in the herbarium of the New York Botanical Garden. There is also a specimen in the Missouri Botanical Garden Herbarium.

Ranges from South Dakota to British Columbia, south to Missouri, Texas, California, and Mexico.

24. **Hystrix** Moench Bottlebrush

The leaf-blades have tiny auricles (outgrowths) at base.

Hystrix patula Moench Bottlebrush Map 187

Flowers June–August.

Commonly occurring in dry rocky or open woodland, less frequently in open or waste ground. Throughout Missouri, where apparently absent from the lowland southeastern section and a few extreme western counties.

Ranges from Maine to North Dakota, south to Georgia, Tennessee, Arkansas, and Oklahoma.

Occurs in two forms in Missouri:

Lemmas glabrous **H. PATULA** f. **PATULA**
Lemmas pubescent **H. PATULA** f. **BIGELOVIANA****Hystrix patula** Moench f. **patula** Map 187*Hystrix patula* Moench [G, P & S]

This is the common form encountered in Missouri.

Hystrix patula f. **Bigeloviana** (Fern.) Gl.

Map 187

Hystrix patula var. *Bigeloviana* (Fern.) Deam [G]Known from Atchison (*Steysmark 85716*), Holt (*Steysmark 73829*), and Jackson (*Bush*, June 22, 1890) counties of northwestern and west-central Missouri.25. **Hordeum** L. Barley

The narrow glumes, with their position in front of the 3 spikelets at each node, give the appearance of 6 involucre-like bracts or bristles on a spikelet.

The central one of the 3 spikelets of a group is sessile and perfect, while the other 2 (lateral ones) are shortly stalked and sterile or reduced in size, but in some species these are sessile and mostly perfect and as large as the central spikelet.

- a. No awns on lemma 3b. **H. VULGARE** var. **TRIFURCATUM**
a. Long slender awns on lemma *b*
b. Conspicuous auricles (loose projections or outgrowths) present at top of leaf-sheath; awns of lemma stout, flat, 1 mm. wide at the base, 0.5 mm. or less wide on most of length, much longer than the short bristle-like awns of the glumes; leaf-blades mainly 5–15 mm. wide . 3a. **H. VULGARE** var. **VULGARE**
b. No auricles at top of leaf-sheath; awns of lemma bristle-like, 0.2–0.5 mm. wide at the base, similar to and about equaling the long awns of the glumes; leaf-blades 1–6 mm. wide *c*
c. Inflorescence nodding or curving down; awns curving outward or spreading at maturity; spikelets 30–70 mm. (in a rare var. *caespitosum* 15–30 mm.) long (measured from the base to the tip of awn); all glumes bristle-like throughout 1. **H. JUBATUM**
c. Inflorescence erect; awns erect or ascending, straight at maturity; spikelets 12–20 mm. long (measured from base to tip of awn); at least some of glumes broadened above bases . . 2. **H. PUSILLUM**

1. **Hordeum jubatum** L.

Squirreltail, Foxtail Barley Map 188

Flowers May–October.

Fields, pastures, roadsides, along railroads, and waste ground. Of common occurrence over the north-

ern half of the state, but so far as records exist, the grass is scarce and in many parts absent south of the Missouri River.

Extends from Labrador to Alaska, south to Newfoundland, Virginia, Kentucky, Illinois, Missouri,

188 • *Hordeum jubatum* var. *jubatum* (Squirreltail)
188 □ *Hordeum jubatum* var. *caespitosum*

189 *Hordeum pusillum* (Little Barley)

190 • *Hordeum vulgare* var. *vulgare* (Barley)
190 □ *Hordeum vulgare* var. *trifurcatum* (Beardless Barley)

Texas, California, and Mexico. Introduced into South America, Europe, and Asia.

Missouri material falls into two varieties:

Spikelets, including awns, 30–70 mm. long . . .

1a. *H. JUBATUM* var. *JUBATUM*

Spikelets, including awns, 15–30 mm. long . . .

1b. *H. JUBATUM* var. *CAESPITOSUM*

1a. ***Hordeum jubatum* L. var. *jubatum* Map 188**

Hordeum jubatum L. [G, BB, P & S]

Common variety encountered.

1b. ***Hordeum jubatum* var. *caespitosum* (Scribn.) Hitchc. Map 188**

Known only from St. Louis County (along central switching tracks, freight yard Brennan Ave., Terminal R. R. Association, St. Louis, July 4, 1956, *Muehlenbach* 995).

Sometimes called 'Bobtail Barley.' When dry, the bristly awns easily penetrate the mouth parts and eyes of grazing sheep, cattle, and horses, being especially troublesome in the Rocky Mountain states. The young inflorescence of this species sometimes takes on a beautiful rose-purple color with a glistening effect in the sunlight.

2. ***Hordeum pusillum* Nutt. Little Barley Map 189**

Flowers late April–late June.

Occurs in waste and cultivated ground, along roadsides, and railroad tracks throughout Missouri.

Ranges from Delaware to Florida, west to Washington and California. Also occurs in South America.

Like *H. jubatum* the bristles of this species can cause lacerations in the mouths of grazing livestock. In early spring this species affords, before the flowering heads mature, a temporary source of pasture. The grass becomes available in the southern states as

pasture, also in the moist fall months when germination occurs and produces green shoots which may survive the winter.

3a. ***Hordeum vulgare* L. var. *vulgare* Barley**

Map 190

Hordeum sativum hexastichyon, as listed in Daniels' Flora.

Flowers May–June.

This annual cultivated plant is occasionally found in Missouri along roadsides, railroad tracks, and in waste ground, but does not persist. Recent collections from St. Louis (right-of-way of Terminal R. R. Association under the municipal bridge, St. Louis, May 14, 1955, *Muehlenbach* 579) and Greene (open pasture, northeast end of Lake Springfield, southeast of Springfield, May 17, 1958, *Redfearn* 3593) counties are cited here.

Probably native of Asia; introduced and naturalized throughout the United States and Canada.

The dried straw from the cultivated barley is used principally in Europe for pulp in papermaking.

3b. ***Hordeum vulgare* var. *trifurcatum* (Schlecht.)**

Alefeld Beardless Barley, Pearl Barley Map 190

Hordeum aegiceras (E. Meyer) Royle

This awnless variety, having the lemmas tipped with a 3-lobed appendage, has been collected as a waif only from Jackson County (fields, Courtney, June 24, 1932, *Bush* 12479).

Excluded species

***Hordeum montanense* Scribn. Meadow Barley**

Hordeum nodosum [of P & S], not L.

Material previously identified as *H. nodosum* is referred in the present treatment to *H. pusillum*.

- a. Glume (excluding awns) about as long as or longer than the spikelet 3. *L. TEMULENTUM*
 a. Glume (excluding awns) obviously shorter than the spikelet b
 b. Lemmas without an awn, mainly 5–10-flowered; rachis (axis) of spike glabrous except on the angles; upper spikelets with the glume longer than the next floret just above the glume; auricles (projections of green tissue) at top of leaf-sheath short and rounded 1. *L. PERENNE*
 b. Lemmas usually with an awn, 5–20-flowered; rachis (axis) of spike roughened on the upper side away from the spikelets; upper spikelets with the glume not longer than the next floret just above the glume; auricles (projections of green tissue) at top of leaf-sheath long and pointed 2. *L. MULTIFLORUM*

1. ***Lolium perenne* L.** Perennial Rye Grass,
 English Rye Grass Map 191
 Flowers May–August.

Fields, meadows, and waste ground. Scattered over the state. Relatively few records of this species have been found in the state, and more intensive collecting is necessary, although it is probable that it occurs in every county.

Native of Europe; introduced into North America, where it is found from Newfoundland to Alaska, southward throughout most of the United States.

The spikelets are mainly 5–6 mm. long. This is a perennial grass, which, because of the large amount of pollen shed by it, may become a serious cause of hay fever in certain areas, such as on the Pacific coast.

This grass tolerates dry conditions. It is often planted in the spring or fall to produce a temporary new lawn, which may be spaded over as a green manure during the same or following year just before the seeding begins for a permanent lawn. This species and *L. multiflorum*, Italian Rye Grass, are important in the southern states for winter forage. In the United States they are used to some extent for producing meadows, pastures, and lawns.

2. ***Lolium multiflorum* Lam.**
 Italian Rye Grass Map 192

Lolium perenne var. *italicum* (A. Braun) Parnell
 Flowers May–August.

Fields, meadows, and waste ground.

Native of Europe; introduced and naturalized in North America from Newfoundland to Alaska, south to Virginia and California.

Missouri material may be divided as follows:

- Spikelets 10–20-flowered; glume of lowest spikelets often longer than the next floret just above the glume 2a. *L. MULTIFLORUM* var. *MULTIFLORUM*
 Spikelets 5–9-flowered; glume of all the spikelets shorter than the next floret just above the glume.
 2b. *L. MULTIFLORUM* var. *DIMINUTUM*

- 2a. ***Lolium multiflorum* var. *multiflorum***

Map 192

The commoner variety, scattered in Missouri. The spikelets (excluding the awns) are 5–7 mm. long.

- 2b. ***Lolium multiflorum* var. *diminutum* Mutel.**

Map 192

Known from Buchanan (*Steyermark 70116*), Jasper (*Palmer 2408*), and Howell counties.

This variety has sometimes been confused by collectors with *Festuca elatior*.

Lolium multiflorum is more commonly cultivated than

PLATE NO. 32

L. perenne. It is used chiefly to produce temporary lawns and to produce a rapid start until the more permanent grass species take over. It is often seeded along shoulders and banks bordering new highways, and sown in seed mixtures for parks or public grounds where an early new growth is desired. It is somewhat important as a cause of hay fever.

3. ***Lolium temulentum*** L. Darnel Map 193
Flowers May–August.

Missouri material is represented by two varieties:

- Lemmas not awned 3a. *L. TEMULENTUM*
var. *TEMULENTUM*
Lemmas awned 3b. *L. TEMULENTUM*
var. *MACROCHAETON*

3a. ***Lolium temulentum*** var. ***temulentum***

Map 193

Fields and waste ground. Known mostly from western Missouri in Platte, Jackson, and McDonald

counties, and from St. Louis County (*Muehlenbach 1411*).

Native of Europe; introduced into North America, where it extends from Quebec and Minnesota, south to Georgia, Louisiana, and Texas, and from Idaho and Washington south to California and Arizona.

3b. ***Lolium temulentum*** var. ***macrochaeton***

A. Br.

Map 193

Known only from St. Louis County (freight station of the Wabash Railroad, south of Carr Street, St. Louis, May 30, 1958, *Muehlenbach 1398*).

This grass is suspected of causing hay fever during its flowering season. It contains a poisonous alkaloidal substance which is toxic both to human beings and to livestock. The poisonous property is stated to become active only when the plant is infected by a parasitic fungus.

Tribe IV. **AVENEAE**

In this tribe the spikelets are usually on stalks (pedicels), are usually 2- or more-flowered, the glumes are as long as or longer than the lowest lemma, the awn on the lemma, if present, is dorsal (on the back), and the spikelets are articulated usually above, sometimes below, the glumes.

27. ***Koeleria*** Pers.

Koeleria cristata (L.) Pers.

Crested Hair Grass

Map 194

Flowers late May–July.

Occurs in prairies and fields. So far as available records indicate, this species is absent from the north-eastern half of the state, the southeastern lowland section, and from most of the southern and eastern Ozarks.

Ranges from Quebec to British Columbia, south

to Delaware, Ohio, Indiana, Missouri, Texas, California, and Mexico.

In the western part of its range the grass is believed to be an important cause of hay fever during July to September.

The densely fine-pubescent rachis helps to distinguish this genus from *Sphenopholis* in which the rachis is glabrous or at most slightly scabrous.

28. ***Sphenopholis*** Scribn. Wedge Grass

The spikelets are articulated below the glumes, and ordinarily 2-flowered, rarely with a 3rd rudimentary flower.

These are all perennial, spring-flowering species, and all afford good early grazing.

- a. Second (upper) lemma scabrous above the middle; anthers 1–2 mm. long 3. *S. NITIDA*
a. Second (upper) lemma glabrous throughout; anthers 0.3–0.8 mm. *b*
b. Inflorescences loosely flowered, the branches and pedicels visible; spikelets 3–4.2 mm. long; lemmas acute or nearly acute; second glume acute or nearly acute, narrowed at tip 2. *S. INTERMEDIA*
b. Inflorescence compact with crowded dense clusters of spikelets, the branches and pedicels mostly

Plate no. 33. 1. *Trisetum flavescens*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{3}{4}$. 2. *Trisetum pensylvanicum*; a. Panicle, $\times \frac{3}{4}$; b. 194 *Koeleria cristata* (Crested Hair Grass)195 • *Sphenopholis obtusata* var. *obtusata*
195 □ *Sphenopholis obtusata* var. *lobata*196 *Sphenopholis intermedia*

hidden by the spikelets; spikelets 2.5–3 mm. long; lemmas rounded at tip or with a hood-like arching tip; second glume rounded and hood-like at tip I. S. OBTUSATA

1. ***Sphenopholis obtusata*** (Michx.) Scribn.

Map 195

Flowers May–July.

Prairies, rocky open ground, and bluffs.

Throughout Missouri.

The variations of this species range from Florida to Arizona, Mexico, and California, north to Maine, Ontario, Minnesota, North Dakota, Alberta, and British Columbia.

Missouri material may be distinguished as two forms:

Leaf-blades and their leaf-sheaths glabrous, or at most somewhat scabrous 1a. *S. OBTUSATA* var. *OBTUSATA*

Leaf-blades or their leaf-sheaths more or less pubescent 1b. *S. OBTUSATA* var. *LOBATA*

1a. ***Sphenopholis obtusata* var. *obtusata***

Map 195

This is the commoner variation in Missouri and occurs throughout the state.

1b. ***Sphenopholis obtusata* var. *lobata*** (Trin.)

Scribn.

Map 195

Sphenopholis obtusata var. *pubescens* (Scribn. & Merr.)

Scribn. [G, P & S]

This is found mainly in southern and central Missouri, extending north to Pike, Monroe, and Carroll counties.

Sphenopholis obtusata is separated into three varieties in *Gray's Manual*, eighth edition. Too much intergradation and lack of correlation exist, however, as regards the amount of branching of the panicle, its relative length and thickness, and degree of tightness, density, and shape. Consequently, the plants with pubescent leaf-sheaths or blades have been placed together in one category, those with glabrous sheaths

and blades in the other.

Sphenopholis obtusata or other species of the genus is occasionally confused with *Koeleria cristata*. The two genera are easily distinguished, however, *Koeleria* having the rachis of the inflorescence densely fine-pubescent and *Sphenopholis* having it glabrous or slightly scabrous. The spikelets articulate above the glumes in *Koeleria*, so that the glumes remain, whereas in *Sphenopholis* the spikelets articulate below the glumes and fall as a whole.

2. ***Sphenopholis intermedia*** Rydb.

Map 196

Flowers May–July.

Rich or rocky woodland, moist open ground, low wet woodland and moist bluffs along streams. Throughout Missouri.

Ranges from Newfoundland to Alaska, south to Florida and west to the Pacific.

This species is predominantly a woodland inhabitant as contrasted with *S. obtusata* var. *obtusata* and var. *lobata* which are more commonly found in prairies, fields, and open ground.

3. ***Sphenopholis nitida*** (Biehler) Scribn.

Map 197

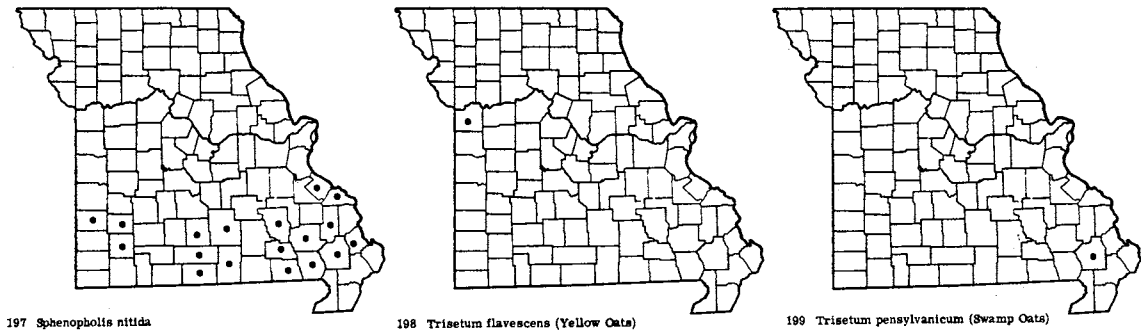

Flowers April–July.

Rocky or sandy open woods of southern Missouri northeast to Ste. Genevieve County.

Ranges from Florida to Texas, north to Massachusetts, Vermont, New York, Ontario, Michigan, Illinois, and Missouri.

This species is found usually in acid soils in regions of sandstone, chert, or granite.

Spikelets in some Missouri specimens may attain 4 mm. in length and the lower lemma a length of 3 mm. The leaf-sheaths and leaf-blades in this species are usually more or less pubescent.

29. **Trisetum** L.

The spikelets are articulated both above and below the glumes in this genus.
Growing in water of small spring-fed creeks; lemmas finely papillose-scabrous; spikelets mainly 2-flowered (rarely 3-flowered); anthers about 1 mm. long 2. **T. PENSYLVANICUM**
Dry soil of fields or roadsides; lemmas glabrous; spikelets 3-4-flowered; anthers 2.5-3 mm. long . 1. **T. FLAVESCENS**

- 1. **Trisetum flavescens** (L.) Beauv.
Yellow Oats Map 198
Flowers late May-July.

Known only from Jackson (June 6, 1891, *Bush*, in U. of Mo. herb.) and Pike (Sept. 29, 1911, *Davis* 226) counties. The *Davis* collection was originally filed under *Arrhenatherum elatius*.

Native of Europe; introduced into the United States, extending from Vermont and New York to Washington, south to Mississippi, Missouri, and Kansas.

- 2. **Trisetum pensylvanicum** (L.) Beauv.
Swamp Oats Map 199
Flowers April-May.

Known only from Stoddard County in southeastern Missouri (along spring-fed creek near junction of Crowley Ridge and lowland, bordered by sandy wooded ravine slopes, T25N, R11E, northwest ¼ sect. 6, 3½ mi. southeast of Bloomfield, April 25, 1955, *Steyermark* 78285).

Ranges from Massachusetts to Ohio, south to Florida, Alabama, and Louisiana.

A very rare species, only recently found in the state, where it was growing in the water of a creek in which Alder (*Alnus serrulata*) occurred. It is a very early-flowering species, by June apparently having matured its seeds and disappearing from the location in which it occurred earlier.

30. **Aira** L. Hair Grass

Spikelets 2-flowered. Small annual grasses with the leaf-blades very short and narrow.

- Aira elegans** Willd. Hair Grass Map 200
Flowers May-June.

Dry sterile soil along roadsides and waste ground, where known from St. Louis County (on the embankment of the Mississippi River, north of the municipal bridge, opposite Grunden Martin Mfg. Co., St. Louis, May 13, 1956, *Muehlenbach* 885) and Oregon County (dry roadside, 4 mi. north of Thayer,

June 11, 1958, *Kucera* 2623).
Native of Europe; introduced into the United States, extending from New Jersey to Florida and Texas, and in California and Oregon.

The rounded-ovoid panicle is very much branched, open, and spreading with tiny spikelets scattered at the ends of the delicate, hairlike branches.

31. **Avena** L. Oats

Spikelets 2-3-flowered. Annual grasses with nodding spikelets in our local species.

- Lemma glabrous, without an awn or the awn straight; spikelets 2-flowered 2. **A. SATIVA**
Lemma with brown or white hairs at the base and usually on the back, with a long awn bent near its middle; spikelets 3-flowered 1. **A. FATUA**

200 *Aira elegans* (Hair Grass)201 *Avena fatua* (Wild Oats)202 *Avena sativa* (Oats)1. *Avena fatua* L. Wild Oats

Map 201

Flowers June–October.

Occasionally found in gardens and waste ground in St. Louis (right-of-way of Mo. Pacific R. R. north of Elwood St., St. Louis, June 13, 1954, *Muehlenbach* 153), Boone (garden, Columbia, July 5, 1910, collector unknown), and Jackson (Sheffield, June 22, 1905, *Bush* 3025) counties.

Native of Europe; introduced into North America, extending from Newfoundland to British Columbia, south to Massachusetts, Pennsylvania, Tennessee, Missouri, New Mexico, and Mexico.

On the Pacific Coast, this species is regarded as an important cause of hay fever during its flowering season from July to September. The seeds of this species are used for food by Indians in the western United States.

2. *Avena sativa* L. Oats

Map 202

Avena fatua var. *sativa* (L.) Haussknecht*Avena nuda* L.

Flowers May–November.

Along roadsides, railroad tracks, and waste ground. This is much more common in Missouri than *A. fatua* and is scattered throughout the state.

Probably native of Europe.

It is the commonly cultivated oat, usually sown for early feed and for crop rotation, especially cultivated in the north central states of the Corn Belt. It is also sown on newly graded highways to prevent washing of the soil.

Dried straw of this species is used principally in Europe as pulp for papermaking.

Avena nuda L., the naked oat, with a grain which readily separates from the lemma and palea, is here included with *A. sativa* L.

32. *Arrhenatherum* Beauv. Oat Grass

Tall perennial grasses with loose narrow panicles. Spikelets 2-flowered, the lower one staminate (male) with a long bent awn, the upper floret perfect with only a short awn on the lemma or merely pointed.

Arrhenatherum elatius (L.) Mert. & Kochvar. *elatius* Tall Oat Grass

Map 203

Flowers late May–August.

Fields and waste ground. Known only from Jasper and Boone (open ground, field crop plots, University of Missouri farms, August 1, 1945, *W. E. Maneval*) counties.

Native of Europe; introduced into North America, extending from Newfoundland to British Columbia, south to Georgia, Louisiana, New Mexico, and California.

This grass is cultivated in the cooler and more moist regions of the northern United States as a meadow grass.

Plate no. 34. 1. *Distichlis spicata*; a. Plant, $\times \frac{2}{5}$; b. Floret, $\times 2$. 2. *Distichlis stricta*; a. Staminate (σ) plant, $\times \frac{1}{5}$; b. 203 *Arrhenatherum elatius* var. *elatius* (Tall Oat Grass)204 *Holcus lanatus* (Velvet Grass)205 • *Danthonia spicata* var. *spicata* (Wild Oat Grass)
205 □ *Danthonia spicata* var. *longipila*33. *Holcus* L. Velvet Grass

***Holcus lanatus* L.** Velvet Grass
Flowers May–July.

Map 204

Along railroads and waste ground, where known from Jackson, Vernon, and Jasper counties of western Missouri.

Native of Europe; introduced into North America, ranging from Newfoundland to Ontario, Michigan, and Iowa, south to Georgia and Louisiana; also

in many Rocky Mountain and Pacific States.

The grass was introduced as a forage plant, where it has been used, principally in the southern states. It is sometimes a cause of hay fever in regions where it is more abundant, especially in California and Oregon. Sometimes it can poison livestock when eaten in a fresh or wilted stage, because of the prussic acid produced.

34. *Danthonia* DC. Wild Oat Grass

Spikelets usually 5–8-flowered in the local species (except for 1–12-flowered spikelets on some of the axillary spikelets), the florets crowded into a column, with the uppermost floret imperfect.

***Danthonia spicata* (L.) Beauv.** Poverty Grass,
Wild Oat Grass
Flowers May–August.

Map 205

Most frequently found in dry acid soil of upland woods and on wooded dry ridges and slopes overlying sandstone, chert, or granitic rocks; also on rocky open glades of these types of rocks, and in rocky acid-soil prairies. Absent only from northwestern and west central and extreme southeastern Missouri.

Missouri material falls into two categories:

Column of flowers $\frac{3}{4}$ length to equaling length of the glumes; inflorescence with mainly 2–15 spikelets; glumes firm, with 3–5 prominent nerves.

1a. *D. SPICATA* var. *SPICATA*

Column of flowers $\frac{1}{2}$ to $\frac{3}{5}$ length of the glumes; inflorescence relatively fewer-flowered, with 3–7 scattered spikelets; glumes thin and more or less transparent, without nerves or the nerves very faint 1b. *D. SPICATA* var. *LONGIPILA*

1a. ***Danthonia spicata* var. *spicata*** Map 205
This is the common variety in the state.

Ranges from Quebec to Minnesota, south to Florida, Alabama, Tennessee, and Arkansas.

1b. ***Danthonia spicata* var. *longipila***
Scribn. & Merr. Map 205

Future collecting may show this variety to occur over a broader range of counties; at present known from a few scattered places.

Ranges from North Carolina and Alabama to New Mexico, north to Connecticut, Pennsylvania, Kentucky, Missouri, and Kansas.

The plants occur characteristically in scattered small clumps, the dried basal leaves persisting as curled and twisted blades. Both variations exhibit a characteristic curling or curving and inrolling of the margins of the basal leaves.

Two kinds of spikelets are found in this grass: the

Plate no. 35. 1. *Calamagrostis inasperata*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c. Glumes, $\times \frac{7}{12}$. 2. *Danthonia spicata*; a. Plant, $\times \frac{3}{8}$; b. Cleistogene, $\times \frac{3}{4}$; c. Floret, $\times \frac{3}{4}$; d. Spikelet, $\times \frac{3}{4}$. 3. *Calamagrostis canadensis* var. *canadensis*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{7}{12}$; c. Glumes, $\times \frac{7}{12}$. 4. *Calamagrostis canadensis* var. *Macouniana*; a. Floret, $\times \frac{7}{12}$; b. Glumes, $\times \frac{7}{12}$. 5. *Calamagrostis inexpansa*; a. Panicle, $\times \frac{3}{4}$; b. Glumes, $\times \frac{7}{12}$; c. Floret, $\times \frac{7}{12}$.

PLATE NO. 35

206 • *Calamagrostis canadensis* var. *canadensis* (Bluejoint)
206 x *Calamagrostis canadensis* var. *Macouniana*

207 *Calamagrostis inexpansa* var. *brevior*

208 *Calamagrostis inasperata*

ones in the visible inflorescence which terminates the culms have 5-8 florets which usually do not open when flowering (cleistogamous), while the other kind of spikelets are hidden in the leaf-sheaths and have 1-12 florets (those of the basal leaves with usually 1 floret, those from the upper axils of the leaves with

as many as 12). For more details on this type of variation, see Weatherwax: Cleistogamy in two species of *Danthonia*. Bot. Gaz. 85: 104-9. 1928; Chase: Axillary cleistogenes in some American grasses. Am. Jour. Bot. 5: 254-58. 1918.

Tribe V. AGROSTIDEAE

The grasses of this tribe are usually 1-flowered (except 2-flowered in some species of *Sporobolus*, *Agrastis*, and *Muhlenbergia*). The glumes are often longer than the lower lemma. Articulation of the spikelets is usually above the glumes, but in *Cinna* and *Alopecurus* (of our local genera) the articulation is below the glumes.

35. *Calamagrostis* Adans. Reed Bent Grass

Perennial grasses with a many-flowered, branched, open or contracted panicle.

- a. Panicle loose and open, at least during time of flowering 1. *C. CANADENSIS*
- a. Panicle contracted or spike-like during time of flowering b
- b. Leaf-blades mainly 1-4 mm. wide; spikelets 3-4.5 mm. long; awn of lemma straight or slightly bent, not twisted, arising at about the middle of the lemma 2. *C. INEXPANSA* var. *BREVIOR*
- b. Leaf-blades 5-11 mm. wide; spikelets 5-5.5 mm. long (3.75-5 mm. in Mo. material); awn of lemma bent near the middle, twisted near the base (when dry), arising near the base of the lemma 3. *C. INSPERATA*

- 1. ***Calamagrostis canadensis* (Michx.) Beauv.**
Bluejoint Map 206
Flowers late May-August.
Missouri material falls into two categories:

Spikelets 2.8-3.8 mm. long; glumes longer than the lemma, acute to acuminate 1a. *C. CANADENSIS*
var. *CANADENSIS*

Spikelets 2.2-2.8 mm. long; glumes as long as lemma or slightly longer, obtuse or somewhat acute. 1b. *C. CANADENSIS* var. *MACOUNIANA*

- 1a. ***Calamagrostis canadensis* var. *canadensis***
Map 206

Wet meadows and swales in prairies and prairie remnants along railroads. Scattered in parts of north-

ern, central, and eastern Missouri, southeast to Cape Girardeau County.

Ranges from Newfoundland to Alaska and British Columbia, south to Delaware, Pennsylvania, West Virginia, Ohio, Indiana, Illinois, Missouri, Nebraska, New Mexico, and California.

- 1b. ***Calamagrostis canadensis* var. *Macouniana***
(Vasey) Stebbins Map 206
Northern and central Missouri south to Jackson, Lafayette, Randolph, and Ralls counties.

Ranges from Newfoundland to New Jersey and Pennsylvania, Michigan to Saskatchewan, west to Alberta and Washington, south to Missouri, Nebraska, and Wyoming.

- 2. **Calamagrostis inexpansa** Gray var. **brevior**
(Vasey) Stebbins Map 207
Flowers June–August.
Swales in sandy open ground and low wet ground, sometimes in or bordering woodland where found in Jackson, Texas, and Barton (swales in sandy open ground, border of woods near Bakers, July 19, 1955, *Palmer 60766*) counties.
Ranges from Newfoundland to British Columbia, south to New Hampshire, New York, Ontario, Michigan, Indiana, Wisconsin, Iowa, Missouri, Nebraska, New Mexico, Arizona, and California.
- 3. **Calamagrostis insperata** Swallen Map 208
Flowers June–September.
Inhabits rocky wooded ravines and open grassy

rocky slopes of bluffs in the southern part of the Ozarks, where known from Ozark County (lower chert slopes in ravine in Blue Springs Game Refuge, Gardner National Forest, Sept. 12, 1936, *Steyermark 20043*) and Douglas County (rocky, grassy, open cherty limestone slopes at east end of bluffs along Indian Creek, near Holy Cliff, 3½ mi. northeast of Topaz, July 19, 1937, *Steyermark 23350*).
Range is limited to Ohio (where first discovered) and Missouri.
Dr. Van Schaack (Rh. 56: 43. 1954) has reported on the occurrence of this species in Missouri, and on the variability shown in length of spikelets, width of leaves, and length of ligule as compared with the material originally described from Ohio.

36. **Calamovilfa** (Gray) Hack.

Tall perennial grasses with strongly creeping, scaly rhizomes, and loosely spreading panicles. The leaf-blades have a pale straw color. The ligule is a ring of short hairs.

- Calamovilfa longifolia** (Hook.) Scribn. var.
longifolia Long-leaved Reed Grass, Sand
Reed Grass Map 209
Flowers July–September.
Low and sandy open ground, scattered in four counties (St. Louis, Jefferson, Jackson, and Clay) of central Missouri.

Ranges from Ontario to British Columbia, south to Indiana, Illinois, Missouri, Kansas, and Colorado.
As the grass spreads rapidly by means of its underground stems, it has been planted in sandy blowouts and other similar areas to keep the sand from shifting or covering over areas.

37. **Agrostis** L. Bent Grass

- a. Awn present, attached to lemma *b*
 - b. Inflorescence dense, contracted, the spikelets and branches remaining close to main axis. 2. *A. INTERRUPTA*
 - b. Inflorescence open, the spikelets on branches spreading out from main axis *c*
 - c. Awns conspicuous, longer than spikelet, 5–10 mm. long *d*
 - d. Leaves 2–6 mm. wide; awns 5–8 mm. long; palea present, half to about as long as lemma. 1. *A. SPICA-VENTI*
 - d. Leaves about 1 mm. wide; awns around 10 mm. long; palea absent or very minute. 5. *A. ELLIOTTIANA*
 - c. Awns inconspicuous, shorter than spikelet, 3 mm. or less long *e*
 - e. Leaf-blades mainly 1–2.5 (–3) mm. long; ligule deeply and irregularly cut; branches of inflorescence dividing near the tip or above the middle; spikelets mainly purplish, crowded near tips of branches; plants mostly of sunny open places, mostly flowering April–June 6. *A. HYEMALIS*
 - e. Leaf-blades mainly 3–6 mm. (rarely less) wide; ligule entire, oblong, rounded at tip; branches of inflorescence dividing near or below the middle; spikelets mainly green, appearing midway or lower on the branches; plants mostly growing in woodland, usually flowering July–October 7. *A. PERENNANS*
- a. No awn present on any part of spikelet *f*
 - f. Leaf blades mainly 1–2.5 (–3) mm. wide; ligule deeply, finely, and irregularly cut in upper half; branches of inflorescence forking or dividing only near or towards the tip; spikelets crowded at or near the tips of the branches 6. *A. HYEMALIS*
 - f. Leaf-blades mainly 3–8 mm. (rarely less) wide; ligule entire, rounded at tip (too old or damaged

209 *Calamovilfa longifolia* var. *longifolia* (Long-leaved Reed Grass)210 *Agrostis spica-venti*211 *Agrostis interrupta*

- leaves may appear otherwise); branches of inflorescence forking or dividing near or below the middle; spikelets appearing midway or lower on the branches g
- g. Palea at least half as long as lemma; plants with underground scaly rhizomes or creeping leafy stems h
- h. Ligule of lower and middle leaves longer than broad or as long as broad; rounded at tip, 2-6 mm. long; leaves 3-8 mm. wide; inflorescence with the branches flower-bearing to below the middle 3. *A. ALBA*
- h. Ligule of lower and middle leaves broader than long, truncate at tip, 0.5-1.5 mm. long; leaves 1-5 mm. long; inflorescence with the branches flower-bearing mainly above the middle 4. *A. TENUIS*
- g. Palea absent or very minute; plants tufted, without underground rhizomes or creeping leafy stems 7. *A. PERENNAN*

1. *Agrostis spica-venti* L.

Map 210

Flowers May-July.

Along railroads in St. Louis (Right-of-way of Burlington R. R. south of Merchants Bridge, St. Louis, June 5, 1954, *Muehlenbach 112*) and Jackson (along railroads, becoming common, June 11, 1891, *Bush 1890*) counties.

Native of Europe; introduced into the United States, ranging from Maine to Michigan, south to Delaware, Maryland, Ohio, and Missouri.

An annual grass.

2. *Agrostis interrupta* L.

Map 211

Flowers late June-July.

Known only from a collection from St. Louis County (Missouri Botanical Garden, St. Louis, June 30, 1904, *Kellogg*).

Native of Europe; introduced into the United States where known only from Missouri and on the Pacific Coast.

An annual grass.

X 3. *Agrostis alba* L. Redtop

Map 212

Agrostis stolonifera var. *major* (Gaud.) Farw. [BB]

Agrostis stolonifera [of P & S], not L.

Flowers June-August.

Fields, along railroads, and waste ground, along spring branches, wet meadows, swampy prairies, ditches, in damp thickets, alluvial ground along streams, crevices of rocks in stream beds, and moist open places.

Ranges from Newfoundland to Yukon, south to Georgia, Louisiana, New Mexico, Arizona, and California; Eurasia.

The foliage is bluish-green. This grass and timothy (*Phleum pratense*), flowering mainly during June and July, are responsible for causing most of the hay fever cases occurring at this time in the eastern states.

Because of the dense underground root system, this grass makes a good soil binder and is used in preventing erosion on unprotected slopes. Due to its success in growing in acid soils, it has been used as a forage crop on poor soils and in worn-out fields. It is often found in lawn seed grass mixtures, being of value as a temporary quick-germinating green cover until the more permanent Colonial Bent or Kentucky Blue Grass becomes established.

A variety of this, the Creeping Bent (*A. alba* var. *palustris* [*A. stolonifera* var. *compacta*]) has leaf-blades 1-3 (rarely 5) mm. wide and a compactly-flowered

Plate no. 36. 1. *Agrostis spica-venti*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{3}{4}$; c. Glumes, $\times \frac{3}{4}$. 2. *Agrostis interrupta*; a. Panicle, $\times \frac{3}{8}$; b. Floret, $\times \frac{3}{4}$; c. Glumes, $\times \frac{3}{4}$. 3. *Calamovilfa longifolia*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{3}{4}$; c. Spikelet, $\times \frac{3}{4}$.

PLATE NO. 36

212 *Agrostis alba* var. *alba* (Redtop)213 *Agrostis tenuis* (Colonial Bent)214 *Agrostis Elliottiana*

inflorescence with appressed, closely ascending branches. It forms dense mats by virtue of the creeping rooting stolons. Since it is resistant to salt spray, Creeping Bent is sometimes used as a lawn grass near the seashore. It is also commonly used on golf courses for putting greens, but requires cool moist conditions to keep it going.

4. ***Agrostis tenuis*** Sibth. Colonial Bent,
Rhode Island Bent Map 213
Agrostis capillaris L.
Flowers June–September.
Scattered over the state.

Fields, waste ground, roadsides, and damp thickets. Native of Europe; introduced into the United States, ranging from Labrador to British Columbia, south to North Carolina, Ohio, Indiana, Missouri, North Dakota, and Oregon.

This grass is much used for lawns, sports turf, and pastures, and many improved strains have been developed. It does well in full sun. It is a good grass for cool, moist climates, but requires constant attention in watering, fertilizing, close mowing, and disease control to keep it thriving.

Like *A. alba*, this species is responsible for some hay fever cases.

5. ***Agrostis Elliottiana*** Schultes Map 214
Flowers April–June.

Occurs in sterile acid soils exposed to the sun, often on sandstone, chert, on granite glades, sterile fields and prairies, open sandy and cherty soils, and sometimes along leached or eroded sterile slopes, in the Ozark region of southern and central Missouri north to Lafayette, Morgan, Montgomery, and Pike counties. Absent from the southeastern lowland section.

Ranges from Georgia to Texas, north to Virginia, Kentucky, Indiana, Illinois, Missouri, and Kansas. An annual grass.

6. ***Agrostis hyemalis*** (Walt.) BSP. var. ***hyemalis***
Hair Grass, Tickle Grass, Winter Bent Grass

Map 215

Agrostis scabra [of P & S], not Willd.

Flowers April–June.

Occurs in prairies, fields, meadows, roadsides, and occasionally open woods throughout Missouri.

Ranges from Florida to Texas to Massachusetts, New York, Pennsylvania, Indiana, Illinois, Wisconsin, Minnesota, and Kansas.

When mature the entire inflorescence breaks off from the plant and is carried away by the wind in the manner of various tumbleweeds.

This species varies in the diameter of the inflorescence, increasing in size with maturity. Under favorable conditions of growth the culms and inflorescences develop into luxuriant specimens which are in contrast to plants growing in drier more exposed situations.

7. ***Agrostis perennans*** (Walt.) Tuckerm.
Upland Bent Map 216
Flowers July–October.

Found on upland open wooded slopes, low or rich woods, moist limestone bluffs, exposed sandstone rocks, prairie swales, fields, margins of streams and ponds, and moist open ground. Throughout Missouri except in the northwestern section, where apparently absent or local.

Two varieties may be recognized:

Most pedicels (stalks of spikelets) shorter than their spikelets; culms (stems) firm and erect with 3–6 leaves; spikelets more or less uniform,

PLATE NO. 37

215 *Agrostis hyemalis* var. *hyemalis* (Hair Grass)216 • *Agrostis perennans* var. *perennans* (Upland Bent)
216 □ *Agrostis perennans* var. *aestivalis*217 • *Cinna arundinacea* var. *arundinacea* (Wood Reed Grass)
217 □ *Cinna arundinacea* var. *inexpansa*

2–3 mm. long; branches of inflorescence ascending to spreading; frequent in open ground, margins of streams, and moist fields, as well as woodland.

7a. *A. PERENNANS* var. *PERENNANS*

Most pedicels 1–3 times longer than their spikelets; culms weak, erect to sprawling with 5–10 leaves; spikelets often 1.5–2 mm. long, variable in size; branches of inflorescence mainly widely spreading; inflorescence with a loose and open appearance; frequent in woodland, on shaded slopes or banks. 7b. *A. PERENNANS* var. *AESTIVALIS*

7a. *Agrostis perennans* var. *perennans* Map 216

This has a stiffer inflorescence and is more often found in more exposed situations. However, there is

great intergradation between typical var. *perennans* and var. *aestivalis* in the various characters used to separate them.

Ranges from Quebec to Minnesota, south to Florida, Louisiana, and Texas.

7b. *Agrostis perennans* var. *aestivalis* Vasey
Map 216

Agrostis Schweinitzii Trin. [Rickett]

Scattered over the state. More frequent on wooded slopes and banks, rich shaded woods, and along streams.

Ranges from Quebec to Wisconsin, south to North Carolina, Tennessee, Mississippi, Missouri, and Kansas.

38. *Cinna* L. Wood Reed Grass

Tall perennial grasses with a many- and closely-flowered, gray-green to purple-tinged, often drooping inflorescence with spreading to rather ascending branches. Ligule conspicuous, membranous, transparent.

Cinna arundinacea L. Wood Reed Grass

Map 217

Flowers July–October.

Wet woodland, meadows, damp thickets, and wooded banks of streams and ponds. Throughout Missouri.

Missouri material falls into two categories:

Branches of inflorescence ascending or spreading; spikelets 4.5–6 mm. long; both glumes scabrous-hispid. 1a. *C. ARUNDINACEA* var. *ARUNDINACEA*

Branches of inflorescence closely contracted; spikelets 3.7–4.2 mm. long; 1st glume glabrous except for the scabrous keel. 1b. *C. ARUNDINACEA* var. *INEXPANSA*

1a. *Cinna arundinacea* var. *arundinacea* Map 217

This is the common type encountered in the state.

Ranges from Maine and Quebec to Ontario and Minnesota, south to Georgia, Tennessee, Arkansas, and Texas.

1b. *Cinna arundinacea* var. *inexpansa*

Fern. & Gris.

Map 217

Known from six counties in the western half of the state south of the Missouri River. Probably much more common in the southern part of the state.

Ranges from Virginia to Louisiana, Missouri, and Oklahoma. There is considerable intergradation in the varieties here treated, with sometimes little or no correlation apparent.

PLATE NO. 38

218 *Alopecurus pratensis* (Meadow Foxtail)219 *Alopecurus aequalis* (Floating Foxtail Grass)220 *Alopecurus carolinianus*

39. *Alopecurus* L. Foxtail

Low annual or perennial grasses with dense cylindric inflorescences. The ligule is membranous. The spikelets are strongly flattened laterally.

- a. Spikelets about 5 mm. long; awn protruding about 5 mm.; glumes 3.5 mm. or more long, lateral nerves conspicuous 1. *A. PRATENSIS*
- a. Spikelets 2-3 mm. long; awn not protruding from spikelet or protruding 4 mm. at most; glumes 3 mm. or less long, the lateral nerves faint or absent b
- b. Awn attached near base of lemma, twisted or bent, protruding 2-4 mm. beyond the lemma; anthers 0.4-0.6 mm. long; annuals 3. *A. CAROLINIANUS*
- b. Awn attached about halfway up the lemma, straight, not protruding or protruding at most 1 mm. beyond the lemma; anthers 0.5-1 mm. long; perennials 2. *A. AEQUALIS*

1. *Alopecurus pratensis* L. Meadow Foxtail

Map 218

Flowers May-August.

Occurs in fields, meadows, and waste ground.

Known only from St. Louis and Boone counties.

Native of Europe; introduced into North America, ranging from Newfoundland to Ontario, south to Georgia, Indiana, Missouri, and Kansas; and from Alaska to Idaho and Oregon.

A perennial grass, sometimes planted for its palatable and nutritious forage value in meadows. During its flowering season it can be a cause of hay fever, especially in some of the New England states, where more abundant. It flowers several weeks earlier than timothy (*Phleum pratense*), with which it can be confused.

2. *Alopecurus aequalis* Sobol.

Floating Foxtail Grass

Map 219

Flowers May-September.

Occurs in swampy ground, borders of ponds and sloughs, and wet open ground, in southern and central

Missouri. This is one of the grasses occasionally found around the margins of natural sink-hole ponds in the southern Ozarks.

Ranges from Newfoundland to Alaska, south to Maryland, Ohio, Indiana, Illinois, Missouri, Kansas, New Mexico, Arizona, and California.

It is a perennial species.

3. *Alopecurus carolinianus* Walt.

Map 220

Flowers April-August.

Occurs in meadows, fallow fields, along moist ditches, borders of ponds, sloughs, wet ground, wet depressions in glades, and waste ground. Throughout Missouri.

Ranges from Florida to Texas to New Jersey, Pennsylvania, Ohio, Indiana, Wisconsin, Minnesota, South Dakota, Montana, and Washington.

An annual species. As it does in Indiana, this grass often grows in fallow corn fields associated with other annuals, such as *Poa Chapmaniana*, *Myosurus minimus*, *Draba brachycarpa* and *Myosotis verna*.

40. *Phleum* L. Timothy

Bunch grasses with a dense, cylindric, blue-green inflorescence. The ligule is conspicuous and elongated.

Phleum pratense* L. var. *pratense* f. *pratense

Timothy

Map 221

Flowers May–August.

In meadows, along roadsides, and waste ground. Throughout Missouri.

Native of Europe; introduced and naturalized throughout North America.

A short-lived perennial grass having a thickened or bulblike base. It is the chief dry grass and hay crop of the United States. It is sown usually in the fall, and will grow on a wide variety of soils. Name originated from Timothy Hanson of Mary-

land who introduced the grass from Europe about 1720.

During its main flowering season in June and July, it sheds great quantities of pollen, which are responsible for the grass being one of the worst contributors to hay fever in early summer.

Plants with the spikelets changed to leafy tufts are known as var. *pratense* f. *viviparum* (S. F. Gray) Louis-Marie, and narrower-leaved specimens with the leaf-blades only 2–5 mm. wide and the inflorescence only 3–6 mm. thick are placed in var. *nodosum* (L.) Huds.

41. *Muhlenbergia* Schreb. Muhly

Mostly summer- and fall-flowering perennial grasses (in the local species) with erect or sprawling culms, and slender elongated or loose and open inflorescence. Ligule prominent or nearly lacking. Spikelets usually 1-flowered, occasionally 2-flowered. Fruit closely enveloped by the lemma.

- a. Inflorescence loosely and openly branched, 5–20 cm. wide, broadly ellipsoid or ovoid; spikelets on pedicels (stalks) several to many times length of spikelet (excluding awn) b
- b. Awn 4–20 mm. long projecting from tip of lemma; plant growing in a clump or tuft, lacking any creeping underground stem (rhizome); leaves mainly 10–30 cm. long, 2–4 mm. wide; ligule 2–5 mm. long, triangular 12. *M. CAPILLARIS*
- b. No awn on lemma; plant sending out 1 or more creeping elongated underground stems (rhizome); leaves short, mainly 2–7 cm. long, 1–2 mm. wide; ligule 0.5–1 mm. long, with ragged margin (erose) 2. *M. ASPERIFOLIA*
- a. Inflorescence not loosely and openly branched as described above, but narrow, contracted, dense or many times longer than broad, usually less than 2.5 cm. thick or wide; spikelets either sessile (without stalk) or on short pedicels (stalks) usually shorter than length of spikelet (excluding awn) or on pedicels at most less than twice length of spikelet c
- c. Glumes with their awns 4.5–8 mm. long, much longer than lemma 3. *M. RACEMOSA*
- c. Glumes 0.2–3 mm. long, either shorter than or at most only somewhat longer than lemma d
- d. Glumes mostly 0.1–0.5 mm. (rarely 1–2 mm.) long, 1/7 to less than 1/2 length of the body of the lemma (excluding awn of lemma or glume); culms (stems) rooting at lower nodes, lacking scaly creeping underground stem (rhizomes) e
- e. Commonly found throughout Missouri; glumes about as broad as long, rounded or flat-topped at summit; 2nd glume 0.2–0.5 mm. long; lemma 1.8–2.5 mm. long (excluding awn); awns 2–5 mm. long 11a. *M. SCHREBERI* var. *SCHREBERI*
- e. Rare, known only from Barry Co.; glumes longer than broad, acute to sharp-pointed at tip; 2nd glume 1–2 mm. long; lemma 2.5–3 mm. long (excluding awn); awn 0.3–2 mm. long. 11b. *M. SCHREBERI* var. *CURTISSETOSA*
- d. Glumes 1.4–3 mm. long, from 1/2 length to slightly longer than length of the body of the lemma (excluding awn of lemma); plants either with scaly underground creeping or elongated stems (rhizomes) or growing in a bunch or clump without rhizomes f
- f. Lemma glabrous (without hair) at its base g
- g. Plants growing in a dense clump or tuft without any scaly underground creeping or elongated stems (rhizomes); leaves stiff, 1–2 mm. long, with inrolled margins; edges of limestone bluffs, limestone glades, and loess hills 1. *M. CUSPIDATA*
- g. Plants with scaly underground creeping or elongated stems (rhizomes); leaves not stiff, 2–4 (–7) mm. wide, flat; rocky wooded hills, gravelly places, low banks, and prairies 8. *M. GLABRIFLORA*
- f. Lemma with a beard of hairs at the base fi

- h. Culms (stems) between the nodes, and nodes themselves glabrous, (infrequently minutely scabrous just below nodes in no. 4 [*M. sobolifera*] and no. 6 [*M. brachyphylla*]); key out such exceptions here or in other h i
- i. Ligule nearly obsolete or scarcely showing, less than 0.5 mm. long; anthers 0.8–1 mm. long; spikelets 1.5–2.7 mm. long; lemma 1.7–2.6 mm. long; culms solitary or few, unbranched or very slightly branched; plants usually of dry wooded upland or rocky or non-rocky slopes of hills 4. *M. SOBOLIFERA*
- i. Ligule an obvious protruding membrane about 1 mm. or more long; anthers 0.3–0.8 mm. long; spikelets mostly 2.5–3.8 (rarely 2–2.5) mm. long; lemma 2–3.5 mm. long; culms usually branching from various nodes, usually with many branches; plants usually of moist low slopes along streams, river banks, bluffs, base of bluffs, and gravel bars j
- j. Glumes ovate or ovate-lanceolate, broadest at or below middle, abruptly narrowed to the slender tip, usually shorter than body of lemma (excluding awn of lemma), except in *M. brachyphylla* f. *aristata*; lemma usually awned, the awn mainly 2–8 mm. (rarely 0.5–2 mm.) long 6. *M. BRACHYPHYLLA*
- j. Glumes lanceolate, gradually narrowed from base (where widest) and tapering to a long slender tip, slightly shorter than or nearly equaling the lemma; lemma usually without an awn, or with an awn 4–10 mm. long 7. *M. FRONDOSA*
- h. Culms (stems) below the nodes (turn the plant in natural growing position) more or less pubescent, the nodes themselves glabrous or pubescent k
- k. Glumes ovate or ovate-lanceolate, broadest at or below middle, abruptly narrowed to a slender tip, usually noticeably shorter than lemma (except longer in *M. brachyphylla* f. *aristata*); anthers 0.5–1.5 mm. long l
- l. Spikelets (excluding the awn) 1.5–2.7 mm. long; lemma (excluding the awn) 1.7–2.6 mm. long, usually without an awn 4. *M. SOBOLIFERA*
- l. Spikelets (excluding the awn) 2.5–4 mm. long; lemma (excluding the awn) 2.5–3 mm. long, usually with an awn. m
- m. Nodes themselves hairy; culms and leaf-sheaths usually conspicuously or densely hairy, hairs on leaf-sheaths up to 0.5 mm. long; leaves 5–15 mm. wide; anthers 1–1.5 mm. long 5. *M. TENUIFLORA*
- m. Nodes themselves glabrous; culms and leaf-sheaths mostly glabrous; leaves 3–7 mm. wide; anthers 0.5–0.8 mm. long 6. *M. BRACHYPHYLLA*
- k. Glumes lanceolate, gradually narrowed from above base (where widest) and tapering to a long slender tip, shorter to slightly longer than lemma; anthers 0.3–0.6 mm. long n
- n. Lemmas usually awned, rarely awnless; inflorescence long and slender, flexuous, the branches slender, 12–30 mm. apart; spikelets loosely overlapping, often on pedicels half as long as spikelets; glumes very gradually tapering to the tip, translucent, thin, silvery-green or whitish, mainly shorter than the lemma and unequal to nearly equal 9. *M. SYLVATICA*
- n. Lemmas usually awnless, more rarely with awn up to 10 mm. long; inflorescence stout and stiff, the branches often club-shaped and 10 mm. or less apart; spikelets closely overlapping, short-pedicelled to nearly sessile; glumes more abruptly tapering to the tip from a broader base, opaque, firm, green or purple, mainly as long as the lemma, and mostly equal 10. *M. MEXICANA*

1. ***Muhlenbergia cuspidata*** (Torr.) Muhl.
Plains Muhly Map 222
Flowers July–October.

Characteristic of edges of limestone bluff escarpments bordering limestone glades in the Ozark region, and in the loess hills of northwestern Missouri; in the Ozarks occurring east to Washington and Shannon counties and north to Maries, Morgan, and Henry counties.

Ranges from Michigan to Alberta, south to Ohio, Kentucky, Illinois, Missouri, Oklahoma, and New Mexico.

This species frequents west- to south-facing, hot, dry limestone bluffs in the Ozark section, generally selecting the precipitous margins of the bluffs where it forms dense wiry clumps.

2. ***Muhlenbergia asperifolia*** (Nees & Meyen)
Parodi Scratchgrass Map 223
Flowers late May–September.

Along railroads and in sandy open ground. Known only from St. Louis (freight yard of Burlington R. R. north of Carrie Ave., St. Louis, May 30, 1955, *Muehlenbach* 619), Jackson, and Holt counties.

221 *Phleum pratense* (Timothy)222 *Muhlenbergia cuspidata* (Plains Muhly)223 *Muhlenbergia asperifolia* (Scratchgrass)

Ranges from Illinois, Minnesota, and Saskatchewan to British Columbia, south to Missouri, Texas, and California; also Mexico and South America.

The small spikelets, 1.5 mm. long, are purplish.

3. *Muhlenbergia racemosa* (Michx.) BSP.

Map 224

Flowers August–October.

Alluvial bottomland of the Missouri and Mississippi rivers, prairies, and moist open places, in northern and central Missouri south to Jackson, Osage, Gasconade, and Jefferson counties.

Ranges from Michigan to Saskatchewan, south to Illinois, Missouri, Kansas, and New Mexico, and introduced eastward to New Hampshire.

The dense spikelike panicles vary from 4–20 mm. thick and from greenish to purple.

4. *Muhlenbergia sobolifera* (Muhl.) Trin.

Map 225

Flowers July–October.

Commonly found on dry rocky or rich wooded slopes and upland wooded ridges, in limestone, but also chert, and sandy areas. It often is found in more acid soils in Missouri than the other species of the genus. It also occurs on bluffs and rarely in open situations. Throughout Missouri.

Ranges from New Hampshire to Wisconsin and Iowa, south to Virginia, Tennessee, Arkansas, and Texas.

Missouri material falls into two categories:

- | | |
|---------------------------------------|---|
| Lemmas without an awn . . . | 4a. <i>M. SOBOLIFERA</i> |
| | f. <i>SOBOLIFERA</i> |
| Lemmas with an awn 1–3 mm. long . . . | |

4a. *Muhlenbergia sobolifera* f. *sobolifera*

Map 225

The common type throughout the state.

4b. *Muhlenbergia sobolifera* f. *setigera* (Scribn.)

Deam

Map 225

Known only from Christian County (upland woods along Pine Ridge road, 5 mi. southwest of Chadwick, July 17, 1954, *Palmer 58256*).

This form ranges from Indiana to Missouri, south to Arkansas and Texas.

This species ordinarily has solitary or separated, few, erect unbranched stems with divaricately spreading leaves arranged in two opposite directions. The rhizomes are usually remotely and loosely branched with the rhizomescales 4–6 mm. long. The spikelets are usually pale greenish-white, the glumes whitish.

5. *Muhlenbergia tenuiflora* (Willd.) BSP.

Map 226

Flowers July–October.

Like *M. sobolifera*, this species usually inhabits woodland, being found generally in open rocky woods, limestone wooded slopes, and low woods along streams. It is sometimes found in exposed situations. Found in southern and central Missouri north to Jackson, Boone, and Lincoln counties.

This is a handsome grass with dark green leaves as much as 15 mm. wide, which is the greatest width reached by any of the local species. A height of 1 meter is sometimes attained by the usually unbranched erect culms. The rhizomes are loosely and remotely branched as in *M. sobolifera*, but have scales 5–10 mm. long. The hairs on the culms and leaf-sheaths are more conspicuous and longer (up to 0.5 mm. long on the leaf-sheaths) than in any of the other species in Missouri.

6. *Muhlenbergia brachyphylla* Bush

Map 227

Flowers August–October.

Frequent in low moist woods, river banks, and at the base of bluffs. Throughout Missouri.

Ranges from Indiana to Nebraska, south to Missouri and Texas; reported from Virginia.

224 *Muhlenbergia racemosa*225 • *Muhlenbergia sobolifera* f. *sobolifera*
225 □ *Muhlenbergia sobolifera* f. *setigera*226 *Muhlenbergia tenuiflora*

Missouri material falls into two categories:

Glumes acuminate to shortly aristate or at most with short awns shorter than length of body of lemma (excluding awn of lemma)

6a. *M. BRACHYPHYLLA* f. *BRACHYPHYLLA*

Glumes definitely awned with awns up to 2 mm. long, longer than the length of the body of the lemma 6b. *M. BRACHYPHYLLA* f. *ARISTATA*

6a. ***Muhlenbergia brachyphylla* f. *brachyphylla***

Map 227

The common type encountered throughout Missouri.

6b. ***Muhlenbergia brachyphylla* f. *aristata***

Palmer & Steyermark

Map 227

Known only from the type collection from Pike County (wooded slopes along spring branch at base of high limestone bluff, vicinity of Stillhouse Cave along Clifty Fork of Spencer Creek, T53N, R4W, sect. 5, $1\frac{1}{2}$ – $1\frac{3}{4}$ mi. southeast of Spenceburg, Oct. 7, 1956, *Steyermark 82921*).

There is considerable variation in *M. brachyphylla*. In addition to the variation in the apex of the glumes, the lemma may be only slightly awned, with the awn barely 0.5 mm. long, or the awn may attain a length of 8 mm. The principal terminal panicles are usually exserted, but plants frequently are found with the panicles mostly included within the leaf-sheaths.

The rhizomes are closely branched and bunched as in *M. frondosa* but the median rhizome scales are closely appressed to the surface of the rhizome and are oblong to narrowly ovate.

7. ***Muhlenbergia frondosa* (Poir.) Fern.**

Nimble Will, Satin Grass

Map 228

M. mexicana [of P & S], not (L.) Trin.

Flowers August–November.

Commonly occurring on low wooded slopes, ledges, base of bluffs and muddy banks along streams, gravel bars of small streams, sandy bluffs, prairie swales, moist woods, moist ground near lakes, and occasionally waste ground. In some areas becoming weedy, where difficult to eradicate (see Deam, *Grasses of Indiana*, p. 165, 1929).

Ranges from New Brunswick and Quebec to Ontario and North Dakota, south to Georgia, Tennessee, Missouri, Arkansas, and Texas.

Missouri material falls into two categories:

Lemma without an awn 7a. *M. FRONDOSA* f. *FRONDOSA*

Lemma with an awn 4–10 (–20) mm. long

7b. *M. FRONDOSA* f. *COMMUTATA*

7a. ***Muhlenbergia frondosa* f. *frondosa***

Map 228

Common throughout Missouri, except for lack of records in a number of counties in the southeastern quarter.

7b. ***Muhlenbergia frondosa* f. *commutata***

(Scribn.) Fern.

Map 228

Muhlenbergia mexicana f. *commutata* (Scribn.) Wieg. [P & S]

Infrequently occurring, and scattered in various parts of the state. In a specimen from Wayne County (*Steyermark 6619*) the awn of the lemma is 20 mm. long.

This species has closely branched and bunched

Plate no. 39. 1. *Muhlenbergia asperifolia*; a. Plant, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c. Glumes, $\times \frac{7}{12}$. 2. *Muhlenbergia glabri-flora*; a. 228-A *Muhlenbergia glabriflora*

rhizomes. As compared with *M. brachyphylla*, the median rhizome scales in *M. frondosa* are more loosely arching and ovate instead of narrowly ovate or oblong. The stems sometimes attain a height of 1.3 meters, and vary from erect to sprawling.

8. ***Muhlenbergia glabriflora* Scribn.** Map 228A
Flowers August–October.

Occurs in prairies, moist open soils, and rocky slopes. Scattered in southern and central Missouri, north to St. Louis, Phelps, and Cass counties.

Ranges from Indiana, Illinois, and Missouri, south to Texas; also Maryland, Virginia, and North Carolina.

9. ***Muhlenbergia sylvatica* Torr.** Map 229
Flowers July–October.

Found in swampy meadows in the southeastern Ozarks, in moist thickets bordering meadows, thickets at the base of wooded bluffs, along moist crevices of sandstone or limestone bluffs, open banks bordering woods, and moist rocky woods and slopes bordering streams and occasionally upland woods. Throughout Missouri, except in some sections.

Ranges from Quebec to Ontario, Minnesota, and South Dakota, south to North Carolina, Alabama, Arkansas, and Texas.

Missouri material falls into two categories:

Lemma with an awn 3–15 mm. long. . . .

9a. **MUHLENBERGIA SYLVATICA** var. **SYLVATICA**
f. **SYLVATICA**

Lemma without an awn . . . 9b. **MUHLENBERGIA**

9a. ***Muhlenbergia sylvatica* var. *sylvatica***
f. ***sylvatica***

Map 229

The common one encountered throughout the state. Apparently absent from the southeastern lowland section.

9b. ***Muhlenbergia sylvatica* var. *sylvatica***
f. ***attenuata*** (Scribn.) Palmer & Steyermark

Map 229

Infrequent and scattered throughout the state.

The glumes in *M. sylvatica* are somewhat variable, but are generally shorter than the lemma (some current manuals have confused the situation by indicating in the key that the glumes are nearly or about as long as the lemma), and nearly equal (although stated to be unequal or very unequal in some manuals). The glumes are usually ovate-lanceolate or lanceolate with broad scarious margins (confusion is again created by their description in some manuals as 'linear-lanceolate to linear-attenuate'). The glumes are broader and more abruptly tapering than in *M. mexicana*, a species with which it is often misidentified.

10. ***Muhlenbergia mexicana* (L.) Trin.** Map 230
M. foliosa [of P & S], not (R & S) Trin.

Flowers August–October.

Occurs in damp thickets, moist woods, upland wooded slopes and wooded ravines, wet open swales and meadows, and waste ground.

Rather infrequent, and mostly in western Missouri, locally eastward to St. Louis, Lincoln, and Pike counties.

Ranges from Nova Scotia and Quebec to British

Plate no. 40. 1. *Muhlenbergia sylvatica*; a. Plant, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c. Glumes, $\times \frac{7}{12}$. 2. *Muhlenbergia Schreberi* var. *Schreberi*; a. Columbia, south to North Carolina, Ohio, Indiana, Illinois, Missouri, Kansas, New Mexico, Arizona, and California.

Missouri material falls into two categories:

- Lemma without an awn . . . 10a. *M. MEXICANA* f. *MEXICANA*
Lemma with an awn 4–10 mm. long. 10b. *M. MEXICANA* f. *AMBIGUA*

10a. ***Muhlenbergia mexicana* f. *mexicana***

Map 230

The commoner one encountered in Missouri.

10b. ***Muhlenbergia mexicana* f. *ambigua*** (Torr.)
Fern.

Map 230

Infrequent, and known only from Ste. Genevieve, Cape Girardeau, and Howell (gravelly open places along South Fork of Spring Creek along highway A, T23N, R8W, south $\frac{1}{2}$ sect. 33, 8 mi. south of West Plains, Sept. 3, 1949, *Steyermark* 69076) counties.

Muhlenbergia mexicana is most readily distinguished from *M. sylvatica* by the normally awnless lemmas and more densely flowered branches of the inflorescence. Both species have rather bunched and closely branching rhizomes, the scales according to observations of Shinnars (Am. Midl. Nat. 26: 70. 1941) being 2–7 mm. long, whereas in *M. frondosa* they vary from 5–10 mm. long.

11. ***Muhlenbergia Schreberi* Gmel.**

Nimble Will

Map 231

Flowers July–November.

This is found in a wide variety of habitats, ranging from moist low meadows, thickets, open and waste ground, to gravelly banks, wooded sandstone slopes, and pine woods. It is weedy, often found in gardens and about dwellings, and in disturbed or cultivated areas. Throughout Missouri.

Ranges from Florida to Texas and Mexico, north

to New Hampshire, New York, Ontario, Michigan, Wisconsin, Iowa, and Nebraska.

Missouri material falls into two varieties:

- Commonly found; glumes as broad as long, rounded or flat-topped at summit; 2nd glume 0.2–0.5 mm. long; lemma 1.8–2.5 mm. long (excluding awn); awns 2–5 mm. long. 11a. *M. SCHREBERI* var. *SCHREBERI*

Known only from Barry Co.; glumes longer than broad, acute to sharp-pointed at tip; 2nd glume 1–2 mm. long; lemma 2.5–3 mm. long (excluding awn); awn 0.3–2 mm. long. 11b. *M. SCHREBERI* var. *CURTSETOSA*

11a. ***Muhlenbergia Schreberi* var. *Schreberi***

Map 231

Throughout Missouri.

11b. ***Muhlenbergia Schreberi* var. *curtisetosa***

(Scribn.) Steyermark & Kucera Map 231

Muhlenbergia Schreberi curtisetosa Scribn. Rh. 9: 17. 1907.

Muhlenbergia curtisetosa (Scribn.) Bush [G, BB, P & S, Hitchcock]

Known only from Barry County, southwestern Missouri (Eagle Rock, Sept. 24, 1896, *Bush* 377). As suggested by Gleason (*New Ill. Fl.* 1: 174. 1952), *M. curtisetosa* appears to be of doubtful taxonomic status as a species and is placed in the present treatment in the varietal category with *M. Schreberi*, which it closely resembles in general appearance.

Muhlenbergia Schreberi forms dense colonies by virtue of the decumbent to prostrate lower parts of the culm which easily root at the lower nodes and send up slender wiry often purple smooth culms. The roots are fine and slender, and there are no creeping, elongated, scaly underground rhizomes as in most of the other local species. The long-exserted, very narrow panicles are characteristic. The glumes are so small that they might easily be overlooked.

12. **Muhlenbergia capillaris** (Lam.) Trin.

Hair Grass

Map 232

Flowers September–October.

Found in acid soils usually in open woods of deciduous or pine trees, sandstone or more commonly cherty limestone glades, or openings above limestone escarpments, and openings along roads. Occurring only in the Ozark section north to Henry, Pettis, Cooper, and Franklin counties, and locally east to Cape Girardeau County. Absent from the south-eastern lowland section and from many of the eastern Ozark counties.

Ranges from Florida to Texas, north to Massachusetts, Pennsylvania, Kentucky, Illinois, Missouri, and Kansas.

This is a handsome grass with its graceful rosy-purple panicle of hairlike delicate branches and pedicels, and is conspicuous when encountered in the fall. It is a rare grass, however, and not commonly seen. It is characteristic of acid soils and is difficult to transplant and establish in a wild garden.

*Excluded species***Muhlenbergia expansa** (DC.) Trin. Hair Grass

This species was listed by Palmer & Steyermark (1935) in their *Annotated Catalogue* as occurring in McDonald County. This report was based on a misidentified specimen confused with *M. capillaris*.

42. **Sporobolus** R. Br. Dropseed

Chiefly summer- and fall-flowering annual or perennial grasses with awnless spikelets. The fruit, when mature falls readily from the spikelet, and its seed separates easily from the pericarp.

- a. Leaf-sheaths densely bearded at summit 8. *S. CRYPTANDRUS*
- a. Leaf-sheaths glabrous or if pubescent, at least not long-bearded at summit *b*
- b. Inflorescence long and narrow, contracted, spike-like, sometimes enclosed by an inflated sheath; branches of inflorescence erect to ascending close to the main axis *c*
- c. Length of inflorescence $\frac{1}{4}$ – $\frac{1}{2}$ the height (length) of culm (stem); spikelets 1.5–2 mm. long; new stem-leaves 2–3 5. *S. POIRETII*
- c. Length of inflorescence many times shorter than height (length) of culm (stem); spikelets 2–7 mm. long; new stem-leaves 4–12 *d*
- d. At least some part of lemma appressed-pubescent (examine carefully with lens or binocular microscope to note colorless hairs lying flat on surface of lemma) *e*
- e. Inflorescence at very top of stem usually covered over by an inflated leaf-sheath, rarely exserted; inflorescences also arising along the side (axillary) but also covered over by a leaf-sheath; annuals 1. *S. VAGINIFLORUS*
- e. Inflorescence at very top of stem either partly covered over at the base by an inflated leaf-sheath or entirely free and exserted from the leaf-sheath; axillary inflorescence usually absent (rarely 1 or more); perennials 4. *S. CLANDESTINUS*
- d. Lemma wholly glabrous
- f. Glumes nearly equal, the 2nd rarely surpassing the 1st by more than 1 mm.; glumes nearly equaling the lemma in length, 1st glume $\frac{3}{4}$ to as long as length of lemma; inflorescence at very top of stem usually covered over by an inflated leaf-sheath, rarely exserted; inflorescences arising along the side (axillary) but also covered over by a leaf-sheath; annuals 2. *S. NEGLECTUS*
- f. Glumes obviously unequal, the 2nd glume surpassing the first by 1 mm. or more; at least the 1st glume $\frac{1}{3}$ – $\frac{2}{3}$ length of lemma; inflorescence at very top of stem either partly covered over at the base by an inflated leaf-sheath or entirely free and exserted from the leaf-sheath; axillary inflorescence usually absent (rarely 1 or more); perennials 3. *S. ASPER*
- b. Inflorescence open and loose, pyramid-shaped or ovoid, not spike-like; branches of inflorescence spreading to ascending away from main axis *g*
- g. Leaf-blades 2 mm. or less wide; spikelets 4.5–6 mm. long; 1st glume tapering to a long narrow tip 6. *S. HETEROLEPIS*
- g. Leaf-blades 2–5 mm. wide; spikelets 1.5–3.5 mm. long; 1st glume short-pointed (acute) to blunt (obtuse) *h*
- h. Main branches of inflorescence usually alternate; spikelets 1.5–2.5 mm. long 9. *S. AIROIDES*
- h. Main branches of inflorescence opposite or in whorls; spikelets 1.5 mm. long 7. *S. PYRAMIDATUS*

232 *Muhlenbergia capillaris* (Hair Grass)233 • *Sporobolus vaginiflorus* var. *vaginiflorus* (Poverty Grass)
233 □ *Sporobolus vaginiflorus* var. *inaequalis*234 • *Sporobolus neglectus* var. *neglectus* (Poverty Grass)
234 □ *Sporobolus neglectus* var. *ozarkanus*

1. ***Sporobolus vaginiflorus*** (Torr.) Wood
Poverty Grass Map 233
Flowers August–November.

Common on limestone glades, cherty openings in woodland, overgrazed fields and prairies, along railroads, and waste ground, especially sterile soils. Throughout Missouri.

Missouri material falls into two varieties:

Palea and lemma nearly equal in length or only slightly unequal, the glumes nearly as long as palea or longer 1a. *S. VAGINIFLORUS*
var. *VAGINIFLORUS*

Palea conspicuously longer than and prolonged by its slender beak beyond the lemma, the glumes much shorter than the palea 1b. *S. VAGINIFLORUS* var. *INAEQUALIS*

- 1a. ***Sporobolus vaginiflorus* var. *vaginiflorus***
Map 233

Common throughout Missouri.

Ranges from Nova Scotia, Maine, and Quebec, to North Dakota, south to Georgia and Texas.

- 1b. ***Sporobolus vaginiflorus* var. *inaequalis***
Fern. Map 233
Scattered throughout Missouri.

Ranges from Maine to Ontario, south to New York, Pennsylvania, Michigan, Wisconsin, Missouri, Nebraska, and Texas.

There is some intergradation between these two variations with respect to the relative length and prolongation of the apex of the palea. The length of the spikelets is given in some manuals as 3.5–6.5 mm. However, spikelets are sometimes found measuring

only 2.5 mm. long. Such spikelets in Missouri material constitute fully mature, late-season, inflated ones with the surface of the lemma prominently convex. After the fruits have fallen, however, the inflated appearance disappears, and the spikelets become longer and attain 3.5–4 mm. Shinnars (Rh. 56: 29. 1954) also reports finding late-season atypical forms of *S. vaginiflorus* var. *vaginiflorus* with pubescent lemmas of spikelets only 2–2.6 mm. long. The leaf-sheaths are sometimes stated as being glabrous and often long-ciliate at the orifice. Occasionally they are pilose elsewhere on the surface of the sheath.

2. ***Sporobolus neglectus*** Nash Poverty Grass
Map 234

Sometimes called Dropseed or Puffsheath Dropseed *Sporobolus vaginiflorus* var. *neglectus* (Nash) Scribner, erroneously published as a new comb. by Shinnars. Flowers August–November.

Limestone glades, cherty openings in woods, fields, along railroads, and waste ground.

Ranges from New Brunswick, Maine, and Ontario to North Dakota, south to Virginia, Tennessee, Missouri, and Texas.

Missouri material may be placed into two categories:

Spikelets 2–3.5 mm. long; lower leaf-sheaths and blades glabrous or sparsely hairy; grain (seed-like fruit) 1–1.5 mm. long 2a. *S. NEGLECTUS*
var. *NEGLECTUS*

Spikelets 3.5–5 mm. long; lower leaf-sheaths and blades papillose-pilose (hairs with swellings at base); grain (seed-like fruit) 1.7–2.2 mm. long 2b. *S. NEGLECTUS* var. *OZARKANUS*

PLATE NO. 41

237 *Sporobolus Poiretii* (Smut Grass)

2a. *Sporobolus neglectus* var. *neglectus*

Map 234

Common throughout Missouri. Records are absent from parts of southeastern and north central Missouri, although doubtless present.

2b. *Sporobolus neglectus* var. *ozarkanus* (Fern.).

Steyermarck & Kucera

Map 234

Sporobolus ozarkanus Fern. [G, P & S]

Sporobolus vaginiflorus var. *ozarkanus* (Fern.) Shinnery, Rh. 56: 29. 1954.

Occurs in Jasper (barrens, Webb City, September 8, 1910. Palmer 3133, holotype, 3133 A), Lawrence (limestone ledge, open or partly wooded hillside, near Verona, Aug. 22, 1950, Palmer 50816), Ozark (slopes and ledges, bald knobs, 'Bald Jesse,' near Gainesville, Oct. 10, 1927, Palmer 33064) and Barton counties, all in southwestern Missouri.

Plants of this group vary in their amount of pubescence shown on the leaf-sheaths and blades and in the size of their spikelets. Some spikelets of *S. neglectus* var. *neglectus* may attain 3.5 mm. in length (Steyermarck 79874), although the manuals state the length as 2–3 mm. Specimens with conspicuous papillose leaf-sheaths and blades and larger spikelets are placed in var. *ozarkanus*, but intermediates occur, such as Palmer's collection from Barton County. The glabry of the lemmas and their short-pointedness together with the relatively less elongated apex of the palea appear to be characters relating *S. ozarkanus* more closely with *S. neglectus* than with *S. vaginiflorus*, whereas Shinnery judges *S. ozarkanus* as a variety of *S. vaginiflorus*.

The strongly ciliate orifices of the leaf-sheaths, believed by Fernald to be characteristic of *S. ozarkanus*, are also found in *S. vaginiflorus*, and in this respect *S. ozarkanus* resembles *S. vaginiflorus*. However, occasional specimens of *S. neglectus* var. *neglectus* also have ciliate orifices of the leaf-sheath. It is true, also,

that the relatively longer spikelets of *S. ozarkanus* afford another point of resemblance to *S. vaginiflorus*.

On account of the above, it is admitted that *S. ozarkanus* may likely be judged and eventually proved a hybrid, intermediate between *S. vaginiflorus* var. *vaginiflorus* and *S. neglectus* var. *neglectus*.

3. *Sporobolus asper* (Michx.) Kunth Map 235

Flowers August–October.

Common along roadsides and railroads; also occurring in dry prairies and rocky open woods and glades.

Missouri material may be divided into the following varieties:

- a. Inflorescence at tip of culm (terminal inflorescence) relatively thin, loose, linear-filiform, 3–6 mm. thick; spikelets mostly 3–5 mm. long; 1st glume linear-lanceolate 3c. *S. ASPER* var. *HOOKERI*
- a. Inflorescence at tip of culm (terminal inflorescence) relatively dense, stiff, thick-cylindrical, 5–18 mm. thick; spikelets 4.5–6.5 mm. long; 1st glume narrowly ovate b
- b. Leaf-sheaths and blades more or less pilose with conspicuous hairs on all parts 3b. *S. ASPER* var. *PILOSUS*
- b. Usually the upper surface of leaf-blades at the base pilose or hirsute, otherwise rough-scabrous; leaf-sheaths glabrous or the lower ones appressed-pubescent, rarely pilose at the summit 3a. *S. ASPER* var. *ASPER*

3a. *Sporobolus asper* var. *asper* Map 235

Apparently absent in most of the eastern portion of the Ozarks and the southeastern quarter section of the state, otherwise common in the remainder of Missouri.

Ranges from Quebec, Vermont, New York, and Ohio to North Dakota, south to Virginia, Tennessee, Louisiana, and Texas.

3b. **Sporobolus asper** var. **pilosus** (Vasey)
Hitchc. Map 235
Scattered in a few counties of the Ozark section of the state.

Ranges from Missouri and Kansas to Texas.
This is included by Shinnars (Rh. 56: 29. 1954) under *S. asper* var. *Hookeri*, but I am maintaining it as the pilose-leaved variation of plants with the dense thick-cylindrical inflorescences more characteristic of *S. asper* var. *asper*.

3c. **Sporobolus asper** var. **Hookeri** (Trin.)
Vasey Map 235
Sporobolus Drummondii (Trin.) Vasey [G]
Usually found on glades, prairies, and rocky open woods over much the same range as *S. asper* var. *asper*, but less common north of the Missouri River. Absent from most of the eastern quarter of the state.

Ranges from Missouri to Mississippi and Texas.
Overlapping of measurements of the length of the spikelets breaks down distinctions between *S. asper* var. *asper* and the other varieties. There is also intergradation in the width of the 1st glume. For example, *Palmer 60937* from McDonald County has the slender inflorescence of *S. asper* var. *Hookeri* with spikelets 4-5 mm. long, but the 1st glume is not as narrow as in *S. asper* var. *Hookeri*.

Sporobolus asper var. *asper* and other varieties are drought-resistant bunch grasses. They spread into overgrazed areas where bluestem (*Andropogon scoparius*) is prevalent. The stems and long leaves of *S. asper* var. *asper* turn whitish during the winter. Often called 'flag grass' on account of the habit of the upper leaves waving in the wind which is especially noticeable on cutover prairies in the autumn.

4. **Sporobolus clandestinus** (Biehler) Hitchc.
Map 236
Flowers August-October.
Missouri material falls into two categories:

Palea much prolonged beyond the lemma into a narrowed nearly awned beak; spikelets 5.5-8 mm. long . . . 4a. *S. CLANDESTINUS* var. *CLANDESTINUS*
Palea and lemma nearly equal, the palea not prolonged into a nearly awned beak; spikelets 4.5-6 mm. long. 4b. *S. CLANDESTINUS* var. *CANOVIRENS*

4a. **Sporobolus clandestinus** var. **clandestinus**
Map 236
Sporobolus clandestinus (Biehler) Hitchc. [G]
Sporobolus asper var. *clandestinus* (Biehler) Shinnars, Rh. 56: 30. 1954.
Rocky open woods, glades, edges of bluffs, and

prairies. Scattered in several counties of the Ozark section.
Ranges from Connecticut, Indiana, and Missouri to Florida and Texas.

4b. **Sporobolus clandestinus** var. **canovirens**
(Nash) Steyermark & Kucera Map 236
Sporobolus canovirens Nash [G]
Sporobolus asper var. *canovirens* (Nash) Shinnars, Rh. 56: 30. 1954.
Rocky open woods, glades, edges of bluffs, and prairies. Much commoner than *S. clandestinus* var. *clandestinus*, throughout the Ozark region north to Henry, Boone, Montgomery, and Lincoln counties, and locally in Clark County, northeast Missouri.
Ranges from Indiana and Wisconsin to Kansas, south to Mississippi and Texas.

There is intergradation between the two variations of *S. clandestinus* in spikelet length, in the relative length between palea and lemma, and in the degree of prolongation of the palea. Extremes of the two types are found which appear very distinct, but since transitions are often difficult to place, their reduction to varietal rank appears more consistent.
As both variations possess consistently pubescent lemmas, characteristic of *S. clandestinus*, it is believed that they should be kept separate as distinct varieties of that species, rather than merged, as Shinnars has done, as varieties of *S. asper*, the latter species, together with its varieties, possessing glabrous lemmas.

5. **Sporobolus Poiretii** (R & S) Hitchc.
Smut Grass Map 237
Flowers May-October.
Known only from southeastern Missouri in Dunklin County (Oct. 26, 1892, *Bush*), where introduced in cotton fields.

This species is reported from dry sandy or wet open soil, roadsides, and along ditches, from Florida to Texas, north to Virginia, Kentucky, and southeastern Missouri. Also native throughout tropical America and tropical Asia, and adventive in New Jersey.

No specimen has been found in the state since the original collection by Bush. It is probable that the species is now extinct in Missouri.
The common name for this grass is due to a black fungus, which frequently infects the inflorescence.

6. **Sporobolus heterolepis** Gray
Prairie Dropseed Map 238
Flowers August-October.
Prairies, glades, rocky cliffs, and open ground along railroads. Throughout Missouri, except absent

238 *Sporobolus heterolepis* (Prairie Dropseed)239 *Sporobolus pyramidatus*240 *Sporobolus cryptandrus* var. *cryptandrus* (Sand Dropseed)

in the southeastern lowland region, and extreme northwestern Missouri.

Ranges from Quebec to Saskatchewan, locally south to New York, Ohio, Indiana, Illinois, Arkansas, Texas and Wyoming; local eastward from Connecticut to Pennsylvania.

This grass forms conspicuous large clumps of handsome narrow, almost hairlike, long blades, which are mostly basal and curl or arch gracefully backwards. The long-exserted openly branched panicles are purple to blackish.

7. ***Sporobolus pyramidatus*** (Lam.) Hitchc.

Map 239

Sporobolus argutus (Nees) Kunth [P & S]

Flowers May–October.

Known only from dry open ground where introduced in Jackson County (Westminister, July 27, 1896, *Bush 510*).

Ranges from Kansas and Colorado to Louisiana and Texas, south to the West Indies, Mexico to Nicaragua, and South America. Introduced eastward in Missouri and New York.

Not collected in the state since Bush's original collection.

8. ***Sporobolus cryptandrus*** (Torr.) A. Gray var. ***cryptandrus*** Sand Dropseed

Map 240

Flowers July–October.

Usually found on dry sandy flats bordering the Missouri and Mississippi rivers, also on loess mounds of northwestern Missouri, and infrequently on exposed

limestone strata; also introduced along railroads.

Absent from most parts of Missouri. Confined to those habitats indicated above, which limit the geographic range to northwestern, central, and extreme eastern Missouri south of the Missouri River. Apparently absent from most of northern Missouri, and locally south in Texas and Jasper counties.

Ranges from Quebec to Washington, south to North Carolina, Ohio, Indiana, Illinois, Louisiana, Texas, and Mexico.

This is so characteristic of sandy areas that one can almost be certain of encountering it in any area where there is pure sand. It is probable that this species will be found eventually in all the counties along the Mississippi and Missouri rivers in the state where sand bars exist.

It is reported that the Kiowa Indians employ the seeds of this species for a flour which is obtained by grinding the dried grains. It is believed that other species of this genus *Sporobolus* can be similarly employed for production of a flour.

9. ***Sporobolus airoides*** Torr. Alkali Sacaton,
Fine top Salt Grass

Map 241

Flowers May–October.

Loess hills in Atchison County, northwestern Missouri, and introduced in Jackson County (common, Sheffield, June 12, 1895, *Bush 788*).

Ranges from South Dakota to Washington, south to Missouri, Kansas, Texas, and Mexico, usually growing on alkaline flats, prairies, and sands; introduced eastward in New York.

Plate no. 42. 1. *Sporobolus cryptandrus*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{7}{12}$; c. Glumes, $\times \frac{7}{12}$. 2. *Sporobolus Poiretii*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{7}{12}$; c. Spikelet, $\times \frac{7}{12}$. 3. *Sporobolus pyramidatus*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c. Glumes, $\times \frac{7}{12}$. 4. *Sporobolus heterolepis*; a. Plant, $\times \frac{3}{4}$; b. Floret with caryopsis and split palea, $\times \frac{7}{12}$; c. Spikelet, $\times \frac{7}{12}$.

PLATE NO. 42

241 *Sporobolus airoides* (Fine Top Salt Grass)242 *Heleochloa schoenoides*243 *Brachyelytrum erectum* var. *erectum*43. *Heleochloa* Host

Low annual grasses with short leaf-blades and dense short spike-like inflorescences. Ligule a zone of hairs.

Heleochloa schoenoides (L.) Host Map 242
Flowers July–September.

Fields, meadows, along railroads, and waste places in St. Louis (streets of St. Louis, 1878, and 1881, Eggert; along railroads, *Muehlenbach*) and Franklin

(meadows, Gray Summit, July 9, 1926, *Kellogg 15033*), counties.

Native of Europe; introduced into the United States, ranging from Massachusetts to Wisconsin, south to Delaware, Pennsylvania, Iowa, and Missouri.

44. *Brachyelytrum* Beauv.

Perennials with several slender, erect stems in a clump. Leaves flat, elongated and rather broad and spreading. Ligule truncate-erose, membranous. Inflorescence a narrow, loosely-flowered panicle.

Brachyelytrum erectum (Schreb.) Beauv.
var. *erectum* Map 243
Flowers June–August.

Common in woodland, especially on rich or rocky steep slopes. Throughout Missouri, except in a few southeastern lowland counties.

Ranges from Massachusetts to Wisconsin and Iowa, south to Georgia, Alabama, Mississippi, and Louisiana. A more northern variety (var. *septentrionale* Babel) with glabrous or very short puberulent lemmas

extends south to Minnesota and Ohio.

The spikelets fall easily and do not remain attached for long to the rachis after reaching maturity. The leaf-blades are 2-ranked, spreading out in two opposite directions.

In its vegetative appearance this grass resembles *Uniola latifolia*, but may be easily distinguished by the minutely hairy leaf-sheaths with downward-pointing (retorse) pubescence, the narrower leaf-blades, and more slender, shorter culms (stems).

45. *Oryzopsis* Michx. Mountain Rice, Rice Grass

Tufted perennial grasses. Our local species have a loosely-flowered simple panicle with ascending branches. The lemma is thickened and hardened.

Oryzopsis racemosa (Sm.) Ricker
Black-seeded Mountain Rice Map 244
Flowers late May–early September.

Wooded slopes, eastern Missouri, where known from Clark (common, Aug. 26, 1892, *Bush*) and Shannon (July 2, 1886, *Tracy*) counties.

This species is a northern relict, reaching its south-

western limit of geographical distribution in Missouri.

Ranges from Maine and Quebec to North Dakota, south to Delaware, Virginia, Kentucky, and Missouri.

The large seeds of one of the species in this genus, *O. asperifolia*, are reported to contain a starchy content desirable for making into a flour.

PLATE NO. 43

244 *Oryzopsis racemosa* (Black-seeded Mountain Rice)245 *Stipa spartea* (Porcupine Grass)246 *Aristida basiramea* (Triple Awn Grass)

46. *Stipa* L. Porcupine Grass

Rather tall perennial grasses growing (our local species) in small tufts. Leaf-blades narrow and elongated. Panicles narrow (in the local species).

***Stipa spartea* Trin.** Porcupine Grass Map 245
Flowers May-June.

Dry or rocky prairies, roadsides, and along railroads. Rather frequent in the glaciated and unglaciated prairie region of northern and western Missouri east to Schuyler, Shelby, Moniteau, Morgan, Benton, Cedar, and Lawrence counties. Absent from the Ozark and southeastern lowland region.

Ranges from Ontario to British Columbia, south to Pennsylvania, Ohio, Indiana, Illinois, Missouri, Kansas, and New Mexico.

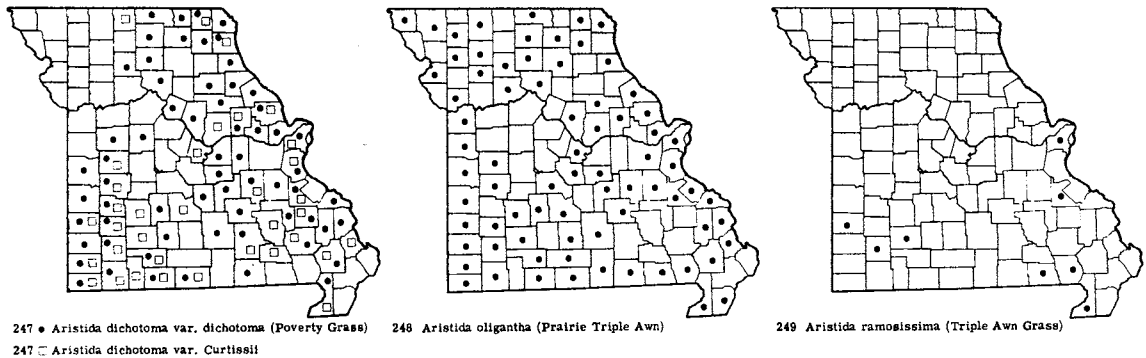

Although the grass is highly nutritious and palatable to all livestock in its vegetative stage of growth from September to April, it can injure grazing animals during the period of seed formation (May-August) with the long-pointed awns. These get caught in the tender mouthparts, causing mechanical injury to the tissues.

The automatic twisting and untwisting of the awn as a response to change in atmospheric moisture enables the sharp-pointed seed to become buried in the soil with subsequent germination.

47. *Aristida* L. Triple-awned Grass, Three-awn Grass

Annual or perennial grasses, usually flowering in late summer and autumn. Leaves very narrow, often with inrolled margins and minute ciliate ligules. The glumes and lemma are narrow, the lemma ending in 3 awns, which are either separate to their base or united into a short column; sometimes the lateral ones are greatly reduced in size or lacking.

- a. Lower and young leaf-sheaths with woolly or cobwebby gray-white hairs; at least lower nodes of inflorescence with tufts of wool 8. *A. LANOSA*
- a. Leaf-sheaths not woolly; nodes of inflorescence without tufts of wool *b*
- b. At least 1 of the 3 awns of a floret 20-70 mm. long *c*
- c. Glumes 6-10 mm. long; awns ascending 7. *A. INTERMEDIA*
- c. The longer of the two glumes 8-30 mm. long; awns horizontally spreading or reflexed. *d*
- d. First glume 12-30 mm. long, 3-5-nerved; annuals with soft bases; leaf-sheaths never hairy with long hairs 3. *A. OLIGANTHA*
- d. First glume 8-14 mm. long, 1-nerved; perennials with firm hard bases; leaf-sheaths often hairy with long hairs 9. *A. PURPURASCENS*
- b. Some of the 3 awns of a floret less than 18 mm. long. *e*
- e. The longer of the two glumes 8-30 mm. long *f*
- f. None of the awns coiled at the base; perennials with firm or hard bases; leaf-sheaths often hairy with long hairs 9. *A. PURPURASCENS*
- f. One of the awns of each floret coiled at base; annuals with soft bases; leaf-sheaths never hairy with long hairs *g*
- g. Lateral awns of lemma 1-6 mm. long; the longer (upper) of the two glumes 15-28 mm. long; glumes 2-5-nerved 4. *A. RAMOSISSIMA*

- g. Lateral awns of lemma 5–10 mm. long; the longer (upper) of the two glumes 9–15 mm. long; glumes 1-nerved 1. *A. BASIRAMEA*
- e. The longer of the two glumes 5–12.5 mm. long h
- h. One of the awns of each floret coiled at base 2. *A. DICHOTOMA*
- h. None of the awns coiled at the base i
- i. One of the awns of each floret abruptly bent and much longer than the other 2 shorter lateral awns 5. *A. LONGESPICA*
- i. All 3 awns of each floret about equal in length and equally ascending j
- j. Awns 15–24 mm. long; awns terete (circular in cross-section); hardened part (callus) at base of lemma acute (sharp pointed), sparsely bearded; glumes nearly equal or the 1st about 4/5 length of the 2nd 7. *A. INTERMEDIA*
- j. Awns 8–15 mm. long; awns flat at base; hardened part (callus) at base of lemma obtuse (blunt), densely bearded; glumes unequal, the 1st 1/2–2/3 length of the 2nd. 6. *A. ADSCENSIONIS*

1. ***Aristida basiramea*** Engelm. Map 246
Flowers August–October.
Dry open ground. Scattered in southern and central Missouri.
Ranges from Michigan to North Dakota, south to Illinois, Missouri, and Kansas. Introduced from Maine to New York.

2. ***Aristida dichotoma*** Michx. Poverty Grass Map 247
Flowers August–October.
Occurs in rocky prairies, glades, open upland woods, eroded slopes, waste ground, and roadsides. Often found in hard, white clay soil, and hard baked ground along roads.

Missouri material falls into two variations:
Lemmas 5–7 mm. long; glumes nearly equal, 6–9 mm. long, the 1st usually longer than the lemma; longer central awn usually 3–7 mm. long
2a. *A. DICHOTOMA* var. *DICHOTOMA*
Lemmas 7–10 mm. long; glumes conspicuously unequal, the 2nd 8–12.5 mm. long, the 1st 1/2–3/4 as long, the 1st usually shorter than the lemma; longer central awn 6–12.5 mm. long
2b. *A. DICHOTOMA* var. *CURTISSII*

2a. ***Aristida dichotoma*** var. ***dichotoma*** Map 247
Aristida dichotoma Michx. [G, BB, P & S]
Southern, central, and eastern Missouri, north of the Missouri River extending west to Putnam, Sullivan, Livingston, and Chariton counties.
Ranges from Florida to Texas, north to Maine, New York, Ohio, Michigan, Illinois, Missouri, and Kansas.

Some Missouri specimens attain a height of 8 dm., although 6 dm. is given as the tallest height in *Gray's Manual*, eighth edition. The usual height is 2–4 dm.

2b. ***Aristida dichotoma*** var. ***Curtissii*** Gray Map 247
Aristida Curtissii (Gray) Nash [BB, P & S]
Aristida basiramea var. *Curtissii* (Gray) Shinnars [Fassett]
Similar range to that of *A. dichotoma* var. *dichotoma*, but less common.
Aristida dichotoma var. *dichotoma* and var. *Curtissii*, along with other species of the genus cause mechanical injuries to the mouthparts of grazing animals when eaten in the mature state.

250 • *Aristida longespica* var. *longespica* (Poverty Grass)
250 □ *Aristida longespica* var. *geniculata*

251 *Aristida adscensionis* (Triple Awn Grass)

252 *Aristida intermedia* (Triple Awn Grass)

3. *Aristida oligantha* Michx.

Prairie Three Awn Grass

Map 248

Rocky glades, fallow dry fields, eroded slopes, clayey roadsides, open waste ground, and along railroads. Hard, white, clay soil is a frequent habitat for this and other species of the genus.

Common throughout Missouri; this is the most frequently encountered species of *Aristida* in the state.

Ranges from Florida to Texas, north to New York, Pennsylvania, Ohio, Michigan, Wisconsin, Iowa, and South Dakota; also in California and Oregon; introduced in Massachusetts.

The lengths of the awns of this grass are stated in some of the manuals to vary from 3.5–7 cm., but some Missouri specimens have awns only 2–3 cm. long.

This grass commonly grows in overgrazed areas and places where it has no competition with other plants, such as on thin, eroded, and rocky soils. When mature this species assumes a whitish color, and becomes tough and wiry. In the mature stage its awns are responsible for mechanical injuries to grazing animals.

4. *Aristida ramosissima* Engelm.

Map 249

Flowers July–October.

Dry prairies, glades, and sterile or open clayey soils. Scattered in southern and east-central Missouri north to St. Louis County. This is a rare annual species in the state, known only from a few stations.

Ranges from Indiana to Iowa, south to Tennessee, Louisiana, and Texas.

5. *Aristida longespica* Poir. Poverty Grass

Map 250

Flowers August–October.

Rocky prairies, glades, edges of bluffs, fallow sterile fields, open woods, eroded slopes, open and waste

ground, especially in hard clayey soil, and along roadsides and railroads. Scattered throughout the state, except not recorded from the northwestern sector.

Missouri material falls into two variations:

Second glume 5–6 mm. long; central awn 5–13 mm. long; lateral awns 1–4 mm. long. . . .

5a. *A. LONGESPICA* var. *LONGESPICA*

Second glume 5–9 mm. long; central awn 10–21 mm. long; lateral awns 4–15 mm. long. . . .

5b. *A. LONGESPICA* var. *GENICULATA*

5a. *Aristida longespica* var. *longespica* Map 250

Aristida longespica Poir. [G, P & S]

The common variety in Missouri.

Ranges from Florida to Texas, north to Connecticut, Ohio, Michigan, Illinois, Missouri, and Kansas.

5b. *Aristida longespica* var. *geniculata* (Raf.)

Fern.

Map 250

Aristida intermedia according to Shinners in Rh. 56: 30. 1954, not Scribn. & Ball

Rare in southern and central Missouri, north to Morgan and Moniteau counties.

Ranges from Florida to Texas, north to New Hampshire, Vermont, New York, Ohio, Indiana, and Missouri.

6. *Aristida adscensionis* L.

Map 251

Flowers July–October.

Upland prairies, wooded sandstone slopes, and sterile open ground. Rare in western Missouri, where known from a few stations south of the Missouri river north to Jackson County. Material from Maries and Madison counties in eastern Missouri, previously referred to this species, was based upon misdetermined specimens.

PLATE NO. 44

253 *Aristida lanosa* (Triple Awn Grass)254 *Aristida purpurascens* (Triple Awn Grass)255 a *Leptochloa filiformis* var. *filiformis*
255 □ *Leptochloa filiformis* var. *attenuata*

Ranges from Missouri, Kansas, and Colorado to Texas and California, south to Mexico, Guatemala, South America, and the West Indies; also in warmer parts of Asia and Africa.

7. ***Aristida intermedia*** Scribn. & Ball Map 252
Aristida longespica var. *geniculata* of Shinnery in Rh. 56: 30. 1954, not (Raf.) Fern.
Aristida necopina Shinnery
 Flowers July–October.

Glades, rocky dry open woods, upland prairies, and sandy open ground. Scattered in a few parts of southern and central Missouri.

Ranges from Indiana, Michigan, Wisconsin, and Nebraska, south to Mississippi and Texas.

According to Shinnery, much of the material previously passing as *A. intermedia* of most authors, not Scribner & Ball, is *A. necopina* Shinnery, while true *A. intermedia* Scribn. & Ball, according to him, is *A. longespica* var. *geniculata* (Raf.) Fern.

8. ***Aristida lanosa*** Muhl. Map 253
 Flowers September–November.

Known only from sandy open wooded slopes and ridges, and sandy open soil in valley openings on Crowley Ridge, southeastern Missouri, in Dunklin (east-facing slopes, Crowley Ridge, T23N, R9E, sect. 26, 6½–7 mi. northwest of Malden, October 30, 1956, *Steyermark* 83363) and in Stoddard (sandy openings in valley, Crowley Ridge, on property of Mr. Martin, T25N, R11E, northwest ¼ sect. 6, 3¼–3¾ mi. southeast of Bloomfield, August 20, 1954, *Steyermark* 76744; T25N, R10E, northeast ¼ sect. 1, on property of Mr. Kidd, 3¼–3¾ mi. southeast of Bloomfield, October 18, 1955, *Steyermark* 80387; sandy prairie in valley on east side of road and gully, Crowley Ridge, T26N,

R10E, sect. 31, 3¼ mi. southeast of Bloomfield, October 17, 1955, *Steyermark* 80332, 80342, 80343, 80356; *Bush* without locality) counties.

Ranges from Florida to Texas, north to New Jersey, West Virginia, and southeast Missouri.

This very distinct perennial woolly species of *Aristida* was originally known in Missouri by a collection of *Bush* labeled 'Stoddard County,' without any specific locality data. The grass was not relocated again until the author's collections in 1954–56, when it was found to be of rather frequent occurrence on open sandy dunes on the ridges and in sandy valleys of Crowley Ridge.

9. ***Aristida purpurascens*** Poir. Map 254
Aristida purpurascens var. *minor* Vasey [G]
 Flowers August–October.

Occurs most frequently in dry open oak or pine-oak woodland developed over acid rock strata of chert, sandstone, or granite; sometimes found on sandstone, chert, and granite glades, and in open sterile ground. Found only in the Ozark region of southern and central Missouri, north to Lincoln, Montgomery, Osage, Moniteau, Pettis, Henry, and Vernon counties.

Ranges from Massachusetts to Michigan, Wisconsin, and Kansas, south to Florida and Texas, and British Honduras, Central America.

Aristida purpurascens var. *minor* is distinguished by some authors by the relatively thinner panicles, and smaller first glume 6.5–9 mm. long. It does not appear to have particular taxonomic significance, however, and is not maintained in the present treatment.

This perennial species is frequently encountered throughout the Ozark region on acid soil in oak-hickory or oak-pine woods, frequently with sour gum and red maple. The leaves are grayish-green in small

PLATE NO. 45

bunches, sometimes curled at the base of the plant, as in *Danthonia spicata*. The inflorescences are somewhat purplish, accounting for the specific scientific name of the plant.

The lower leaf-sheaths vary from glabrous or sparsely hairy to rather conspicuously villous. The nearly equal awns vary from spreading to ascending, and from 1.2–3 cm. long.

Tribe VI. CHLORIDEAE

The grasses of this tribe may have the spikelets 1-flowered, or 2–3-flowered. The spikelets are usually arranged in 2 rows, these usually appearing along one side of the rachis, forming simple 1-sided spikes, racemes, or are digitately branched. Articulation of the spikelets is usually above the glumes, but is below the glumes in *Spartina* and *Beckmannia*.

48. *Leptochloa* Beauv. Feathergrass, Sprangle Top

Annuals with elongated panicles having a feather-like or simple pinnate branching, the numerous very narrow branches with 2–4-flowered spikelets, the uppermost floret of each spikelet usually imperfect or barely developed; spikelets arranged in 2 rows along one side of the slender rachis.

The genus is maintained here in the sense used by Fernald in the eighth edition of *Gray's Manual*, consisting of the following taxa.

Leptochloa filiformis (Lam.) Beauv.

Red Sprangle Top

Map 255

Flowers July–October.

Frequents alluvial banks, mud flats, flood plains and valleys of the larger rivers (Missouri and Mississippi) and tributaries, and moist ground of cultivated fields in valleys along streams, mainly in eastern and central Missouri.

Missouri material falls into the following categories:

Glumes merely pointed at tip, the tip not drawn out into a little awn; lemmas 1–1.3 mm. long, minutely hairy on midrib on lower margin; 2nd glume shorter than or rarely longer than the upper floret of the spikelet. . . .

1a. *L. FILIFORMIS*
var. *FILIFORMIS*

Glumes aristate, the tips with little awns; lemmas 0.5–1 mm. long, mainly glabrous or with only a few inconspicuous hairs; 2nd glume usually longer than upper floret of the spikelet. . . .

1b. *L. FILIFORMIS* var. *ATTENUATA*

1a. *Leptochloa filiformis* var. *filiformis*

Map 255

Ranges from Florida to Texas and New Mexico, north to Virginia, Indiana, Illinois, Missouri, and Kansas; introduced in Massachusetts. Native also in Mexico, Central America, the West Indies, and South America.

1b. *Leptochloa filiformis* var. *attenuata* (Nutt.)

Steiermark & Kucera

Map 255

Leptochloa attenuata (Nutt.) Steud. [G, BB];

Ranges from Illinois to Louisiana and Texas.

The two variations of *Leptochloa filiformis* are quite distinct in extreme specimens. However, many intergradations are found among specimens in Missouri with both types sometimes appearing together. In general, *L. filiformis* var. *filiformis* is taller, attaining 1.2 meters in height, and the inflorescence is often larger with 20–100 stiff spikes (branches) to an inflorescence, while *L. filiformis* var. *attenuata* is usually shorter in stature, and the inflorescence is usually smaller with only 10–30 flexuous spikes to an inflorescence. Unfortunately, tall-growing plants (characteristic of *L. filiformis* var. *filiformis*) are found with aristate glumes and smaller lemmas of *L. filiformis* var. *attenuata*, while low-growing plants (characteristic of *L. filiformis* var. *attenuata*) occur with the acute glumes and larger lemmas of *L. filiformis* var. *filiformis*. The same lack of correlation is noted occasionally between the greater or lesser length of the glumes with respect to the upper floret and the height of the plant.

Deam (*Grasses of Indiana*, p. 198. 1929) also had difficulty in determining whether a specimen placed by him in *Leptochloa attenuata* should warrant specific or varietal status.

256 *Eleusine indica* (Goose Grass)257 *Cynodon Dactylon* (Bermuda Grass)258 *Schedonnardus paniculatus* (Tumble Grass)

Eleusine indica (L.) Gaertn.

Map 256

Flowers July–October.

Frequents cultivated and waste ground, lawns, gardens, pastures, and along roadsides and railroad tracks. Throughout Missouri.

Native of the Old World; introduced into the United States, ranging from Quebec to Minnesota and South Dakota, south to the Gulf States and west

to the Pacific Coast.

Abnormal forms are sometimes found, in which some or all of the spikelets of an inflorescence have changed into leafy or vegetative shoots (*Muehlenbachs* 1487 from St. Louis Co.).

The seeds are said to be ground as a flour for bread or soup in times of emergency by Arabs and various nomadic peoples in Africa.

Cynodon Dactylon (L.) Pers.

Bermuda Grass

Map 257

Flowers June–October.

Most abundant in sandy soils in southeastern and southwestern Missouri; scattered elsewhere in southern and central Missouri north to St. Charles, Boone, and Jackson counties, in open, sandy, waste, cultivated ground, along roadsides and railroad tracks.

Native of Europe; introduced into the southern United States, ranging north to New Hampshire, New York, Ohio, Michigan, northern Illinois, Iowa, Missouri, and Kansas.

Certain strains (Ormond and Tifton 57) are recommended as the best strains for lawn grasses in the southern states; other strains of Bermuda grass are

used for golf greens and areas of fine turf. For best growth Bermuda grass should have full sun, slightly acid to neutral soil, regularly applied fertilizer, and close mowing.

It is not known how far north in the state Bermuda grass will succeed as a permanent lawn grass, but probably would succeed in the northern sections of the state. The grass seldom perfects seed, maintaining itself vegetatively by creeping underground rootstocks or stolons.

Because of its long flowering season, wide geographical distribution, and very light and prolific pollen, Bermuda grass is considered to be the worst hay fever grass in the United States.

51. **Schedonnardus** Steud.

Low-growing tufted annuals with short narrow leaves and a large open inflorescence from half to more than half the entire height of the plant with rather widely-spaced slender branches (spikes). The 1-flowered spikelets are sessile and tightly pressed in 2 rows along side of the slender axis (rachis). The ligule is membranous.

PLATE NO. 46

259 *Beckmannia syzigachne*260 *Spartina pectinata* (Slough Grass)261 *Gynopogon ambiguus* (Beard Grass)**Schedonnardus paniculatus** (Nutt.) Trel.

Tumble Grass

Map 258

Flowers May–October.

Occurs on prairies, calcareous exposed hills and mounds, glades, open fields, waste ground, and, rarely in dry open woods. Western half of Missouri east to Mercer, Boone, Laclede, and Wright counties.

Ranges from Saskatchewan to Montana, south to

Illinois, Missouri, Texas, New Mexico, and Arizona; also in Argentina.

After flowering, the entire inflorescence lengthens and curves, eventually breaking from the plant at maturity to be blown away as a tumbleweed. It invades native grass ranges in the western states often as a result of overgrazing.

52. Beckmannia Host.

Tall erect annual grasses; the flat moderately broad leaf-blades with a large ligule. Inflorescence with numerous short, crowded, upright to ascending spikes in a long and narrow panicle. The glumes are cross-wrinkled.

Beckmannia syzigachne (Steud.) Fern.

(scissorslike glumes)

Map 259

Flowers June–August.

Wet open ground, introduced in Jackson County, western Missouri. A collection by Engelmann (swampy ground on [Massey or Murrey?] Creek, July 17, 1859) exists in the Missouri Botanical Garden Herbarium, but it is not known whether this locality is on the Illinois or Missouri side of the Mississippi River in the vicinity of St. Louis.

Ranges from Quebec to Alaska, south to Michigan, northeastern Illinois, northwestern Iowa, Kansas,

New Mexico, and California; introduced eastward to New York, Pennsylvania, and Ohio, and south to Missouri. Also found in Asia.

This grass, where native, is suitable as a forage grass, and sometimes cut for hay. The seeds were gathered and parched by the Indians for food.

Sometimes called 'Slough Grass' or 'American Slough Grass,' but it should not be confused with the better-known and more widespread *Spartina pectinata*, which is often known, at least in Missouri, by the name 'Slough Grass,' here applied to *Spartina* in the present treatment.

53. Spartina Schreb. Cord Grass, Slough Grass

Perennial plants, usually forming colonies, with long underground rhizomes, long narrow leaves; and 1-flowered flattened spikelets closely overlapping in 2 rows on 1 side of the branch (rachis), the branches (spikes) usually 5–30.

Spartina pectinata Link Slough Grass,

Prairie Cord Grass

Map 260

Spartina pectinata var. *Suttiei* (Farw.) Fern. [G, P & S]

Flowers late June–September.

Frequents low meadows and swampy open ground of valleys and river bottom soils, margins of sloughs and ponds, wet and dry prairies, along railroads, and

along roadsides in low ground. Common in all parts of northern and central Missouri, and along the western sectors, becoming infrequent to scarce in the southeastern and southern portions of the state. Apparently absent from a number of counties in the Ozarks and southeastern lowlands.

Ranges from Newfoundland to Alberta and Washington, south to North Carolina, West Virginia, Indiana, Illinois, Kentucky, Missouri, Arkansas, Texas, New Mexico, and Oregon. Introduced into Europe.

Spartina pectinata var. *Suttiei* has been separated on the basis of narrower, longer spikes (branches), 3–5 mm. wide (instead of 5–8 mm.), with appressed instead of salient awns of the spikelets. However, while selected examples and extremes exhibit these differences, there is a conspicuous absence of correlation in these characters. The most recent monographer of *Spartina*, Dr. David G. Mobberley, has concluded, likewise, that the var. *Suttiei* cannot be maintained as a variety (Iowa State College Jour. Sci. 30: 553–58. 1956), and that those who previously recognized it as distinct were 'dealing with selected extremes of a somewhat

variable population rather than with discrete infraspecific taxa.'

Although Dr. Mobberley states (*loc. cit.* p. 560) that for this grass 'the primary habitat seems to be open dry prairie or high ground along railroad right-of-way and roadsides, in many sections of Missouri where I have observed it, *Spartina pectinata* is mostly found in low wet swales, bottom prairies, and low wet ground. It often forms extensive colonies in the wet bottom prairies of the Grand, Chariton, and other large rivers of northern and central Missouri. The razor-sharp rough edges of the leaf-blades can easily cut the skin of tender, unwary hands that suddenly grasp or otherwise handle them without caution.

If cut while still young and tender, this grass makes a fairly good hay. Ordinarily, the grass is cut 2 or 3 times a year to produce more yield and hay crops. The marsh hay of the Atlantic Coast, often used for purposes of packing or for bedding, is usually obtained from *S. patens*. *Spartina pectinata* was used by the early pioneers and Indians for thatching roofs and for covering haystacks and corncribs. This is not considered to be an important grass in causing hay fever.

54. *Gymnopogon* Beauv. Beard Grass

Perennials (in the local species) with rather stiffly spreading leaves, a minute ligule, and numerous, slender, widely spreading or reflexed branches (spikes).

Gymnopogon ambiguus (Michx.) BSP.

Beard Grass

Map 261

Flowers July–September.

Frequents pine or oak-hickory open woodland in acid soils overlying sandstone or chert, either on dry rocky slopes or in flat sandy valley soils; also in sandy open places and glades, where limited to the Ozark

sector of southern and east-central Missouri north to Barton, Polk, Phelps, Crawford, and St. Charles counties.

Ranges from Florida to Texas, north to New Jersey, Ohio, Indiana, Missouri, and Kansas.

An attractive grass with leaves resembling some species of *Panicum*.

55. *Chloris* Sw. Windmill Grass

Annual or perennial grasses with digitate branches (spikes) arising from the summit of the culm. The spikelets have 1 perfect flower and 1 or more empty lemmas, and are sessile in 2 rows along the triangular-sided rachis.

Some part (fertile lemma) of each spikelet prominently white-hairy on the margin at the summit, giving the whole spikes a feathery appearance; spikelets closely overlapping each other (imbricate). . . . 1. *C. VIRGATA*

No part of the spikelet more than inconspicuously covered with hairs pressed along the surface of the fertile lemma, the spikelets not presenting a feathery or hairy appearance; spikelets not overlapping each other 2. *C. VERTICILLATA*

1. *Chloris virgata* Sw. Feather Finger Grass

Map 262

Flowers July–October.

Occurs in fields and along railroads. Known only from St. Louis (Baden freight yard [Mo.-Kan.-Tex. R. R.] north of the junction with Terminal Railroad

PLATE NO. 47

262 *Chloris virgata* (Feather Finger Grass)263 *Chloris verticillata* (Windmill Grass)264 *Bouteloua curtipendula* (Side Oats Grass)

Association, St. Louis, July 8, 1956, *Muehlenbach 1002*) and Jackson (fields, Courtney, October 13, 1921, *Bush 9733*; introduced, Courtney, September 5, 1913, *Bush 7005*) counties.

Introduced in Maine, Massachusetts, New York, North and South Carolina, and Missouri; ranging from Nebraska to Nevada, south to Texas and California, Mexico, Central America (Guatemala), West Indies, and South America.

An annual grass which is weedy in the southwestern United States. It affords forage in those sections of the Southwest where abundant.

2. ***Chloris verticillata*** Nutt. Windmill Grass

Map 263

Flowers May–October.

Upland dry prairies, lawns, waste ground, and along railroad tracks, where scattered in parts of central and southern Missouri, but absent from the southeastern quarter; extends north to St. Louis, Boone, and Clay counties.

Ranges from Nebraska and western Missouri to Colorado, south to Louisiana and New Mexico; introduced eastward in parts of Missouri, Iowa, Illinois, Indiana, and Maryland.

When mature the entire inflorescence breaks off and is blown around like a tumbleweed. This is a perennial grass which forms clumps by rooting at the lower nodes. It invades overgrazed ranges in the southwestern states.

56. ***Bouteloua*** Lag. Grama Grass

Perennial (in local species) grasses usually in clumps. The 1 to many short spikes (branches), racemously arranged, bear crowded, sessile spikelets in 2 rows on 1 side of a rachis.

a. Spikes 10–50 in a long erect inflorescence; plants 3–10 dm. tall 1. *B. CURTIPENDULA*

a. Spikes 1–6; plants 1.5–5 dm. tall b

b. Leaf-blades glabrous; axis (rachis) of the spike not extending beyond the spikelet at the tip; back of 2nd glume with few tuberculate hairs (enlarged at the base), the hairs very short (mostly less than 1 mm. long) 3. *B. GRACILIS*

b. Leaf-blades with some hairs; axis (rachis) of the spike extending beyond the spikelet at the tip as a conspicuous projection; back of 2nd glume with numerous tuberculate hairs (enlarged at base), the hairs 1 mm. or more long 2. *B. HIRSUTA*

1. ***Bouteloua curtipendula*** (Michx.) Torr.

Sideoats Grama

Map 264

Flowers July–September.

Frequent on limestone glades, prairies, prairie openings in rocky woodland, grassy knolls, and along railroads. Throughout Missouri except absent in the southeastern lowland sector.

Ranges from Connecticut to Ontario west to

Montana, south to Georgia, Alabama, Mississippi, Louisiana, Texas, California, Mexico, Central America, and South America.

The plant receives its name from the oatlike drooping spikes which hang uniformly from the sides of the elongated axis. The ligule is a short (0.5 mm. long) band of hairs. This species is considered highly nutritious and is eaten by all classes of livestock. Since

PLATE NO. 48

265 *Bouteloua hirsuta* (Hairy Grama)266 *Bouteloua gracilis* (Blue Grama)267 *Buchloe dactyloides* (Buffalo Grass)

it does not shed much pollen, it is not considered as of much importance in causing hay fever.

2. ***Bouteloua hirsuta*** Lag. Hairy Grama Map 265
Flowers July–September.

Occurs on dry exposed loess hills of Holt and Atchison counties in northwestern Missouri, and locally east in Clark County, northeastern Missouri, where it is found on eroded slopes of a natural sandy prairie near the Mississippi River (T65N, R6W, sect. 9, 1½ mi. southeast of St. Francisville, Aug. 13, 1949, *Steyermark 68878*). At this latter unusual locality it was associated with *Bouteloua curtipendula*, *Cyperus Schweinitzii*, *Polygonum tenue*, *Astragalus distortus*, *Euphorbia glyptosperma*, and *Asclepias amplexicaulis*. On the loess mounds it is usually associated with species from the short grass plains region of the western United States, among them being *Muhlenbergia cuspidata*, *Yucca glauca*, *Anemone cylindrica*, *Oxytropis platensis*, *Astragalus lotiflorus*, *Psoralea argophylla*, *Dalea enneandra*, *Oenothera serrulata*, *Penstemon grandiflorus*, *Castilleja sessiliflora*, *Liatriis punctata*, *Lygodesmia juncea*, and *Lactuca pulchella*.

Ranges from Wisconsin to North Dakota and Colorado, south to western Illinois, Louisiana, Texas,

California, and Mexico; introduced eastward in Florida.

3. ***Bouteloua gracilis*** (HBK.) Lag.

Blue Grama

Map 266

According to Shinnars (Rh. 56: 31. 1954), the proper authorship for this species is *Bouteloua gracilis* (Willd.) Lag.

Flowers July–September.

Occurs on loess hills in Atchison and Holt counties of northwestern Missouri, on prairie knolls in Clay and Jackson counties of west-central Missouri, and along railroads in St. Louis County, east-central Missouri.

Ranges from Illinois, Wisconsin, Minnesota, and Alberta to British Columbia, south to Missouri, Texas, California, and Mexico; introduced eastward.

These species, together with *B. hirsuta*, are prominent members of the 'short grass' flora of the Great Plains region, along with other species of *Bouteloua*. In places where abundant, *B. gracilis* may be a contributing factor of slight importance in causing hay fever. It withstands extreme drouth and is highly palatable and nutritious for all classes of livestock.

57. ***Buchloe*** Engelm. Buffalo Grass

This genus is unusual in being usually dioecious (staminate and pistillate flowers on separate plants). These grasses are perennial and spread by stolons, which root at the nodes (joints). The pistillate spikelets are 1-flowered and closely clustered in a head-like 1-sided cluster. The staminate spikelets are 2–3-flowered, and somewhat resemble those of *Bouteloua*, occurring in 2 rows along 1 side of the spike.

Buchloe dactyloides (Nutt.) Engelm.

Buffalo Grass

Map 267

Flowers May–August.

Occurs on dry loess hills of Atchison and Holt

counties in northwestern Missouri, and in open ground and along railroads in Clay, Jackson, and St. Louis (Baden freight yard of the Mo.-Kan.-Topeka R. R., south of the yard office, St. Louis, June 22, 1957,

268 *Anthoxanthum odoratum* (Sweet Vernal Grass)269 *Phalaris canariensis* (Canary Grass)269A *Phalaris brachystachya*

Muehlenbach 1219; also July 5, 1958, *Muehlenbach* 1455) counties.

Ranges from Illinois, Iowa, Minnesota, Manitoba, Alberta, and Montana, south to Louisiana, Texas, and Mexico.

This species and *Bouteloua gracilis* exhibit the highest resistance to drouth of all the native American grasses. Buffalo grass is one of the most important, if not the most important, forage grass of the Great Plains re-

gion. In the western states the leaves and culms dry and cure on the ground, thereafter furnishing food all winter for the livestock.

Buffalo grass has been found to be unimportant so far as causing hay fever is concerned. It has been reported that the early settlers of the western United States prepared sod houses from the sod of buffalo grass.

Tribe VII. PHALARIDAE

Spikelets with 1 perfect terminal floret and, below this, 2 sterile (staminate) lemmas. Spikelets either falling in groups due to the articulation located below a group, or the spikelets individually articulated above the glumes and falling singly.

58. *Anthoxanthum* L. Sweet Vernal Grass

Inflorescence narrow and spike-like. Perennial grass (in local species) growing in tufts. Sterile lemmas large and awned from the back. Stamens 2. Lodicules none.

Anthoxanthum odoratum L.

Sweet Vernal Grass

Map 268

Flowers May–August.

Along railroads and waste ground. Known only from St. Louis, Iron, Boone, and Jackson counties.

Native of Europe; introduced into North America, ranging from Newfoundland to Ontario and Michigan, south to Georgia and Louisiana, and along the

Pacific Coast from Alaska southward.

This sweet-scented grass begins to flower in early May. Throughout much of its range it causes hay fever, and is, therefore, regarded as one of the most important hay fever grasses which cause trouble early in the season.

The dried plants may be boiled and used as a tea, the sweet fragrance of the plant adding to the flavor.

Plate no. 50. 1. *Hordeum vulgare*; a. Plant, $\times \frac{1}{5}$; b. Floret, $\times \frac{1}{5}$; c. Group of spikelets, $\times \frac{1}{5}$; d. Pistillate spikelet, $\times 2$; d. Staminate spikelet, $\times 2$.

PLATE NO. 50

59. **Phalaris** L. Canary Grass

Annual or perennial grasses with dense, lobed, or spike-like panicles. Ligule large and mostly very thin. Spikelets closely imbricated. Stamens 3. Lodicules present and noticeable.

- a. Inflorescence interrupted, branching or lobed; keel of glumes without any wing; perennials with creeping underground rhizomes; leaf-blades mainly 10–20 mm. wide 4. *P. ARUNDINACEA*
 a. Inflorescence continuous and dense, not interrupted; keel of glumes either with a broad wing or the wing narrow at the summit of keel; annuals, without creeping rhizomes; leaf-blades 4–10 mm. wide . . . b
 b. Inflorescence ellipsoid, tapering at each end, broadest in the middle, 1.5–12 cm. long; keel of glumes narrowly winged at summit; fruit 1 mm. wide 3. *P. CAROLINIANA*
 b. Inflorescence ovoid or broadly oblong, broadest in the lower half, 1.5–4 cm. long; keel of glumes broadly winged; fruit 2 mm. broad c
 c. Sterile lemmas 0.6 mm. long or less 2. *P. BRACHYSTACHYS*
 c. Sterile lemmas 1–2 mm. long, $1/3-1/2$ as long as the fertile lemma 1. *P. CANARIENSIS*

1. **Phalaris canariensis** L. Canary Grass,
 Birdseed Grass Map 269
 Flowers June–October.

Occurs infrequently as a waif in waste ground, along streets and roadsides, and railroads. Scattered in a few places in southern and central Missouri.

Native of Europe; introduced into North America, ranging from Newfoundland to Alaska, south to Florida, Texas, and California.

The plants vary in height from 3–8 dm. Although the canary seed sold for bird food comes from this grass, the plant is only rarely encountered as an escape, and does not appear to maintain or seed itself permanently.

It is stated that in its native country a meal, ground from the seeds, is made into a bread by the inhabitants, and that in Java young tender plants are eaten raw or cooked, combined with parts of other plants, with rice.

2. **Phalaris brachystachys** Link Map 269A
 Flowers May–July.

Known only from Laclede County, southern Missouri (Horseshoe Pond, June 30, 1938, *Geo. Moore*, in *Chi. Nat. Hist. Mus. Herb.*).

Native of the Mediterranean region; introduced in the United States, where known from Missouri, Texas, Oregon, and California.

The specimen was originally mistaken for *P. canariensis*, which it resembles, and has been identified correctly by Dennis Anderson.

3. **Phalaris caroliniana** Walt. Canary Grass
 Map 270
 Flowers May–June.

Occurs in sandy and open fields, waste and moist

ground, and along roadsides. Mainly found in western and extreme southeastern Missouri.

Ranges from Florida to Texas and Mexico, north to Maryland, Tennessee, Missouri, Kansas, Colorado, and Oregon.

The plants vary in height from 2–10 dm., but are usually 3–6 dm. tall.

4. **Phalaris arundinacea** L.

Reed Canary Grass Map 271
 Flowers last of April (southwest Missouri) to August.

Occurs in wet meadows, open ground along streams, open swales in alluvial ground around oxbow lakes and valleys of the large streams of northwestern Missouri and western Missouri. Common only in the northwestern and west-central sectors of the state, east to Macon and Linn counties, and locally south in Newton County (open ground along banks of Hickory Creek, Neosho, May 1, 1954, *Palmer 57441*; May 19, 1954, *Palmer 57560, 57573*; and June 29, 1954, *Palmer 58069*).

Ranges from Newfoundland to Alaska, south to Maryland, North Carolina, Kentucky, Illinois, Missouri, Oklahoma, New Mexico, Arizona, and California. Also in Eurasia.

In its early stages of flowering, this grass in the field or from a distance closely resembles the Orchard Grass (*Dactylis glomerata*). Both have crowded 1-sided groups of spikelets which vary from pale green to suffused with wine-purple. The leaves of *Dactylis* are narrower than those of *Phalaris arundinacea*, and the glumes and lemmas of *Dactylis* are more or less hairy, whereas those of *P. arundinacea* are glabrous, in addition to the technical differences.

Plate no. 51. 1. *Anthoxanthum odoratum*; a. Plant, $\times 3/8$; b, d. Sterile lemmas, $\times 3/4$; c. Fertile floret, $\times 3/4$; e. Spikelet, $\times 3/4$. 2. *Phalaris canariensis*; a. Plant, $\times 3/8$; b. Floret, $\times 3/4$; c. Spikelet, $\times 3/4$. 3. *Phalaris arundinacea*; a. Plant, $\times 3/4$; b. Floret, $\times 3/4$; c. Glumes, $\times 3/4$. 4. *Phalaris brachystachys*; a. Floret, $\times 3/4$; b. Glumes, $\times 3/4$. 5. *Phalaris caroliniana*; a. Plant, $\times 3/4$; b. Floret, $\times 3/4$; c. Glumes, $\times 3/4$.

PLATE NO. 51

270 *Phalaris caroliniana* (Canary Grass)271 *Phalaris arundinacea* (Reed Canary Grass)272 *Oryza sativa* (Rice)

This grass is an important lowland hay crop from Wisconsin to Montana. The species is sometimes planted as a forage plant, and the station in Newton County, southwestern Missouri, may represent an introduction or escape from cultivation. It is native, however, in the lowland swales and bottom meadows of northwestern Missouri. Once planted, it is consid-

ered a difficult weed to eradicate, in this respect resembling Johnson Grass.

A cultivated leaf variation, with white-striped blades, known as *P. arundinacea* var. *picta* L. (or f. *variegata* [Parnell] Druce), is sometimes escaped from gardens, but no records of such escapes are as yet known from Missouri.

Tribe VIII. ORYZEAE

Grasses of this tribe have 1-flowered perfect spikelets which are strongly flattened (laterally compressed). The glumes are greatly reduced in size or are not present. Stamens 1-6. The spikelet is articulated below the glumes.

60. *Oryza* L. Rice.

Usually annual grasses in our region. The narrow glumes are much shorter than the 5-nerved, keeled lemma.

Oryza sativa L. Rice.

Flowers June-September.

Map 272

Cultivated in the lowlands of southeastern Missouri, where occasionally escapes. The only known station, however, where rice has been collected as an escape in the state is from Marion County in northeastern Missouri, where a large number of plants were found in a dried-up depression (along the south side of highway 24, T59N, R6W, § sect. 1, just east of the city limits of Taylor, September 22, 1956, *Steyermark 82729*).

Presumably a native of southeastern Asia; cultivated in the southern United States and throughout

tropical and warm temperate regions of the world at low altitudes.

The Missouri station cited as an escape is farther north than the usual zone of cultivation. Inquiry concerning the cultivation of rice north of the Missouri River revealed the fact that hundreds of acres of rich alluvial Mississippi River flood plain north of Hannibal to the Iowa line are often cultivated for this crop.

Besides its importance as one of the principal cereals used by mankind, the dried straw is made into a pulp for paper making in China, Indonesia, Egypt, Spain, Italy, Brazil, Argentina, and the United States.

61. *Leersia* Sw. Cut Grass, White Grass.

Perennials, usually of wet or moist ground, the inflorescence paniculate, with the spikelets nearly sessile and arranged on 1 side of the branchlets. Glumes absent. The ligule is membranous.

- a. Spikelets 3-4 mm. wide, broadly oval to nearly round, more than half as wide as long. 1. *L. LENTICULARIS*
a. Spikelets 1-2 mm. wide, oblong, 1/4-1/3 as wide as long b

PLATE NO. 52

273 *Leersia lenticularis* (Catchfly Grass)274 • *Leersia oryzoides* f. *oryzoides* (Ricecut Grass)
274 □ *Leersia oryzoides* f. *inclusa*275 *Leersia virginica* (White Grass)

- b. Spikelets 1–1.3 mm. wide, 3–4 mm. long; leaves at most finely scabrous (rough with minute hairs) on margins and this not obvious; culms compressed (flattened); lower branches of inflorescence solitary 3. *L. VIRGINICA*
- b. Spikelets 1.5–2 mm. wide, 4.5–6 mm. long; leaves with bristly-ciliate or scabrous-hispid margins (with longer stiffer hairs) and this obvious; culms terete (circular in cross-section); lower branches of inflorescence whorled 2. *L. ORYZOIDES*

1. *Leersia lenticularis* Michx.

Catchfly Grass

Map 273

Flowers August–September.

Frequents border of sloughs and wooded swamps, bayous, margins of oxbow lakes and swales in river flood plain and valleys. Restricted to those sections of the state where its habitats occur: in the southeastern lowlands section, where common, sloughs and margins of wooded swamps and swales along the Mississippi River and tributaries in eastern Missouri, similar habitats especially around oxbow lakes in western and northwestern Missouri. Absent from practically the entire Ozark section.

Ranges from Florida to Texas, north to Maryland, Ohio, Indiana, Wisconsin, and Minnesota.

2. *Leersia oryzoides* (L.) Sw.

Ricecut Grass

Map 274

Flowers June–October.

Borders of sloughs, lakes, swamps, spring-fed rivulets in wet meadows, open swales, and ditches, but in situations usually exposed to sunlight.

Missouri material falls into two categories:

Inflorescence completely projecting from or partly included in the upper leaf-sheath

2a. *L. ORYZOIDES* f. *ORYZOIDES*

Inflorescence wholly or mostly included in or covered up by the upper leaf-sheath

2b. *L. ORYZOIDES* f. *INCLUSA*2a. *Leersia oryzoides* f. *oryzoides*

Map 274

The common type found throughout Missouri.

2b. *Leersia oryzoides* f. *inclusa* (Wiesb.)

Dörfler

Map 274

Occasionally associated with the typical form, but less common.

Some authors consider this latter f. *inclusa* as a mere late-season unexpanded growth stage, not worthy of taxonomic recognition. For a discussion of this subject see Fogg (Rh. 30: 81–85. 1928).

The rough leaf-blades of *L. oryzoides* and *L. lenticularis* can easily cut or tear the flesh if grabbed quickly or without caution.

3. *Leersia virginica* Willd. White Grass

Map 275

Flowers June–October.

Frequents usually moist or somewhat damp soil in woods, in ravines, valleys, along spring branches, borders of swamps, bayous, and rivers; usually associated with low woodland. Throughout Missouri.

Leersia virginica var. *ovata* (Poir.) Fern. was separated by Fernald (Rh. 38: 386. 1936) from var. *virginica* on the basis of having the margin of the lemma and often its keel bristly-ciliate with cilia up to 0.6 mm. long instead of being smooth or minutely ciliate. According to this distinction, both types of variations occur in Missouri. The variations, however, grade freely into one another and do not appear to show sufficient correlation in the material examined to be maintained.

276 *Zizania aquatica* var. *interior* (Water Rice)277 *Zizaniopsis miliacea* (Water Millet)278 • *Digitaria sanguinalis* var. *sanguinalis* (Crab Grass)
278 □ *Digitaria sanguinalis* var. *ciliaris*Tribe IX. **ZIZANIEAE**

The grasses in this tribe are monoecious with unisexual 1-flowered spikelets (either staminate or pistillate), the pistillate ones subulate or terete with united styles; the staminate ones have 6 stamens. Glumes are absent, and the spikelets are articulated below the glumes.

62. **Zizania** L. Wild Rice

Tall annual grasses growing in water, with long leaves and long, narrow, terminal panicles.

Zizania aquatica L. var. *interior* Fassett

Water Rice, Indian Rice, Wild Rice Map 276
Flowers June–October.

Frequents swamps and borders of ponds and streams. Very rare and local in Missouri, where it occurs in favored areas along the St. Francis, Mississippi, and Missouri rivers and their tributaries, locally elsewhere in Greene and Newton counties in southwestern Missouri.

Ranges from Indiana to North Dakota, south to Missouri and Texas.

The sole collection known from northern Missouri is from Clark County (Wayland, October 12, 1920,

F. P. Metcalf 1085) in the United States National Museum.

Although large amounts of pollen are shed by this plant, it is not an important one in the consideration of causes of hay fever.

This rice furnishes grain which is used in modern cookery as a breakfast food and as a substitute for ordinary rice usually served with fowl on special occasions. As the wild rice commands fairly high prices, it has not been used as much as it would otherwise. The grain was used by the Indians for flour for bread, for thickening soups, and to cook with wild meats.

63. **Zizaniopsis** Döll & Aschers. Water Millet

Tall perennial grasses, with creeping rhizomes, growing in the water.

Zizaniopsis miliacea (Michx.) Döll & Aschers.

Water Millet Map 277
Flowers April–August.

Frequent in sink-hole ponds of the Ozark region, and in swamps and borders of drainage ditches and bayous in the southeastern lowland section. Found only in southeastern Missouri west to Shannon and Oregon counties and north to New Madrid and Stoddard counties.

Ranges from Florida to Texas, north to Maryland, Kentucky, southeast Missouri, and Oklahoma. Also in Mexico and South America.

The leaves of this grass are razor-sharp, easily

cutting the flesh when handled; they are long and erect, 3–10 dm. long and 1–3 cm. wide. The plants, which vary from 1–4 meters high, often occur in dense colonies. At a distance they somewhat resemble sugar cane.

It has been suggested that the young tips of the rhizomes of this species, when cooked, would make a desirable cooked vegetable, in much the same manner in which the Chinese use a species of *Zizania* native to China and Japan; this is either cooked with meat or cut into two or three pieces which are boiled and served with melted butter as a vegetable.

Tribe X. PANICEAE

Grasses of this tribe have the articulation of the spikelets below the glumes. The spikelets consist of 1 perfect floret with 2 often thin or membranous glumes, a sterile lemma similar to the glumes in texture and resembling a 3rd glume, and a thicker rather tough fertile lemma and palea together covering the grain or seed-like fruit. Spikelets are more or less dorsally compressed.

64. *Digitaria* Heist. Crab Grass

Annual grasses (in the local species) with a digitate or nearly digitate inflorescence. Spikelets in 2 rows on 1 side of the rachis, 1-flowered with the 1st glume very small or lacking.

- a. The axis (rachis) of each ray or spoke of the inflorescence very narrowly winged, the wings narrower than the main rib of the rachis 3. *D. FILIFORMIS*
- a. The axis (rachis) of each ray or spoke of the inflorescence broadly winged, the wings wider than or as wide as the main rib of the rachis (resembling a divided highway) b
- b. At least the lower leaf-sheaths and blades more or less conspicuously hairy; spikelets 2.3–3.5 mm. long; spikelets glabrous between the smooth or finely hairy nerves 1. *D. SANGUINALIS*
- b. Leaf-sheaths and blades mostly glabrous, a few hairs sometimes on lower sheaths; spikelets 1.7–2.2 mm. long; at least some of the spikelets with few to many short spreading hairs between the nerves 2. *D. ISCHAEMUM*

1. *Digitaria sanguinalis* (L.) Scop.

Crab Grass

Map 278

Flowers July–November.

Waste and cultivated ground, frequently in lawns, gardens, margins of ponds, spring branches, rocky open ground, prairie openings, and along railroads and roadways. Throughout Missouri.

Native of Europe; introduced in North America, where found throughout the United States and southern Canada.

Missouri material may be divided into two varieties:

Spikelets 2.3–3 mm. long, the hairs on the marginal nerves of the sterile lemma minute

1a. *D. SANGUINALIS* var. *SANGUINALIS*

Spikelets 3–3.5 mm. long, the hairs on the marginal nerves of sterile lemma longer and more conspicuous 1b. *D. SANGUINALIS* var. *CILIARIS*

1a. *Digitaria sanguinalis* var. *sanguinalis*

Map 278

The common type encountered.

1b. *Digitaria sanguinalis* var. *ciliaris* (Retz.)

Parl.

Map 278

Digitaria sanguinalis var. *marginata* (Link) Fern. [P & S]

Known from Ray, Stoddard, and Dunklin counties.

Although *D. sanguinalis* is very widespread, it does

not appear to be of any importance in causing hay fever. It is considered a good forage plant for late summer, but more often is condemned because of being a weed in lawns and gardens. It often roots at the lower nodes (joints) of the stem, producing a large colony from one plant. Various chemicals (phenyl mercury acetate, potassium cyanate, and disodium methyl arsonate obtained on the market under trade names) are used to control crab grass, when it becomes a nuisance. Some chemicals, such as calcium cyanimid, applied, before seeding, kill the weed seeds before they have sprouted and also act as a fertilizer. The inflorescences are green or often turn dull purple; parts of the culms and sometimes the leaf blades are also purple or tinged with purple.

The seeds have been cultivated and used in some parts of Europe, such as Poland, as a substitute for rice.

2. *Digitaria Ischaemum* (Schreb.) Muhl.

Crab Grass

Map 279

Flowers July–November.

Frequent in moist low ground of fields, cultivated valleys along river bottoms, pastures, meadows, low woodlands, roadsides, and waste ground. Found in lawns and garden soils, but less frequent, for the most part, in such places than *D. sanguinalis*.

Throughout Missouri.

Native of Europe; introduced into North America,

Plate no. 53. 1. *Leptoloma cognatum*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$. 2. *Digitaria filiformis*; a. Plant, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c. Spikelet, $\times \frac{7}{12}$. 3. *Digitaria Ischaemum*; a. Plant, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c. Spikelet, $\times \frac{7}{12}$. 4. *Digitaria sanguinalis*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$.

PLATE NO. 53

279 • *Digitaria ischaemum* var. *ischaemum* (Crab Grass)
279 □ *Digitaria ischaemum* var. *mississippiensis*

280 • *Digitaria filiformis* var. *filiformis* (Slender Crab Grass)
280 □ *Digitaria filiformis* var. *villosa*

281 *Leptoloma cognatum* (Fall Witch Grass)

ranging from Quebec to North Dakota and Washington, south to Florida, Louisiana, Texas, and California.

Missouri material falls into two categories:

The 1–6 branches (spikelike racemes) of inflorescence 1–9 cm. long; leaf-blades 2–10 cm. long, 3–8 mm. wide. . . 2a. *D. ISCHAEMUM* var. *ISCHAEMUM*
The 5–8 branches (spikelike racemes) of inflorescence 6–15 cm. long; leaf-blades up to 20 cm. long, 6–9 mm. wide 2b. *D. ISCHAEMUM* var. *MISSISSIPPIENSIS*

2a. ***Digitaria ischaemum* var. *ischaemum***

Map 279

The commoner variation found in Missouri, throughout the state.

2b. ***Digitaria ischaemum* var. *mississippiensis*** (Gattinger) Fern.

Map 279

Scattered throughout the state.

There is much intergradation between the two variations, which are distinct in their extremes. In general the inflorescence branches are shorter and the leaf-blades shorter and narrower in *D. ischaemum* var. *ischaemum*. The culms are generally more spreading than in *D. sanguinalis* var. *sanguinalis*, although they may be erect to prostrate in the extreme with rooting nodes, and the plants as a whole are often paler green, but are also tinged purple on various parts. The culms generally are more slender and shorter than those of *D. sanguinalis*.

Plants are sometimes found having some of the spikelets typically covered with hairs between the nerves, with other spikelets of the same inflorescence glabrous.

Rarely are found inflorescences which have the spikelets proliferating on branched stalks. Such spec-

imens are *Steiermark 80682* from Barry County, southwestern Missouri.

3. ***Digitaria filiformis* (L.) Koel.**

Slender Crab Grass

Map 280

Flowers August–October.

Occurs on sandstone and chert glades and prairies, sandy fields, valleys, and roadsides, where rather infrequent in southern and central Missouri. It is characteristic of acid sterile soils in dry open areas.

Missouri material falls into two varieties:

Spikelets 1.5–2 mm. long; lower leaf-sheaths glabrous to sparsely hairy. 3a. *D. FILIFORMIS* var. *FILIFORMIS*

Spikelets 2–2.6 mm. long; lower leaf-sheaths densely and conspicuously hairy . . . 3b. *D. FILIFORMIS* var. *VILLOSA*

3a. ***Digitaria filiformis* var. *filiformis*** Map 280

The commoner variation in Missouri, extending north to Jackson, Boone, and St. Louis counties.

Ranges from Florida to Texas and Mexico, north to New Hampshire, New York, Michigan, Illinois, and Iowa.

3b. ***Digitaria filiformis* var. *villosa* (Walt.)**

Fern.

Map 280

Scattered in southern and east-central Missouri.

Ranges from Florida to Texas, north to Virginia, Tennessee, Illinois, Missouri, and Kansas.

The rachis of the inflorescence branches is much narrower than in either of the other species in Missouri. Generally, the culms are more erect and ascending, and do not possess the decumbent or rooting habit of *D. sanguinalis* or spreading to prostrate habit of *D. ischaemum*. The culms (stems) in *D. filiformis* are the slenderest of the three species found in Missouri. Tiny gland-tipped hairs occur on the glumes and sterile lemma of this species.

282 *Eriochloa contracta* (Prairie Cup Grass)283 *Eriochloa gracilis* var. *gracilis* (Cup Grass)

284 Excluded species

65. **Leptoloma** Chase Fall Witch Grass

Perennial grasses with spindle-shaped (fusiform) spikelets on long hair-like pedicels (stalks). The 1st glume is minute or lacking. The culms are brittle and, when mature, break up easily.

Leptoloma cognatum (Schultes) Chase

Fall Witch Grass Map 281
Flowers June–October.

Frequent along roadsides, waste places, railroads, prairies, glades, pastures, and sandy areas. Mostly in the southern half of the state, not recorded from northwestern Missouri, north and west to Clark, Sullivan, Livingston, and Caldwell counties.

Ranges from Florida to Mexico and Arizona, north to New Hampshire, New York, Ohio, Michigan, Wisconsin, Minnesota, and Nebraska.

This grass becomes much branched at the base, producing a sprawling many-stemmed plant. The

many-branched, graceful panicle, which occupies a third to half the height of the plant, takes on a lively rose-purple color and eventually breaks away from the rest of the plant as a tumbleweed. The mass color effect of these plants along highways and pastures is quite striking.

Plants of this genus are often mistaken for species of *Panicum* from which they are separated by the ligule, which is a collarlike hairless scale, not hairy or hairy-fringed as in *Panicum*, and by the thin and flexible fertile lemma with a colorless (hyaline) margin which is not inrolled, rather than a hard firm fertile lemma inrolled on the margins as in *Panicum*.

66. **Eriochloa** HBK. Cup Grass

Annual or perennial grasses, with a long, narrow, dense inflorescence (panicle) of racemes appressed to the main axis. The inflorescence is often at first partly enclosed in or covered by the upper leaf-sheath.

Leaf-blade pubescent, 4-7 mm. wide; spikelets 3.5-4 mm. long 1. *E. CONTRACTA*
 Leaf-blade glabrous, 5-10 mm. wide; spikelets 4-5 mm. long 2. *E. GRACILIS*

1. **Eriochloa contracta** Hitchc.

Prairie Cup Grass
Flowers July–October.

Cultivated and waste ground, often in alluvial ground of fields and river valleys, where rather rare in central and eastern Missouri, following the Mississippi and Missouri rivers.

Ranges from Missouri (where introduced) and Kansas to Louisiana, Texas, and New Mexico; introduced in Virginia.

The two species treated are very similar. *Eriochloa contracta*, which is the commonest of the two in Missouri, has the fruit tipped by an awn about 1 mm.

long, and is an annual.

2. **Eriochloa gracilis** (Fourn.) Hitchc. var. **gracilis**
Cup Grass Map 283

Flowers July–October.
Cultivated and alluvial ground.

Known only from southeastern Missouri, in Mississippi County (open places bordering soybean fields) along road K, T27N, R16E, sect. 24, 7½ mi. [by air] northeast of Charleston, August 21, 1955, *Steyermark 79553*).

Ranges from Texas to California and Mexico; introduced in Missouri.

285 *Brachiaria platyphylla*286 *Brachiaria erucaiformis*287 *Paspalum dissectum*67. *Brachiaria* (Trin.) Griseb.

Annual (in the local species) grasses with the inflorescence of several spreading or appressed racemes arranged racemose or pinnate along the main axis. The spikelets are placed with the back of the fruit turned away from the rachis of the racemes. First glume present.

Spikelets glabrous, 4–4.5 mm. long 1. *B. PLATYPHYLLA*
Spikelets pubescent, 2–2.5 mm. long 2. *B. ERUCAIFORMIS*

1. *Brachiaria platyphylla* (Griseb.) Nash

Map 285

Brachiaria extensa Chase (Hitchcock, ed. 1)

Flowers August–November.

Cultivated low fields, sandy open knolls, and borders of wet ditches along roads in the southeastern lowland region of Missouri, where known only from Scott (edge of field in lowland and on sandy ridge top at edge of field, T27N, R13E, sect. 12, 4½ mi. east of Vanduser, November 1, 1956, *Steiermark 83578*) and Pemiscot (openings along ditch, along road E, sect. 8, 1½ mi. east of Cooter, October 23, 1948, *Steiermark 67054*) counties.

Ranges from Florida to Texas, north to southeastern Missouri and Oklahoma.

2. *Brachiaria erucaiformis* (J. E. Smith)

Griseb.

Map 286

Flowers October.

Known only from southwestern Missouri in Stone County (gravel bed of Creek, between Aunt's Creek and James River, T23N, R23–24W, sect. 31, 36, and north part of sect. 1, 4½–5 mi. [by air] northwest of Radical, 6–7 mi. northeast of Baxter, Oct. 20, 1955, *Steiermark 80556*).

Native to the Old World (India west to Spain); escaped from cultivation in a few places in the United States.

The locality where this species was found is now exterminated, being part of the impounded waters of Table Rock Dam.

68. *Paspalum* L.

Perennial (in the local species) grasses with soft leaves and an inflorescence of 1–several racemes arranged digitately, pinnately, or rarely solitarily. The almost round to ovate spikelets, which articulate below the glumes, are in 2 or 4 rows on 1 side of the rachis and are flat on one side, curved on the other (plano-convex), with a somewhat flattened appearance. The first glume is usually lacking.

- a. Rachis (axis) of each ray or spoke (raceme) of the inflorescence broad, winged, or leaf-like, and wider than the spikelets themselves b
b. Rays (racemes) 5–50; spikelets 1.1–1.7 mm. long, with tiny hairs; leaf-blades 3–25 mm. wide (mostly 6 or more) 2. *P. FLUITANS*
b. Rays (racemes) 1–4 (sometimes 5); spikelets 1.8–2.3 mm. long, glabrous (without hairs); leaf-blades 2–5 mm. wide 1. *P. DISSECTUM*

Plate no. 54. 1. *Paspalum dissectum*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$. 2. *Brachiaria platyphylla*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$. 3. *Eriochloa gracilis*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$. 4. *Eriochloa contracta*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$. 5. *Brachiaria erucaiformis*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$.

PLATE NO. 54

288 *Paspalum fluitans*289 *Paspalum pubiflorum* var. *glabrum*290 *Paspalum setaceum* var. *setaceum*

- a. Rachis (axis) of each ray or spoke (raceme) of the inflorescence narrow or without wings, always narrower than the rows of spikelets c
- c. Some part of spikelet with conspicuous silky hairs; spikelet conspicuously pointed at tip (acute to acuminate); tip flexible, not ending uniformly, one part of tip (of glume and sterile lemma) distinctly longer than other part of tip (fertile lemma) 7. *P. DILATATUM*
- c. Spikelet glabrous or at most with tiny short hairs; spikelet rounded or blunt at tip, the tip firm and ending uniformly on all sides d
- d. Each spikelet attached singly to 1 pedicel (stalk) along the rachis 8. *P. LAEVE*
- d. Spikelets arising in pairs, the pedicel forking at the base (the 2nd spikelet sometimes poorly or not developed) e
- e. Spikelets 3.6–4.3 mm. long, 2.8–3.1 mm. wide 9. *P. FLORIDANUM*
- e. Spikelets 1.4–3.2 mm. long, 1.3–2.4 mm. wide f
- f. Spikelets 2.9–3.2 mm. long 3. *P. PUBIFLORUM*
- f. Spikelets 1.4–2.8 (–3) mm. long g
- g. Spikelets 1–1.6 mm. wide, ellipsoid, about $\frac{3}{4}$ as wide as long 4. *P. SETACEUM*
- g. Spikelets mostly 1.5–2.4 mm. wide, round or nearly round in outline h
- h. Spikelets densely hairy; leaves densely soft, short-hairy and mixed with long hairs; nodes (joints) of culms mostly hairy 6. *P. BUSHII*
- h. Spikelets mostly glabrous or with a few short hairs; leaves glabrous, long hairy, or minutely hairy (puberulent) and mixed with long hairs; nodes (joints) of culms glabrous 5. *P. CILIATIFOLIUM*

1. *Paspalum dissectum* L.

Map 287

Flowers July–October.

Muddy banks of streams, ditches, and sloughs, and margins of upland ponds. Rare, and found only in southern Missouri in the southeastern lowland section, around an upland sink-hole pond in Howell Co., and in Jasper (*Palmer 968, 969*) and Barton (*Palmer 55318*) counties of southwestern Missouri.

Ranges from Florida to Texas, north to New Jersey, Tennessee, southern Illinois and southern Missouri, and also in Cuba.

2. *Paspalum fluitans* (Ell.) Kunth

Map 288

Paspalum repens of some authors, not Bergius [P & S, Hitchcock, ed. 1]

Wet muddy alluvial banks along streams, bayous, sloughs, and margins of lakes and ponds, especially oxbow lakes in the valleys of large rivers. Restricted to various sections of southern, central, and eastern Missouri, the southeastern lowland section, alluvial

ground of the White River in southwestern Missouri (now dammed), along sections of the Missouri, Osage, Clear Creek, South Grand, Marmaton, Marais des Cynes, and their oxbow lakes, and locally north of the Missouri River in Chariton and Marion counties.

Ranges from Florida to Texas north to Virginia, Kentucky, Indiana, Illinois, Missouri, and Kansas.

3. *Paspalum pubiflorum* Rupr. var. *glabrum*

Vasey

Map 289

Flowers June–September.

Occurs in moist open ground, prairie swales, meadows, borders of sandy wet ditches, sandy roadsides and open fields, alluvial woods, and along railroads, in southern and central Missouri north to Cass, Johnson, Boone, Gasconade, and St. Louis counties.

Ranges from Florida to Texas, north to North Carolina, Kentucky, Ohio, Indiana, Illinois, Missouri, and Kansas.

This species may be distinguished vegetatively by

291 • *Paspalum ciliatifolium* var. *ciliatifolium*
291 x *Paspalum ciliatifolium* var. *Muhlenbergii*
291 □ *Paspalum ciliatifolium* var. *stramineum*

292 *Paspalum Bushii*

293 *Paspalum dilatatum* (Dallas Grass)

the decumbent and geniculate rooting lower nodes of the culms as contrasted with another tall-growing species, *P. floridanum*, in which the culms are erect, but do not root at the lower nodes.

Typical *P. pubiflorum* var. *pubiflorum*, with pubescent spikelets, occurs in some of the southern states, Mexico, and the West Indies.

4. ***Paspalum setaceum* Michx. var. *setaceum***

Map 290

Flowers June–October.

Known only from Crowley Ridge, southeastern Missouri in Stoddard County (dry sandy wooded slopes bordering ravines along and tributary to spring-fed creek near junction of Crowley Ridge and lowland, on property of Mr. Martin, T₂₅N, R₁₁E, NW $\frac{1}{4}$ sect. 6, $3\frac{1}{2}$ mi. southeast of Bloomfield, August 20, 1954, *Steyermark* 76726).

Ranges from Florida to Texas, north to Massachusetts, New York, Ohio, Kentucky, and Missouri.

The variety occurring in Missouri is the typical one, distinguished by the relatively small spikelets, 1.4–1.8 mm. long, 1–1.2 mm. wide, and by the densely hairy leaf-blades 2–6 mm. wide.

The culms (stems) of this species are very slender and filiform. The 1–3 slender racemes of the inflorescence have a very slender rachis, which is much narrower than any of the other species in Missouri.

5. ***Paspalum ciliatifolium* Michx.**

Map 291

Flowers late May–October.

Occurs in prairies, roadside banks, along railroads, border of woods, grazed fields and pastures, and dry open woods. Throughout Missouri.

Missouri material falls into the following categories:

- a. Upper surface of leaf-blade with 2 lengths of hair, with many minute hairs (puberulence)

between longer hairs . . . 1c. *P. CILIATIFOLIUM* var. *STRAMINEUM*

- a. Upper surface of leaf-blade entirely glabrous, or else long-hairy with one length of long hair . . . b

b. Upper surface entirely glabrous . . . 1a. *P. CILIATIFOLIUM* var. *CILIATIFOLIUM*

b. Upper surface with long hairs of about the same length . . . 1b. *P. CILIATIFOLIUM* var. *MUHLENBERGII*

5a. ***Paspalum ciliatifolium* var. *ciliatifolium***

Map 291

Paspalum ciliatifolium Michx. [G, P & S]

Known in only a few southern counties and northwest in Jackson County.

Ranges from Florida to Texas, north to D. C., Tennessee, and Missouri.

5b. ***Paspalum ciliatifolium* var. *Muhlenbergii*** (Nash) Fern.

Map 291

The common type found throughout the state.

Ranges from Florida to Texas, north to New Hampshire, New York, Ohio, Michigan, and Wisconsin.

5c. ***Paspalum ciliatifolium* var. *stramineum*** (Nash) Fern.

Map 291

Scattered over the state, infrequent.

Ranges from Texas to Arizona, north to Indiana, Wisconsin, Minnesota, Nebraska, and Colorado.

Although it is possible to separate the above variations as such, intergradation is found in the amount of pubescence of the leaf-blades, height of culm, erect or spreading habit, and glabry of the spikelet. Deam (*Grasses of Indiana*, p. 234. 1929) believes that much of the variation in leaf pubescence and habit might be due to the effects of grazing. Shinnors (Rh. 56: 32. 1954) does not believe that these variations in Texas merit varietal names and places them all together as *P. ciliatifolium*.

Most of the Missouri material falls under *P. ciliatifolium* var. *Muhlenbergii*. The other variations are found infrequently.

6. ***Paspalum Bushii*** Nash Map 292
Paspalum ciliatifolium var. *stramineum* [of BB, P & S],
 not (Nash) Fern.

Sandy open woods, sandy open places, and in fields, rare in southern and central Missouri north to Jackson and St. Charles counties. The species is based upon a Missouri collection (Bernie, Stoddard County, *Bush* 730).

Ranges from Illinois and Missouri to Nebraska and Texas.

Some authors (Shinners, Gleason, Hitchcock) consider this species inseparable from *P. ciliatifolium* var. *stramineum*. Although variation does exist in *P. Bushii*, it is maintained in the present treatment on the basis of a combination of characters including pubescent nodes of the culms, densely soft pubescent leaf-blades on both surfaces with appressed long pubescence, and densely pubescent spikelets.

7. ***Paspalum dilatatum*** Poir.
 Dallis Grass, Water Paspalum Map 293
 Flowers May–October.

Known only from St. Louis (right-of-way of Wabash R. R., north of Palm St. along the most western track, St. Louis, September 8, 1957, *Muehlenbach* 1355; also September 1, 1958, *Muehlenbach* 1478) and Newton (along spring branch, 4 mi. south of Saginaw, August 13, 1957, *Palmer* 66230) counties.

Native of South America from Brazil to Argentina; introduced into Central America, the West Indies, and the Old World; in the United States introduced and ranging from Florida to California, north to Virginia, Tennessee, Missouri, Colorado, and Oregon.

Introduced into the southern United States about 1850 as a pasture grass. It is believed to be a contributing cause of hay fever at the time it is in flower between spring and fall.

8. ***Paspalum laeve*** Michx. Map 294
 Flowers July–October.

Occurs in wet places in prairies, fields, marshy ground at the base of slopes, along ditches, moist open ground, borders of lakes and bayous, and along roadsides and railroads.

Missouri material may be segregated as follows:

- a. Spikelets more or less circular or orbicular, 2.8–3.2 mm. wide . 8b. *P. LAEVE* var. *CIRCULARE*
 a. Spikelets slightly longer than wide, 2–2.5 mm. wide b
 b. Leaf-sheaths and blades glabrous or nearly glabrous 8a. *P. LAEVE* var. *LAEVE*
 b. Leaf-sheaths strongly hairy; leaf-blades often quite hairy . 8c. *P. LAEVE* var. *PILOSUM*

- 8a. ***Paspalum laeve*** var. *laeve* Map 294
Paspalum laeve Michx. [G]
Paspalum laeve in part [BB]

Rare, known only from Cape Girardeau (*Steyermark* 64158), Bollinger, Stoddard (*Steyermark* 66187), Ripley (*Steyermark* 64158), and Stone counties.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Ohio, Illinois, and Missouri.

- 8b. ***Paspalum laeve*** var. *circulare* (Nash) Fern. Map 294
Paspalum laeve in part [BB]

Frequent in southern and central Missouri north to Jackson, Boone, Shelby, and Lincoln counties. This is the commonest of the variations in Missouri.

Ranges from Georgia to Texas, north to Connecticut, New York, Pennsylvania, Indiana, Illinois, Missouri, and Kansas.

- 8c. ***Paspalum laeve*** var. *pilosum* Scribn. Map 294
Paspalum laeve in part [BB]

Scattered in southern Missouri, extending north to Barton, Polk, Phelps, and Washington counties.

Ranges from Florida to Texas north to New York, Pennsylvania, Tennessee, and Missouri.

The range of variation in *P. laeve* is considerable, with intergradation occurring as in *P. ciliatifolium* and other species. Some authors, such as Gleason in the *New Illustrated Flora*, find no correlation between the variations and do not believe the variations warrant recognition.

The branches (racemes) of the inflorescence vary from 2–8 and have a rachis about 1 mm. wide.

9. ***Paspalum floridanum*** Michx. Map 295
 Flowers August–October.
 Occurs in wet meadows, swales in prairies, margins

Plate no. 55. 1. *Paspalum dilatatum*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$. 2. *Paspalum fluitans*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$. 3. *Paspalum setaceum*; a. Raceme, $\times \frac{3}{4}$; b. 296 *Panicum depauperatum* var. *depauperatum* (Panic Grass)

of upland sink-hole ponds, sandy fields, along streams, in ravine bottoms, ditches, and roadsides.

Missouri material falls into two categories:

Leaf-sheaths hairy; leaf-blades hairy

9a. *P. FLORIDANUM* var. *FLORIDANUM*

Leaf-sheaths and blades glabrous or nearly so

9b. *P. FLORIDANUM* var. *GLABRATUM*

9a. ***Paspalum floridanum* var. *floridanum***

Map 295

This is less common in Missouri than the other variety, and is known from southern Missouri only from Mississippi, Oregon, Howell, Polk, Barton, Jasper, and Newton counties.

Ranges from Florida to Texas, north to Virginia, Tennessee, Missouri, and Oklahoma.

9b. ***Paspalum floridanum* var. *glabratum***

Engelm.

Map 295

Scattered in southern Missouri from Stoddard County to Polk and Vernon counties.

Ranges from Florida and Texas, north to New Jersey, Pennsylvania, Missouri, and Kansas.

Paspalum floridanum and *P. pubiflorum* are the tallest of the species of *Paspalum* in Missouri, attaining a height of about 2 meters; *P. floridanum* averages taller plants more frequently than *P. pubiflorum*. Both have robust culms.

Plate no. 56. 1. *Paspalum floridanum*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$. 2. *Panicum perlongum*; a. Two views of spikelet, $\times \frac{7}{12}$. 5. *Paspalum laeve* var. *circulare*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$. 6. *Paspalum laeve* var. *laeve*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$.

PLATE NO. 56

69. *Panicum* L. Panic Grass

Annual or perennial grasses, the culms (stems) usually not fracturing, the axis of the inflorescence remaining long after maturity. The 1-flowered spikelets, which articulate below the glumes, have a thin 2nd glume and sterile lemma, and a hard, firmer, thickened fertile lemma.

This is a large group, some species of which are very distinct, others quite involved and difficult to separate. Differences of 0.1–0.5 mm. in the length or width of the spikelets are important in separating a number of the species, so that great care in measuring the spikelets is especially necessary to exercise in this genus.

The genus is divided into two main groups (1) those species having the leaves at the base of the plant similar to those of the culms (stem), the plants not forming rosettes of winter leaves, and (2) those species having the leaves at the base of the plant unlike or different from those of the culm, the plants forming rosettes of winter leaves. The first group includes annuals as well as perennials, the second group perennials only. In this second group of winter-rosette forming perennials, the plants generally flower twice, at first in the spring producing the *vernal* panicles with chiefly simple unbranched culms which become much branched in summer and fall with *autumnal* panicles occurring along the sides or from the axils of the leaf-sheaths;* and, then in fall developing a rosette of leaves which are broader than those of the culm and persist over winter. Plants pertaining to the group of winter-rosette leaves are frequently collected in summer or other times of the year without these basal leaves much in evidence. This is due sometimes to the obtaining of hastily or incompletely collected specimens, and at other times due to the drying up of the lowest leaves or to collecting the plants before the rosette leaves are well developed.

- a. All the spikelets densely crowded together into unbranched spike-like, erect to ascending racemes which occur alternately along the main axis of the inflorescence, the whole inflorescence giving the appearance of being pinnately arranged on 2 sides of a main axis *b*
- b. Spikelets 5–6 mm. long 32. *P. TEXANUM*
- b. Spikelets 2.2–3.8 mm. long *c*
- c. Spikelets 3–3.8 mm. long, about 2 mm. wide, rounded or obtuse at tip; fruit smooth 44. *P. OBTUSUM*
- c. Spikelets 2.2–2.4 mm. long, 1.3–1.5 mm. wide, acutely pointed at tip; fruit cross-wrinkled or rugose 31. *P. GEMINATUM*
- a. Inflorescence (panicle) with some or all of the side branches outwardly spreading, the inflorescence as a whole with the shape either of a narrow to broad triangle, pyramid, spire, or Christmas tree, or with the lower branches often longer and more spreading, or the inflorescence as broad as or broader than long *d*
- d. Most of leaf-blades erect, crowded, and appearing to come from the base of the plant (due to the very much shortened lower internodes) *e*
- e. Spikelets acutely pointed with an obvious beak at tip, mainly 3–4.5 mm. long 1. *P. DEPAUPERATUM*
- e. Spikelets mostly rounded or obtuse (blunt) at tip, not beaked, 1.7–3.5 mm. long *f*
- f. Leaf-blades firm and rather thick, long, mainly 1–5 mm. wide, more than 20 times as long as wide; spikelets mainly 2–3.5 mm. long, 1.2–2 mm. wide; ligule a band of hairs 0.5–1 mm. long; culms and nodes usually pubescent *g*
- g. Spikelets 2.7–3.5 mm. long, 1.6–2 mm. wide; branches of inflorescence erect or strongly ascending, closely appressed to the main axis of inflorescence, side branches mostly simple or little branched, the inflorescence often only 0.5–1 cm. wide; spikelets relatively few, averaging 10–20 to an inflorescence. 2. *P. PERLONGUM*
- g. Spikelets mainly 2–3 mm. long, 1.1–1.5 mm. wide; lower branches of inflorescence usually branched, usually spreading or ascending so that they appear separated and extending out from main axis, the inflorescence mainly 2–3 cm. wide; spikelets frequently averaging 20–35 to an inflorescence, sometimes only 15 *h*
- h. Leaf-sheaths hairy 3a. *P. LINEARIFOLIUM* var. *LINEARIFOLIUM*
- h. Leaf-sheaths entirely or mainly glabrous 3b. *P. LINEARIFOLIUM* var. *WERNERI*
- f. Leaf-blades thin and soft, mainly 5–12 mm. wide, mostly 10–15 times as long as wide; spikelets 1.7–2.1 (–2.6) mm. long, 0.9–1.2 mm. wide; ligule nearly obsolete, less than 0.5 mm. long; culms and lower nodes glabrous 4. *P. LAXIFLORUM*

* In the information on flowering given for each species, following the key to species, *vernal* indicates the first flowering, *autumnal* the second flowering.

- d. Most of leaf-blades more or less scattered from bottom to above the middle of culm, either horizontally spreading, ascending or erect, not appearing more bunched at the base than on the culm . . . *i*
- i. Lemmas and glumes of spikelets themselves glabrous (but sometimes with delicate bristles at base on outside of spikelet in *P. agrostoides*); plants blooming only once during the season, all the inflorescences produced at the same period . . . *j*
- j. Spikelets 4.5–6 mm. long . . . *k*
- k. Leaf-sheaths glabrous; inflorescence as a whole erect with spreading widely spaced branches . . . 39. *P. VIRGATUM*
- k. Leaf-sheaths pubescent; inflorescence as a whole nodding or drooping with closely crowded ascending branches (not obvious in dried, pressed state where it appears erect). 38. *P. MILLIACEUM*
- j. Spikelets less than 4.5 mm. long . . . *l*
- l. Spikelets short-to-slender-pointed (acute to acuminate) at tip; basal leaves similar to leaves on culm (stem), all long and narrow; basal leaves often numerous, but not forming a winter rosette . . . *m*
- m. Most of leaf-sheath glabrous (except at very summit); nodes of culms (stems) glabrous . . . *n*
- n. First glume broadly triangular or rounded-deltoid, sloping to a curving or barely pointed summit, $1/5$ – $1/3$ the length of the spikelet; annuals with a tuft of roots at base; stems often conspicuously zig-zag . . . 33. *P. DICHOTOMIFLORUM*
- n. First glume rather sharply pointed to a V-shaped tip, acute to acuminate, $1/3$ – $7/8$ length of spikelet; perennials; stems usually not zig-zag . . . *o*
- o. Culms (stems) terete (round in cross section), not compressed or flattened; leaf-sheaths rounded, not keeled; ligule densely hairy-fringed, 2–4 mm. long; spikelets appearing on different sides of the divisions of the inflorescence. . . 39. *P. VIRGATUM*
- o. Culms (stems) compressed and/or leaf-sheaths keeled; ligule minute or at most a jagged membrane 0.5–1 mm. long; spikelets either obliquely curved or turned at an angle to the stalk of spikelet or chiefly secund or nearly secund (all turned to the same side or direction) along one side of the axis of the divisions of the inflorescence . . . *p*
- p. Spikelets obliquely curved or turned at an angle to the pedicel (stalk) of spikelet; spikelets mainly 3–4 mm. long . . . 42. *P. ANCEPS*
- p. Spikelets straight, not curved nor turned at an angle to the pedicel; spikelets 1.7–2.8 mm. long . . . *q*
- q. Spikelets 2.4–2.8 mm. long; fruit with a basal stalk 0.2–0.4 mm. long . 41. *P. STIPITATUM*
- q. Spikelets 1.7–2.4 mm. long; fruit without any basal stalk or the stalk less than 0.2 mm. long . . . *r*
- r. Culms wiry, slender, 1–2 mm. wide below middle; ligule minute; fruit minutely papillose-roughened; leaf-blades 1–5 (rarely 6) mm. wide; inflorescence mainly 2–12 cm. long (rarely longer) . . . 43. *P. HIANs*
- r. Culms stout, 3–6 mm. wide below the middle; ligule a jagged-edged membrane 0.5–1 mm. long; fruit smooth and shining; leaf-blades mainly 5–12 (rarely 4) mm. wide; inflorescence mainly 10–40 cm. long (rarely shorter). . . 40. *P. AGROSTOIDES*
- m. Most of leaf-sheath conspicuously hairy; nodes of culm (stem) with spreading or appressed (more or less parallel to surface) hairs . . . *s*
- s. Spikelets chiefly secund or nearly secund (all turned to the same side or position) along one side of axis of divisions of inflorescence, obliquely turned or set at an angle to the pedicel (stalk) of spikelet; perennials with scaly creeping underground rhizomes and stolons; ligule a jagged membrane about 0.5 mm. long . . . 42. *P. ANCEPS*
- s. Spikelets not turned to one side of the axis or set at an angle; annuals with a tuft of roots at base, no creeping rhizomes or stolons present; ligule a hairy fringe 1–2 mm. long . . . *t*
- t. Spikelets 3–4 mm. long . . . *u*
- u. Lower pulvini of inflorescence (the swellings at junction of lower branches of inflorescence with main axis) glabrous or minutely puberulent (with very short hairs); inflorescence usually less than $\frac{1}{2}$ as broad as long, 2–3 times as long as thick, usually long-exserted at flowering time; leaf-blades mostly erect, mainly 2–6 (rarely 7) mm. wide; most all spikelets on pedicels (stalks) several times longer than length of spikelet; spikelets long-pointed (acuminate) at tip, lanceolate . . . 34. *P. FLEXILE*

- u. Lower pulvini of inflorescence conspicuously hispid (stiffish straight hairs); inflorescence usually as broad or broader than long, less than 2 times as long as thick, the lower branches usually enclosed in the uppermost leaf-sheath at flowering time; leaf-blades mostly spreading or drooping, mainly 5–20 mm. wide (narrower in dwarfed individuals); most of spikelets on short pedicels (stalks) shorter than or barely longer than the length of spikelet; spikelets short-acuminate at tip, lance-ovoid 37b. *P. CAPILLARE* var. *occidentale*
- t. Spikelets mainly 1.5–2.6 (rarely to 3) mm. long v
- v. Main inflorescence usually $1/2$ or more the height of the plant (except in dwarfed individuals); 1st glume definitely short-pointed (acute) or V-shaped at tip; tip of spikelet (of the lemma and 2nd glume) narrowed to a long-pointed (long-acuminate) tip; spikelet lance-ovoid 37a. *P. CAPILLARE* var. *capillare*
- v. Main inflorescence usually not more than $1/3$ the height of the plant (except in dwarfed individuals); 1st glume obtuse (blunt) to somewhat short-pointed (subacute) at tip; tip of spikelet merely short-pointed; spikelet of a broader ovoid, ellipsoid, or obovoid shape . . . w
- w. At least the lower pulvini of the inflorescence (swelling at junction of lower branches of inflorescence with main axis) short hispid, rarely glabrous; spikelets mostly occurring in 2's at the ends of the branchlets; peduncle (main supporting stalk of inflorescence) $1/3$ as long as to longer than inflorescence, long-exserted 36a. *P. PHILADELPHICUM* var. *philadelphicum*
- w. At least the lower pulvini of the inflorescence glabrous, rarely with a few hairs; spikelets rather uniformly scattered throughout inflorescence on many of its branchlets, or racemosely arranged along the tips of most of the branchlets; peduncle about $1/4$ as long as the inflorescence, the base enclosed in or shortly exserted from uppermost leaf-sheath x
- x. Spikelets 0.6–0.7 mm. wide, 1.5–2 mm. long, short-stalked and somewhat racemosely arranged along tips of most of branchlets; branches of inflorescence widely spreading, the inflorescence of a broadly ovoid to deltoid shape. 36b. *P. PHILADELPHICUM* var. *tuckermani*
- x. Spikelets 0.9–1.2 mm. wide, 1.8–2.5 mm. long, on conspicuous stalks and appearing regularly scattered throughout the inflorescence; branches of inflorescence spreading to ascending, the panicle of an obovoid, oval, or ellipsoid shape . . . 35. *P. GATTINGERI*
- 1. Spikelets obtuse (blunt) or rounded at tip (very slightly pointed in *P. Bicknellii*); basal leaves of a different size and shape from those on the culm (stem), eventually becoming a winter rosette; plants blooming twice during the season, once in spring and early summer with inflorescences at the top of the culm, and later on bearing small inflorescences in the axils of the leaves, culms, or branches y
- y. Spikelets 2.9–4 mm. long, 1.5–2 mm. wide 23. *P. OLIGOSANTHES*
- y. Spikelets 1.4–2.8 mm. long, 0.7–1.2 mm. wide z
- z. Spikelets 2.3–2.9 mm. long, 1.1–1.2 mm. wide; leaves 15–20 times as long as broad. 6. *P. BICKNELLII*
- z. Spikelets 1.4–2.2 mm. long, 0.7–1 mm. wide; leaves mostly 8–12 times as long as broad . . . 1
- 1. Spikelets 1.9–2.2 mm. long 11a. *P. DICHOTOMUM* and var. *barbulatum*
- 1. Spikelets 1.4–1.8 mm. long 2
- 2. Nodes (joints) of culm (stem) glabrous; no white spots on leaf-sheaths; ligule a brush of hairs 1.5–3 mm. long 12. *P. SPRETUM*
- 2. Nodes bearded; white spots on leaf-sheaths; ligule practically lacking . . . 8. *P. MICROCARPON*
- i. Lemmas and glumes of spikelets themselves short- to long-hairy 3
- 3. Spikelets 5–6 mm. long, sharp- or slender-pointed at tip; fruit cross-wrinkled or lined; inflorescence of several or more densely-flowered racemes 32. *P. TEXANUM*
- 3. Spikelets 4.5 mm. or less long (rarely longer in *P. Boscii*), rounded or obtuse (blunt) at tip, never slender-pointed; fruit not as above; inflorescence not as above 4
- 4. Ligule a conspicuous brush of stiff white hairs 2–5 mm. long protruding at summit of leaf-sheath (look for these best developed on main cauline [stem] leaves) 5
- 5. Spikelets mostly 4–4.3 mm. long (rarely shorter), 2–2.2 mm. broad 24. *P. RAVENELII*
- 5. Spikelets 1.1–3.9 mm. long, 0.7–2 mm. broad 6
- 6. Leaf-sheaths, culms (stems) and their nodes glabrous 7
- 7. Inflorescence narrowly ellipsoid or narrowly ovoid, $1/4$ – $1/2$ as wide as long; branches of inflorescence closely ascending; many or most of the lateral spikelets equaling or longer than their pedicels (stalks) 12. *P. SPRETUM*

7. Inflorescence rhomboid (baseball-diamond-shaped) to broadly ovoid in outline, almost as wide as or as wide as long; branches of inflorescence widely spreading to ascending; most of the spikelets shorter than their pedicels. 8
8. Spikelets 1.3-2 mm. long 15a. *P. LANUGINOSUM* var. *LINDHEIMERI*
8. Spikelets 1.1-1.2 mm. long 13. *P. LONGILIGULATUM*
6. Some or all of the leaf-sheaths, culms (stems) and/or their nodes pubescent 9
9. Culms (stems), their nodes, and upper leaf-sheaths with all the hairs conspicuously long (mostly 2-6 mm. long) and horizontally spreading 10
10. Spikelets mainly 2.6-2.8 mm. (extremes 2.3-3 mm.) long; all leaf-blades or at least the lower ones covered with a soft (to the touch) dense velvety hairiness 5. *P. CONSANGUINEUM*
10. Spikelets 1.3-2.5 mm. long; leaf-blades, if hairy, not with a soft velvety type of hair 11
11. Spikelets 2-2.5 mm. long, 1.1-1.2 mm. wide 18a. *P. VILLOSISSIMUM*
11. Spikelets 1.3-2.1 mm. long, 0.8-1 mm. wide 12
12. First glume $1/6-1/3$ length of spikelet, either rounded, broadly obtuse, or subtruncate at apex. 15. *P. LANUGINOSUM*
12. First glume $1/3-1/2$ length of spikelet, elongate-triangular, more or less acutely pointed 16. *P. PRAECOCIUS*
9. Culms (stems), their nodes, and upper leaf-sheaths with shorter ascending or appressed (parallel to surface) hairs (mostly less than 2 mm. long), or, if some of the hairs spreading, then mostly less than 2 mm. long 13
13. Spikelets mainly 2.6-2.8 mm. (extremes 2.3-3 mm.) long; all leaf-blades or at least the lower ones covered with a soft (to the touch) dense velvety hairiness 5. *P. CONSANGUINEUM*
13. Spikelets 1.3-2.5 mm. long; leaf-blades hairy, but not soft velvety to the touch 14
14. Spikelets 2-2.5 mm. long, 1.1-1.2 mm. wide 18b. *P. VILLOSISSIMUM* var. *PSEUDOPUBESCENS*
14. Spikelets 1.3-2.1 mm. long, 0.8-1 mm. wide 15
15. Axis of inflorescence mostly glabrous or minutely puberulent (with short powdery-like pubescence); lower side (secondary) branches of panicle mainly simple (unbranched) 14. *P. MERIDIONALE*
15. At least the lower part of the axis of the inflorescence more or less hairy with obvious hairs, more rarely without hairs; lower side branches of panicle usually forking or branching 16
16. First glume of spikelet $1/3-1/2$ length of spikelet, as long as or longer than broad, rather acutely pointed; at least lower part of axis of inflorescence with mainly appressed pubescence (parallel to length of or pressed against axis), rarely without hairs; main leaf-sheaths of main stem usually equaling or longer than the internodes. 17. *P. SUBVILLOSUM*
16. First glume of spikelet $1/6-1/3$ (usually $1/4$) length of spikelet, angularly rounded, subtruncate, or broadly obtuse at tip, broader than long; at least lower part of axis of inflorescence with usually spreading hairs; main leaf-sheaths of main stem usually shorter than the internodes 15. *P. LANUGINOSUM*
4. Ligule either none or minute and nearly obsolete, or a brush of hairs less than 2 mm. long 17
17. Culm (stem) and leaf-sheaths covered, with a close, grayish, soft velvety (to the touch) hairiness; a hairless (glabrous) sticky band present on the culm below each bearded node; culms stout, 5 mm. or more thick 26. *P. SCOPARIUM*
17. Without the above combination of characters 18
18. Nodes (joints) of culm (stem) encircled by a conspicuous beard of spreading or down-pointing hairs (densely hairy lower sheaths or sparsely hairy nodes found in *P. latifolium* sometimes confused here) 19
19. Spikelets 3.2-5.2 mm. long, 1.8-2.2 mm. wide; leaf-blades mostly 15-40 mm. wide (rarely less) 20
20. Spikelets 3.4-3.7 (rarely 3.2) mm. long; nodes (joints) of culm (stem) with short hairs less than 2 mm. long; leaf-blades mainly $2\frac{1}{2}-5$ times as long as broad 29. *P. LATIFOLIUM*
20. Spikelets 3.7-5.2 mm. long; nodes (joints) of culm (stem) long-bearded with hairs 2 mm. or more long; leaf-blades mainly 4-7 times as long as broad 30. *P. BOSCHII*
19. Spikelets 1.5-3.3 mm. (rarely up to 3.8 mm.) long, 0.7-1.8 mm. wide; leaf-blades mainly 3-13 mm. wide 21
21. Long hairs appearing on most of the margin of the leaf-blades; leaf-blades pale green, soft, most of them in tufts crowded toward base of plant and long and narrow (linear-lanceolate to

- narrowly lanceolate); winter rosette-leaves not forming nor conspicuous; culms (stems) remaining unbranched or forking only at base 4. *P. LAXIFLORUM*
21. Without the above combination; any long marginal hairs, if present on leaf-blades, confined near base of blade; leaf-blades dull to deep green, rather uniformly scattered or crowded on stem, not crowded toward base of plant; true winter-rosette of short leaves eventually forming or present; culms eventually forking or branching from the middle or upper nodes late in the summer and fall (spring-collected specimens may not show any branching) 22
22. Spikelets 2.9–3.8 mm. long 23
23. Spikelets 1.1–1.4 mm. wide; ligule inconspicuous or obsolete; leaf-blades not velvety-hairy; culms at most with appressed hairiness; axis and branches of inflorescence glabrous or sparsely hairy, without conspicuous spreading hairiness. 7. *P. CALLIPHYLLUM*
23. Spikelets 1.5–1.8 mm. wide; ligule conspicuous, 1–1.5 mm. long; leaf-blades velvety-hairy; culms, axis, and branches of inflorescence with conspicuous spreading hairiness. 22. *P. MALACOPHYLLUM*
22. Spikelets 1.5–2.8 mm. long 24
24. All leaf-blades or at least the lower ones covered with a soft (to the touch) dense velvety hairiness; leaf-sheaths mainly hairy. 25
25. Main or largest leaf-blades averaging about 15 times as long as wide, 3–8 mm. wide, on the late summer and autumn plants 2–3 mm. wide; spikelets mainly 2.6–2.8 mm. long (extremes 2.3–3 mm.) 5. *P. CONSANGUINEUM*
25. Main or largest leaf-blades averaging about 10 times as long as wide, 7–13 mm. wide; spikelets 2–2.4 mm. (rarely 1.8 mm.) long 10. *P. ANNULUM*
24. Leaf-blades mainly glabrous, at most with some hairs on margin near base of blade; leaf-sheaths mainly glabrous. 26
26. Spikelets 0.7 mm. wide, mostly 1.5–1.8 mm. long; plants of wet habitats 8. *P. MICROCARPON*
26. Spikelets 0.9–1 mm. wide, mainly 1.8–2.2 mm. (rarely 1.7) long; plants of wet or dry habitats 27
27. Common plants of dry or rocky woods of the Ozark region; upper leaf-sheaths not dotted with pale spots; spikelets rarely with hairs, mostly glabrous; nodes of culms lightly bearded 11b. *P. DICHOTOMUM* var. *BARBULATUM*
27. Rare plant of moist gravelly ground in Carter County, southeastern Mo.; upper leaf-sheaths usually dotted with pale spots; spikelets always pubescent; nodes of culm heavily bearded 9. *P. NITIDUM*
18. Nodes (joints) of culm (stem) glabrous or with minute hairs or with hairs appressed or ascending, but not encircled by a conspicuous beard of spreading or down-pointing hairs (do not mistake sometimes densely hairy lower part of leaf-sheaths for nodes) 28
28. Most of the leaf-sheaths (but especially the upper ones) or culms mainly hairy (older specimens of *P. clandestinum* may lose main slender part of hairs but papillate stubs at base of original hairs remain on surface of sheath); the hairs may be very minute and crisp-puberulent in *P. commutatum* var. *Ashei*. 29
29. Spikelets 1.2–2 mm. long 19. *P. COLUMBIANUM*
29. Spikelets 2.5–4 mm. long 30
30. Principal leaf-blades mainly 17–35 mm. wide 28. *P. CLANDESTINUM*
30. Principal leaf-blades mainly 5–15 mm. wide 31
31. Spikelets 2.1–2.7 mm. long; pubescence of culms or leaf-sheaths minute (crisp-puberulent) 27b. *P. COMMUTATUM* var. *ASHEI*
31. Spikelets 2.9–4 mm. long; pubescence of culms or leaf-sheaths of easily seen hairs 32
32. 1st glume $\frac{1}{2}$ or more the length of the spikelet, narrowly ovate; spikelets long-hairy with hairs up to 1 mm. long; leaf-blades thin, often with papillose-hispid hairs above and below; ligule practically obsolete, less than 0.5 mm. long. 25. *P. LEIBERGII*
32. 1st glume less than $\frac{1}{2}$ the length of the spikelet, broadly ovate; spikelets glabrous to short-hairy; leaf-blades thick and firm, glabrous or sparsely hairy above, glabrous or finely hairy with usually short appressed hairs below; ligule mostly a brush of hairs 1–1.5 mm. long 23. *P. OLIGOSANTHES*
28. Most of the leaf-sheaths, but especially the upper ones, glabrous (except for hairs which may be on the margins). 33
33. Spikelets 1.5–1.8 mm. long 34

- 34. Uppermost main leaf-blade of culm 3–15 mm. (mainly 5–10) wide, 2–11 cm. (mainly 4–9) long; main leaf-blades of the culm more or less of the same or similar size. 20. *P. SPHAEROCARPUM*
- 34. Uppermost main leaf-blade of culm 10–30 mm. (mainly 15–25) wide, 8–20 cm. (mainly 10–15) long; upper 3 leaf-blades of the culm obviously longer than the ones below 21. *P. POLYANTHES*
- 33. Spikelets 1.9–3.7 mm. long 35
- 35. Leaves mainly 15–40 mm. (averaging 20–30) wide; spikelets mostly 3.4–3.7 mm. long (rarely shorter), 1.8–2 mm. wide; ligule about 1 mm. long 29. *P. LATIFOLIUM*
- 35. Leaves 4–25 mm. wide; spikelets 1.9–3.2 long, 0.9–1.3 mm. wide; ligule practically obsolete or absent 36
- 36. Main leaves with a base heart-shaped or somewhat clasping the stem (subamplexicaul), broadly lanceolate, much broader near the base 27a. *P. COMMUTATUM*
- 36. Main leaves long and narrow, linear or lanceolate, not much, if at all, broader at the base, the base not heart-shaped nor somewhat clasping the stem 37
- 37. Spikelets 1.9–2.2 mm. long, 0.9–1 mm. wide; late summer and autumn stage tree-like in habit, much-branched above middle with numerous narrow leaves often only 3–4 mm. wide and no or few leaves in lower half of plant 11a. *P. DICHOTOMUM*
- 37. Spikelets 2.3–3.2 (rarely to 3.8) mm. long, 1.1–1.6 mm. wide; late summer and autumn stage with culms less or slightly branching and leaf-blades not much different from earlier spring stage, sometimes becoming bushy-crowned above the middle 38
- 38. Main leaf-blades 4–8 mm. wide, about 15 times as long as wide; spikelets 2.3–2.8 mm. long 6. *P. BICKNELLII*
- 38. Main leaf-blades 9–15 mm. wide, about 10 times as long as wide; spikelets 2.9–3.2 mm. long 7. *P. CALLIPHYLLUM*

1. ***Panicum depauperatum* Muhl. var. depauperatum** Map 296
Flowers May–August (vernal); July–October (autumnal).
Occurs in prairies, glades, sterile open upland woods, open waste ground, and along roadsides, in the eastern half and southern third of the state west to Sullivan, Linn, Pettis, and Barton counties. Absent from the southeastern lowland counties.
Ranges from South Carolina and Georgia to Texas, north to Quebec, Ontario, and Minnesota.
The more northern var. *psilophyllum* Fern., with glabrous or sparsely pilose leaf-sheaths, has not been found in the state.

2. ***Panicum perlongum* Nash** Map 297
Flowers May–August (vernal); July–October (au-

tumnal). Occurs in prairies, glades, prairie openings of upland woods, usually in acid soils associated with chert, sandstone, or granite. Throughout most of the state, except apparently absent in the southeastern lowlands and extreme northwestern counties.
Ranges from Michigan to Manitoba, south to Indiana, Illinois, Arkansas, and Texas.
The spikelets are intermediate in length between those of *P. depauperatum* and *P. linearifolium*, and, in fact, the length of spikelet measurements overlaps with that of *P. linearifolium*, which it closely resembles. Some authors have attempted to separate *P. perlongum* from *P. linearifolium* on the basis of pedicel length, with the pedicel given as shorter than the spikelets in *P. perlongum* and longer than the spikelets in *P. linearifolium*. This character does not hold at all in Missouri material, where most of the pedicels in both species are

301 *Panicum Bicknellii*302 *Panicum calliphyllum*303 *Panicum microcarpon*

much longer than the spikelets; nor can these two species be separated on the length of the ligule.

3a. ***Panicum linearifolium*** Scribn. var.

linearifolium

Map 298

Flowers May–July (vernal); July–October (autumnal).

Occurs in prairies, rocky glades, open places along roads, and open woods in usually acid soils. Throughout the Ozarks and Ozark border region; absent from the southeastern lowlands, northwestern, west-central, and extreme northern counties.

Ranges from Georgia to Texas, north to Quebec, Ontario, Michigan, Wisconsin, and Minnesota.

3b. ***Panicum linearifolium*** var. **Wernerii** (Scribn.)

Fern.

Map 298

In similar habitats to var. *linearifolium*, but most frequent in rocky open woodland in acid soils associated with sandstone, chert, or granite. Limited to the Ozark region, north to Lincoln, Montgomery, Morgan, and Jasper counties.

Ranges from Quebec to Minnesota, south to Virginia, Kentucky, Arkansas, and Texas.

This variety with mainly glabrous leaf-sheaths is usually readily distinguishable where encountered in Missouri.

Most of the spikelets of *P. linearifolium* range in length from 2–2.7 mm. long, but specimens up to 3 mm. long occur, thus intergrading into the minimum spikelet length of *P. perlongum*. The spikelets of *P. linearifolium* are always narrower, however. The panicle of *P. perlongum* is usually much narrower relatively than that of *P. linearifolium*, averaging usually 1/6–1/3 as broad as long, whereas in *P. linearifolium* it averages 1/2–3/4 as broad as long, but there are also intergrading forms. Usually the spikelets are more closely appressed to the main axis of the panicle in *P. perlongum* than in *P. linearifolium*, with more erect appressed simple branches.

4. ***Panicum laxiflorum*** Lam.

Map 299

Panicum xalapense HBK. [P & S]

Flowers April–July (vernal); June–September (autumnal).

Occurs in low or upland woodland, and wet rocky or sandy banks, usually in acid soils associated with sandstone, chert, or granite. Eastern and southern Ozark region, north to St. Louis, Warren, and Boone counties, west to Osage, Maries, Texas, Christian, and McDonald counties.

Ranges from Maryland to Indiana, southern Illinois, Missouri, and Oklahoma, south to Florida, and Texas, Mexico, Central America, and the West Indies.

This species is easily recognized by the leaf-blades, which are pale green, soft, elongated, ciliate-margined, and mostly crowded toward the base, forming loose clumps. Sterile tufts of these long, narrow, hairy blades are frequently encountered in oak-hickory and pine-oak woodland and are readily identifiable.

5. ***Panicum consanguineum*** Kunth

See excluded species.

6. ***Panicum Bicknellii*** Nash

Map 301

Panicum Bicknellii var. *Bicknellii* [BB]

Flowers May–July (vernal); July–September (autumnal).

Occurs in dry rocky oak-hickory or pine-oak woodland in acid soils associated with chert, sandstone, or granite, more rarely in prairie openings or prairies. Infrequent in the southern Ozark region of Missouri, and locally north in Gasconade and Bates counties.

Ranges from Quebec to Michigan, south to Georgia and Missouri.

This well-marked species has narrow, long-pointed, tapering leaf-blades which become gradually narrowed at the base. The spikelets vary from somewhat pubescent to rarely glabrous.

304 *Panicum nitidum*305 *Panicum annuum*306 • *Panicum dichotomum* var. *dichotomum*
□ *Panicum dichotomum* var. *barbatulum*

7. ***Panicum calliphyllum* Ashe** Map 302
Panicum Bicknellii var. *calliphyllum* (Ashe) Gl. [BB]
 Flowers June–July (vernal); July–September (autumnal).

Occurs in oak-hickory and pine-oak woodland, where known from two isolated localities in the Ozarks, in Callaway (*Steyermark 65453*) and Ripley (upper cherty slopes along Current River, 7 mi. northwest of Doniphan, October 19, 1936, *Steyermark 20507*) counties. The specimen cited from Callaway County has spikelets up to 3.8 mm. long. It may possibly be an atypical *P. oligosanthes* having very narrow spikelets.

Ranges from Maine to Ontario, south to Connecticut, Pennsylvania, Ohio, Michigan, and Missouri.

8. ***Panicum microcarpon* Muhl.** Map 303
Panicum nitidum Lam. var. *ramulosum* Torr. [BB]
 Flowers May–September (vernal); July–October (autumnal).

Occurs in low wet woodland, margins of small streams and spring branches and low moist open ground, in the eastern quarter of the state south of the Missouri River, and locally in Barry and McDonald counties, southwestern Missouri. In the eastern sector of its Missouri range it inhabits small wooded streams and spring branches, often in sandy soil, in the Ozarks, and in wet woodlands and swampy ground of the southeastern lowland.

Ranges from Florida to Texas, north to Massachusetts, New York, Ohio, Michigan, Illinois, Missouri, and Oklahoma.

The spikelets are generally glabrous, rarely puberulent. In the autumnal stage the plants become conspicuously branched and sprawling, forming dense masses. The thin leaf-blades are usually glabrous, rarely pubescent.

9. ***Panicum nitidum* Lam.** Map 304
Panicum nitidum var. *nitidum* [BB]

Flowers May–June (vernal); July–October (autumnal).

Known only from Carter County, southeastern Missouri (gravelly ground, June 6, 1893, *Eggert 288*). This collection is in the United States National Museum, and is cited by Hitchcock and Chase (Contr. U. S. Nat. Herb. 15: 184. 1910).

Ranges from Florida to Texas, locally north to Virginia and southeast Missouri; also in the West Indies, Mexico, and Guatemala.

10. ***Panicum annuum* Ashe** Map 305
Panicum annuum var. *annuum* [BB]
 Flowers late May–August (vernal); July–October (autumnal).

Known only from Carter County, southeastern Missouri (woods near Hunter, June 6, 1893, *Eggert*).

Ranges from Georgia to Mississippi, north locally to Massachusetts, New Jersey, Pennsylvania, Tennessee, and southeastern Missouri.

- 11a. ***Panicum dichotomum* L. var. *dichotomum*** Map 306

Panicum dichotomum L. [G, BB in part, P & S]

Flowers May–July (vernal); June–November (autumnal).

Usually in dry, rocky open oak-hickory or pine-oak woodlands, on ridges or slopes of ravines in acid soils associated with sandstone, chert, or granite, less frequently in low rich woodlands. Common throughout the Ozark section, but confined to it.

Ranges from New Brunswick and Maine to Ontario, Michigan, Illinois, and Missouri, south to Florida and Texas.

- 11b. ***Panicum dichotomum* var. *barbatulum***
 (Michx.) Wood Map 306
Panicum barbatulum [P & S]
Panicum dichotomum in part [BB]

307 *Panicum longiligulatum*308 x *Panicum lanuginosum* var. *Lindheimeri*
308 • *Panicum lanuginosum* var. *fasciculatum*
308 □ *Panicum lanuginosum* var. *implicatum*309 *Panicum praeocius*

Occurs in the same situations as var. *dichotomum* with similar range in the Ozark section.

Ranges from Georgia to Texas, north to Massachusetts, New York, Ohio, Michigan, Illinois, and Missouri.

Panicum dichotomum var. *dichotomum* typically has beardless nodes of the culms and, at maturity, the fruit is usually shorter than the 2nd glume and sterile lemma, as contrasted to *P. dichotomum* var. *barbulatum* in which the nodes (usually the lower) of the culm are bearded and, at maturity, the fruit is usually covered by the longer 2nd glume and sterile lemma.

Frequent intergradation is found, however, plants occurring with the lower nodes bearded but with the fruit not covered, or with the lower nodes beardless and the fruit covered. It is questionable whether the two varieties can be maintained or will have to be united under *P. dichotomum*, as some authors have done.

The treelike branched appearance with very slender culms and narrow leaves of the autumnal phase is characteristic of these two varieties.

12. ***Panicum spretum* Schultes**

See excluded species.

13. ***Panicum longiligulatum* Nash** Map 307
Panicum lanuginosum var. *Lindheimeri* in part [BB]
Flowers May–September (vernal); June–October (autumnal).

Known from one collection from Newton County, southwestern Missouri (open banks of an artificial

pond, along highway 86, about 7 mi. east of Neosho, August 2, 1956, *Palmer 63506*).

Ranges from the West Indies and Central America (British Honduras), north to Florida and Louisiana, locally north to Missouri, Tennessee, and southeastern Pennsylvania.

It is doubtful whether this species can be maintained as distinct from *P. lanuginosum* var. *Lindheimeri* (Nash) Fern. The species is included for Missouri in the present treatment only on the basis of the identification made at the United States National Museum. Palmer's specimen is not typical, however, as most of the spikelets examined in his collection measure as much as 1.5 mm. long, thus placing it in *P. lanuginosum* var. *Lindheimeri* (as treated by Fernald and others).

14. ***Panicum meridionale* Ashe**

See excluded species.

15. ***Panicum lanuginosum* Ell.** Map 308
Flowers May–September (vernal); June–November (autumnal).

Missouri material is placed here under the following categories:

- a. Axis of inflorescence mainly glabrous or at most with a few appressed hairs; leaf-blades mainly glabrous; upper leaf-sheaths mainly glabrous, sometimes sparsely hairy . . .

15a. *P. LANUGINOSUM* var. *LINDHEIMERI*

- a. Axis of inflorescence, or at least the lowest part of it, pubescent with spreading hairs;

Plate no. 57. 1. *Panicum microcarpon*; a. Plant, $\times \frac{3}{4}$; b. Floret, $\times \frac{7}{12}$; c, d. Two views of spikelet, $\times \frac{7}{12}$. 2. *Panicum consanguineum*; a. leaf-blades hairy or glabrous (without hairs);
upper leaf-sheaths mainly hairy b

b. Hairs none or up to 2.9 mm. long on upper
surface of leaf-blades; spikelets usually
1.6–2.1 mm. long 15c. *P. LANUGINOSUM*
var. *FASCICULATUM*

b. Hairs mainly 3–6 mm. long on upper sur-
face of leaf-blades; spikelets usually 1.3–
1.5 mm. long. 15b. *P. LANUGINOSUM*
var. *IMPLICATUM*

15a. ***Panicum lanuginosum* var. *Lindheimeri***

(Nash) Fern. Map 308

Panicum Lindheimeri Nash [Hitchcock, Fassett]

Panicum lanuginosum var. *septentrionale* Fern. [P & S]

Usually frequents moist ground, either along
margins of streams and spring branches, moist lime-
stone and sandstone bluffs and ledges, and limestone
glades, or wet meadows and prairie swales; occasion-
ally along railroads. Mainly in the eastern and south-
ern half of the state; not recorded from the north-
western third of the state.

Ranges from Nova Scotia and New Brunswick to
Manitoba and Minnesota, south to Florida, and
Texas; also Arizona and California.

This variety is most often found in wet ground of
low meadows and prairie swales or moist limestone
rocks along streams, where it may frequent the ledges
or the limestone glades above the stream.

15b. ***Panicum lanuginosum* var. *implicatum***

(Scribn.) Fern. Map 308

Panicum implicatum Scribn. [Hitchcock, Fassett]

Occurs in dry rocky woodland, often on cherty or
sandstone slopes, sandy alluvial soils in valleys, less
frequently in prairie openings or along railroads.
Mostly found in the Ozark section and locally north-
ward in the state; apparently absent from the south-
eastern lowland and extreme northwest sectors.

Ranges from Newfoundland to Ontario and
Minnesota, south to District of Columbia, Pennsyl-
vania, Ohio, Indiana, Illinois, and Missouri.

This is the least frequently encountered of the
three varieties here treated.

A number of specimens labeled var. *implicatum*
possess spikelets more than 1.5 mm. long and fall in
the range of var. *fasciculatum*. Such specimens combine
the characters of both varieties, making it arbitrary
as to which name they should take.

15c. ***Panicum lanuginosum* var. *fasciculatum***

(Torr.) Fern. Map 308

Panicum lanuginosum var. *tennesseense* (Ashe) Gl. [BB]

Panicum implicatum in part [Fassett], not Scribn.

Panicum tennesseense Ashe [Hitchcock]

Panicum huachucae Ashe [Hitchcock]

Occurs in many types of habitats throughout the
state, where found on prairies, limestone or other
rocky substrata and glades, rocky slopes along streams,
ravines, small valleys, dry open woods, meadows,
pastures, waste ground, and along railroads. Common
throughout Missouri, and the commonest variation
encountered.

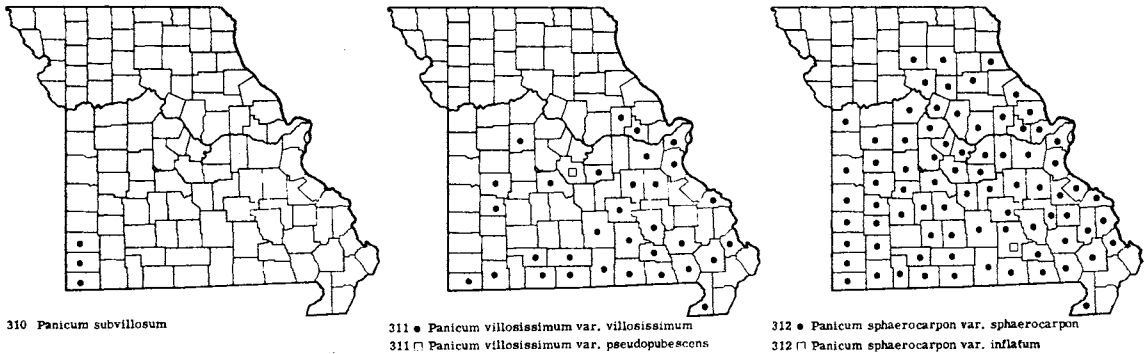

Ranges from Newfoundland to Quebec, Ontario,
Minnesota, South Dakota, Montana, Idaho, and
British Columbia, south to Florida and California.

As may be judged by the synonymy under each of
the above varieties, there is at present no agreement
among botanists as to the splitting up of the *Panicum*
lanuginosum–*P. Lindheimeri* complex. What the future
consensus of botanical opinion will be with respect
to this group is very uncertain. Some authors (Fassett
and others) maintain as distinct species *P. Lindheimeri*
for plants having leaf-sheaths glabrous or nearly so
(including both *P. lanuginosum* var. *Lindheimeri* and
var. *septentrionale*) and *P. implicatum* for those with
hairy leaf-sheaths (including here *P. lanuginosum* var.
fasciculatum and var. *implicatum*, *P. huachucae*, and *P.*
tennesseense). Though this procedure has its merits, to
follow it would indicate little or no overlapping be-
tween *P. implicatum* and *P. Lindheimeri*. This is not the
case, however; although the two are quite distinct as
extremes, there are too many intergradations in the
range and degree of pubescence of leaf-blades and
leaf-sheaths. For the same reason, it seems impossible
to maintain as distinct species those plants previously
named *Panicum tennesseense*, *P. huachucae*, *P. implicatum*,
and *P. Lindheimeri*.

The other method of treating the above entities as
varieties within one group (*P. lanuginosum*) is the
procedure followed by Fernald and by Gleason, and
to a lesser extent in the present flora. Gleason (*New*
Ill. Fl. 1: 221. 1952) has mainly followed Fernald's
treatment in the eighth edition of *Gray's Manual* (p. 215),
but has divided the group to a greater extent than has
Fernald, emphasizing papillose and nonpapillose types
of hairs.

In the present treatment, *P. lanuginosum* var. *septen-*
trionale, which has been segregated from var. *Lind-*
heimeri on the basis of the larger spikelets (1.6–2 mm.
instead of 1.3–1.6 mm. long), is placed under *P. lanu-*
ginosum var. *Lindheimeri* as one inclusive variety with
spikelets varying from 1.3–2 mm. in length, whereas
variations with both types of papillose and nonpapil-
lose hairs are included under var. *fasciculatum*.

The majority of specimens encountered in Mis-
souri can be placed satisfactorily in one of the three

varieties treated in the present flora. However, an occasional one offers perplexities. An example is *Palmer 65623* (upland prairie, 4½ mi. northwest of Diamond, Newton Co., June 17, 1957) with spikelets only 1.3–1.5 mm. long, but with a dense ascending pubescence of leaf-sheaths, and both short to long hairs on upper surface of the leaf blades. While showing some characteristics of *P. lanuginosum* var. *lanuginosum*, the short spikelets and occasional long hairs (over 3 mm. long) on the upper leaf surface indicate a closer relationship with var. *implicatum*.

16. ***Panicum praecocius* Hitchc. & Chase** Map 309
Flowers May–July (vernal); June–September (autumnal).

Occurs in dry open woods, prairies, glades, and thickets. Widespread in Missouri.

Ranges from Ontario and Michigan to Minnesota and Nebraska, south to Illinois, Missouri, and Texas.

This species resembles *P. lanuginosum* var. *implicatum* and *P. subvillosum* in having the hairs on the upper surface of the leaf-blades mostly 3–6 mm. long. From the former it differs in the longer spikelets and longer, more acutely pointed first glume, and from the latter in the longer, more widely spreading hairs on the leaf-sheaths and on most of the culms.

The culms of this species often branch before the expansion of the first main panicle and develop a geniculate habit (bent abruptly at the nodes of the culm) as contrasted with *P. subvillosum* and *P. lanuginosum* var. *implicatum*.

17. ***Panicum subvillosum* Ashe** Map 310
Flowers May–August (vernal); July–November (autumnal).

Occurs mainly in dry rocky woods. Known only from southwestern Missouri, in Jasper, Newton, and McDonald (Noel, May 26, 1909, *Bush 5741*, *5741A*, and *5741B*) counties.

Ranges from Nova Scotia to Saskatchewan, south to Massachusetts, New York, Pennsylvania, northern Indiana, and Missouri.

Bush's specimens were identified as *P. meridionale* Ashe by Gleason and form the basis for the inclusion of that species from Missouri in the *New Britton and Brown Illustrated Flora* (for which see under excluded species, p. 232).

18a. ***Panicum villosissimum* Nash var. villosissimum** Map 311
Flowers May–July (vernal); June–October (autumnal).

Occurs mainly in dry open or rocky thin oak-pine or oak-hickory woodland on acid soils associated with sandstone, chert, or granite, throughout the Ozark section north to St. Louis, Montgomery, Pettis, and St. Clair counties.

Ranges from Central America to eastern Mexico, and from Florida to Texas north to Massachusetts, New York, Ontario, Michigan, Wisconsin, and Minnesota.

Of the various species of panicum found in Missouri, *P. villosissimum* var. *villosissimum* is probably the one most conspicuously hairy by virtue of the abundant long spreading hairs of the culms, nodes, leaf-sheaths, and leaf-blades. In the long spreading hairs of the culms and leaf-sheaths, it resembles *P. praecocius* and *P. lanuginosum* var. *implicatum*, but has longer spikelets than those species, and generally broader leaf-blades (5–13 mm. wide) than *P. praecocius* (4–6 mm.). The hairs on the upper leaf surface of *P. villosissimum* are usually elongated, varying from usually 2–3 mm. up to 5 mm. long.

18b. ***Panicum villosissimum* var. pseudopubescens** (Nash) Fern. Map 311
Flowers May–July (vernal); June–October (autumnal).

Known only from Miller County (cherty upland

woods of ravine, tributary to Grand Glaize branch of Lake of the Ozarks, 3 mi. southwest of Brumley, Oct. 25, 1936, *Steyermark 20685*).

Ranges from Guatemala and Florida to Texas, north to Connecticut, New York, Ohio, Michigan, Wisconsin, and Minnesota.

The Missouri specimen was determined by Mrs. Chase, who judged it to be abnormal or not characteristic. Of this specimen she wrote (letter of May 27, 1937) that it 'looks as if it were a combination of late autumnal phase with a precocious winter rosette, well grown as it is in early spring. I have seen specimens of this kind in ground that has been burned over where the plant seems to produce vernal and autumnal phase at the same time.'

Possibly, a re-collection from this locality may show that the plant will have to be referred instead to var. *villosissimum*. Until such time as a verification of the species from another collection at the Miller County station or from another locality is forthcoming, the variety is being maintained tentatively for the state.

19. ***Panicum columbianum*** Scribn.

See excluded species.

20. ***Panicum sphaerocarpon*** Ell. Map 312

Flowers May–September (vernal); July–November (autumnal).

Occurs most frequently in dry or rocky open ridges or slopes in oak-hickory or pine-oak woodland in acid soils associated with sandstone, chert, or granite substrata, also on sandstone, chert, or granite glades, acid-soil prairies, and alluvial or moist ground along streams. Throughout the Ozark region and central Missouri north to Marion, Macon, Linn, Saline, and Jackson counties.

Missouri material falls into two varieties:

Common type; spikelets 1.5–1.8 mm. long; ligule obsolete or not evident; leaf-sheaths lacking viscous (sticky) spots . . . 20a. **P. SPHAEROCARPON**

var. **SPHAEROCARPON**

Rare, known from Shannon Co.; spikelets 1.3–1.5 mm. long; ligule evident, 0.3–1 mm. long;

upper leaf-sheaths sometimes with viscous spots.

20b. **P. SPHAEROCARPON** var. **INFLATUM**

20a. ***Panicum sphaerocarpon*** var. **sphaerocarpon** Map 312

Panicum sphaerocarpon Ell. [G, P & S]

The common variety occurring in Missouri.

Ranges from Vermont and Ontario to Michigan, southern Illinois, Missouri, and Kansas, south to Florida, Texas, eastern Mexico, Central America, and northern South America.

20b. ***Panicum sphaerocarpon*** var. **inflatum**

(Scribn. & Sm.) Hitchc.

Map 312

Known only from Shannon County in southeastern Missouri (Monteer, *Bush 753*, and *Bush 747* in part).

Ranges from Florida to Texas, north to Delaware and southeastern Missouri.

21. ***Panicum polyanthes*** Schult.

Map 313

Flowers May–August (vernal); July–November (autumnal).

Occurs along sandy and moist banks of small streams, low wet woods, moist sandstone ledges, and occasionally in wet prairie swales, generally in acid soils in the southeastern half of the state north to Lincoln and Boone counties, west to Phelps and Howell counties, and locally to Johnson County.

Ranges from Florida to Texas north to Massachusetts, Pennsylvania, Ohio, Michigan, Indiana, Illinois, Missouri, and Oklahoma.

Although very similar to *P. sphaerocarpon*, this species is usually readily separated from *P. sphaerocarpon* by the relatively longer and broader, thinner leaf-blades, which are more numerous nerved (41–115–instead of 25–67–nerved), the conspicuously smaller reduced lower leaf-blades as contrasted with the uppermost ones, and the relatively longer than broad as well as longer panicles. In general, *P. polyanthes* is found in lower wetter sites than *P. sphaerocarpon*, the latter mostly frequenting dry rocky upland open woods or rocky open situations.

PLATE NO. 58

313 *Panicum polyanthes*

314 *Panicum malacophyllum*

315 • *Panicum oligosanthos* var. *oligosanthos*
 315 □ *Panicum oligosanthos* var. *Helleri*
 315 x *Panicum oligosanthos* var. *Scribnerianum*

22. ***Panicum malacophyllum* Nash** Map 314
 Flowers late May–July (vernal); July–September (autumnal).

Occurs usually in dry sandy or rocky open upland woods, less frequently in sandy openings or along hedge rows. Most common in southwestern Missouri, locally east to Shannon and New Madrid counties, and locally northwest to Johnson County (sandy open woods, Warrensburg, July 4, 1903, *Stigall 8*).

Ranges from Tennessee, Missouri, and Kansas, south to Arkansas, Oklahoma, and Texas.

A very distinct species, possessing a soft velvety pubescence, most conspicuous on the leaf-blades and culms, but also soft pubescent on the spikelets and to a lesser extent on the leaf-sheaths.

23. ***Panicum oligosanthos* Schultes** Map 315
 Flowers May–July (vernal); June–November (autumnal).

Missouri material falls into the following categories:

- a. Leaf-sheaths of main leaves with appressed pubescence (lying along and close against surface); spikelets 3.5–4 mm. long, on pedicels (stalks) often 5–15 mm. long. 23a. *P. OLIGOSANTHES* var. *OLIGOSANTHES*
- a. Leaf-sheaths of main leaves glabrous or with hairs spreading away from surface; spikelets 2.8–3.9 mm. long, on pedicels mostly less than 5 mm. long b
- b. Spikelets mostly 2.8–3.1 mm. long 23b. *P. OLIGOSANTHES* var. *HELLERI*
- b. Spikelets mostly 3.2–3.6 mm. (rarely 3.9 mm.) long 23c. *P. OLIGOSANTHES* var. *SCRIBNERIANUM*

- 23a. ***Panicum oligosanthos* var. *oligosanthos***
Panicum oligosanthos Schultes [G]

Map 315

Occurs in sandy open ground, wooded sandstone

or limestone slopes, and wooded rocky slopes along streams, usually in acid soils. Scattered in the southern third of the state north to Phelps (*Steyermark 20901*) and east to Scott (*Steyermark 20749*) county.

Ranges from Florida to Texas, north to New Jersey, Indiana, Illinois, Missouri, and Oklahoma.

- 23b. ***Panicum oligosanthos* var. *Helleri***
 (Nash) Fern. Map 315

Occurs in rocky open woods, prairies, glades, open ground, and along railroad tracks. Frequent in the southwestern quarter of the state, rare and local east to St. Louis County and north to Grundy and Worth counties.

Ranges from Missouri to Louisiana, Oklahoma, Texas, and New Mexico.

- 23c. ***Panicum oligosanthos* var. *Scribnerianum***
 (Nash) Fern. Map 315

Occupies a variety of habitats in dry open or upland rocky or sandy woods, glades, prairies, rocky banks of streams, sandy open or waste ground, and along railroads. Common throughout Missouri, and expected to be found in every county. One of the commonest and most frequently encountered *Panicum* in Missouri.

Ranges from Maine to British Columbia, south to Virginia, Georgia, Tennessee, Arkansas, Texas, Arizona, and California.

The spikelets of *P. oligosanthos* have a characteristic turgid obovate shape with 7–9 strong nerves. In the autumnal state the branches are more or less crowded and top-heavy toward the summit with rather firm elongated leaf-blades, which are not reduced in size.

Where *P. oligosanthos* var. *Scribnerianum* occurs in grazing areas, it is considered to be one of the most important of the secondary grasses for green forage palatability and nutrition.

The var. *Scribnerianum* and var. *Helleri* have leaf-

316 *Panicum Ravenelii*

317 *Panicum Leibergii*

318 *Panicum scoparium*

sheaths, leaf-blades, and culms varying from pubescent to glabrous; the spikelets also vary from sparsely hairy to glabrous. The hairs on the leaf-sheaths of var. *Scribnerianum* and var. *Helleri* are often papillose-hirsute. The varieties intergrade into one another, and various intermediates between the named varieties are difficult to place. Some specimens, such as *Palmer 65943* (sandy open woods along Horse Creek, 1 mi. east of Milford, Barton County, July 6, 1957) have spikelets nearly 4 mm. long on pedicels 5–15 mm. long characteristic of *P. oligosanthos* var. *oligosanthos*, but with spreading pubescence on leaf-sheaths characteristic of var. *Scribnerianum*.

24. ***Panicum Ravenelii*** Scribn. & Merr. Map 316
Flowers May–July (vernal); June–October (autumnal).

Occurs on dry or rocky open ravine slopes and ridges in pine-oak or oak-hickory upland woodland, open rocky sterile fields, in acid soils associated with sandstone, chert, or granite substrata, rarely on limestone glades. Scattered in the Ozark region, mainly in the southern section of it, extending north to Cedar, Phelps, Gasconade, Washington, and Ste. Genevieve counties.

Ranges from Florida to Texas, north to Delaware, Maryland, Kentucky, Missouri, and Oklahoma.

This species is characterized by its generally purplish, rather stout culms covered with long appressed-ascending hairs, the thick, dull or olive green, lanceolate leaf-blades, the prominent ligule, and the relatively large pubescent spikelets.

25. ***Panicum Leibergii*** (Vasey) Scribn. Map 317
Flowers May–August (vernal); June–September (autumnal).

Occurs in rocky or open woods, alluvial or bottom meadows, and prairies. Rare and scattered over the state.

Ranges from New York to Saskatchewan, south to Pennsylvania, Ohio, Indiana, Illinois, and Kansas.

An infrequently collected species, but easily recognized by the combination of rather thin, narrowly lanceolate pubescent leaf-blades, conspicuously hairy leaf-sheaths with spreading papillose-hispid hairs, practically no ligule, relatively large spikelets with long spreading hairs up to 1 mm. long, and the relatively long lance-ovate, acutish 1st glume which reaches half the length of the spikelet.

26. ***Panicum scoparium*** Lam. Map 318
Flowers June–August (vernal); July–November (autumnal).

Occurs most commonly in sandy open prairies and prairie swales, sandstone exposures, sandy open woods, sandy roadsides, and along railroads. Scattered mainly in the southern third of the state, most frequent in the unglaciated prairie section, absent from most of the Ozark counties.

Ranges from Florida to Texas, north to Massachusetts, New York, Kentucky, Missouri, and Oklahoma.

This is one of the taller species of *Panicum* in Missouri, attaining a height of nearly 1.5 meters. In the autumnal state, the culms fork and branch with many crowded smaller branchlets bearing leaves smaller in size than those of the main stem. With its dense velvety pubescence covering the leaf-blades, leaf-sheaths, and stout culms, together with the conspicuous glabrous band below the bearded nodes, one is not likely to confuse *P. scoparium* with any other species of *Panicum*.

- 27a. ***Panicum commutatum*** Schultes var. ***commutatum*** Map 319
Panicum commutatum Schultes [G, P & S]
Flowers May–August (vernal); June–November (autumnal).

Occurs in alluvial rich woods and thickets, in the southeastern lowland section, and elsewhere on dry wooded sandstone or chert slopes and wooded banks of streams.

319 • *Panicum commutatum* var. *commutatum*
319 □ *Panicum commutatum* var. *Ashei*

320 *Panicum clandestinum*

321 *Panicum latifolium*

Found only in southern Missouri northeast to Ste. Genevieve County, west to McDonald County, most frequent in the southeastern corner of the state, where frequent on Crowley Ridge and in the southeastern lowland section.

Ranges from Florida to Texas, north to Massachusetts, New York, Ohio, Michigan, Illinois, and Missouri.

27b. *Panicum commutatum* var. *Ashei*

(Pearson) Fern.

Map 319

Flowers May–July (vernal); July–November (autumnal).

Frequents slopes, crests, ridges, and ravines in dry rocky pine-oak or oak-hickory woodland in acid soils associated with sandstone, chert, or granite substrata, and also along rocky banks of streams. Restricted to the Ozark region of Missouri, extending north to Gasconade County, west to Laclede, Christian, and McDonald counties.

Ranges from Massachusetts to Michigan, Indiana, and Missouri, south to Florida, Mississippi, Arkansas, and Oklahoma.

The variety *Ashei* is distinguished from *P. commutatum* mainly by the minute puberulence covering the culms and leaf-sheaths, the narrower leaf-blades 5–11 mm. instead of 10–25 mm. wide, and the more slender wiry culms. The culms are dull purplish in both varieties, but in var. *Ashei* the leaf-blades are generally flushed with purple, whereas in var. *commutatum* they usually remain a deep green shade. The spikelets average somewhat larger in var. *commutatum* (2.2–3.2 mm. long, as compared with 2.1–2.7 mm. in var. *Ashei*).

28. *Panicum clandestinum* L.

Map 320

Flowers May–September (vernal); July–November (autumnal).

Frequents moist thickets in valleys, along streams, roadsides, alluvial ground, prairie swales, open upland woods, and along railroads. Common throughout Missouri; one of the commonest species in the state.

Ranges from Quebec and Nova Scotia to Maine, Michigan, Iowa, and Kansas, south to Florida and Texas.

The papillose-hispid leaf-sheaths distinguish this species from both *P. latifolium* and *P. Boscii* with which it is sometimes confused, but especially with *P. latifolium*. Even in those specimens in which most of the hair has fallen, the papillate bases of at least the lower leaf-sheaths usually remain to indicate their presence; sometimes the upper leaf-sheaths are glabrous except for the ciliate margins.

The spikelets vary in size from 2.5–3.2 mm. long. The broadly lanceolate leaf-blades vary from usually glabrous on both sides with some scabrous hairs near the tip, to rarely pubescent above and below with scabrous and ciliate margins near the base.

29. *Panicum latifolium* L.

Map 321

Flowers May–August (vernal); July–October (autumnal).

Occurs in rich or rocky woodland, on slopes of ravines and bluffs, or in wooded valleys along streams, also in upland woods and thickets. Throughout Missouri.

Ranges from Maine and Quebec to Minnesota, south to North Carolina, Tennessee, Missouri, and Kansas.

Plate no. 59. 1. *Panicum Leibergii*; a, b. Two views of spikelet, $\times 7\frac{1}{2}$; c. Floret, $\times 7\frac{1}{2}$. 2. *Panicum commutatum* var. *Ashei*; a, b. Two views of spikelet, $\times 7\frac{1}{2}$; c. Floret, $\times 7\frac{1}{2}$. 3. *Panicum clandestinum*; a, b. Two views of spikelet, $\times 7\frac{1}{2}$; c. Floret, $\times 7\frac{1}{2}$. 4. *Panicum Boscii*; a, b. Two views of spikelet, $\times 7\frac{1}{2}$; c. Floret, $\times 10$. 5. *Panicum scoparium*; a. Plant, $\times \frac{3}{4}$; b. Floret, $\times 7\frac{1}{2}$; c, d. Two views of spikelet, $\times 7\frac{1}{2}$. 6. *Panicum commutatum* var. *commutatum*; a. Plant, $\times \frac{3}{4}$; b. Floret, $\times 7\frac{1}{2}$; c, d. Two views of spikelet, $\times 7\frac{1}{2}$. 7. *Panicum latifolium*; a. Plant, $\times \frac{3}{4}$; b. Floret, $\times 7\frac{1}{2}$; c. Spikelet, $\times 7\frac{1}{2}$.

PLATE NO. 59

322 • *Panicum Boscii* var. *Boscii*
 322 □ *Panicum Boscii* var. *molle*

323 *Panicum geminatum*

324 *Panicum texanum* (Texas Millet)

This species typically has mostly glabrous culms, leaf-sheaths and leaf-blades, the latter, ciliate at base. However, these parts may show varying amounts of hairiness on some plants. Some specimens have the lower leaf-sheaths softly hairy, but the upper ones are usually glabrous, except for ciliate margins at the base. A band or ring of gray-white hairs is found at the summit of the leaf-sheath. The nodes of the culms are usually glabrous, but the lower nodes are sometimes shortly or sparsely hairy. Spikelets vary from 3.2–3.7 mm. long and 1.8–2 mm. wide.

The species is sometimes confused with the other two broadest-leaved species of *Panicum* in Missouri, *P. clandestinum* and *P. Boscii*. Especially pubescent forms of *P. latifolium* may be distinguished from *P. Boscii* by the shorter spikelets (3.2–3.7 instead of 3.7–5.2 mm. long), and by the glabrous or short-haired nodes, the nodes in *P. Boscii* being long-bearded with hairs 2 mm. or more long. A number of specimens of *P. latifolium* from northern Missouri, misidentified as *P. Boscii*, have long hairs on the lower part of the leaf-sheaths or sparsely or short-hairy nodes. An examination of such specimens reveals either the shorter spikelets or the shorter hairiness around the nodes of *P. latifolium*. Usually glabrous *P. latifolium* may be distinguished from unusual apparently glabrous forms of *P. clandestinum* by the larger spikelets (3.2–3.7 instead of 2.5–3.2 mm.), when these are present, and, vegetatively, by the leaf-sheaths and margins of leaf-blades lacking stiff papillose hairs (hairs which arise from a swelling or bump at base), the remains of which can be observed on the surface of the leaf-sheaths or the margins of the leaf-blades in glabrate *P. clandestinum*, and by the leaf-sheaths usually being much shorter than their internodes, whereas in *P. clandestinum* the leaf-sheaths nearly equal or are longer than the internodes, the upper ones often overlapping in *P. clandestinum*.

30. *Panicum Boscii* Poir.

Flowers May–July (vernal); July–October (autumnal).

Occurs in dry open, often rocky woodland in various types of topography – upland, lowland, ridge tops, ravine slopes, or bluffs.

Missouri material may be separated as two varieties:

- Leaf-blades glabrous or nearly so on lower surface; culms glabrous or sparsely or minutely hairy (puberulent) . . . 30a. *P. Boscii* var. *Boscii*
 Leaf-blades velvety hairy on lower surface; culms usually soft-hairy . . . 30b. *P. Boscii* var. *molle*

30a. *Panicum Boscii* var. *Boscii* Map 322 *Panicum Boscii* Poir. [G, P & S]

Common throughout the Ozark region and mostly confined to it.

Ranges from Massachusetts to Ohio, Illinois, and Missouri, south to Florida and Texas.

30b. *Panicum Boscii* var. *molle* (Vasey) Hitchc. & Chase Map 322

Known only in the Ozark, Crowley Ridge, and southeastern lowland sections of the state.

Ranges from Connecticut to southern Illinois and Missouri, south to Florida and Texas.

The two varieties of *P. Boscii* may always be distinguished from *P. clandestinum* and *P. latifolium*, the other very broad-leaved species in Missouri, by the long-bearded nodes of the culm with hairs 2 mm. or more long, and by the larger spikelets, usually 4–5.2 mm. (sometimes only 3.7). Specimens from northern Missouri, here referred to *P. latifolium*, sometimes have been mistaken for *P. Boscii*, but lack the truly long-bearded nodes and/or longer spikelets characteristic of *P. Boscii*. The leaves in *P. Boscii* usually are only 2½–5 times as long as broad, whereas in *P. latifolium* they are usually 4–7 times as long as broad. Some

325 *Panicum dichotomiflorum*

326 *Panicum flexile*

327 *Panicum Gattingeri*

Missouri specimens occasionally have some leaf-blades as narrow as 0.9 cm. wide, most of them, however, ranging from 1.8–3.3 cm. wide.

It is questionable whether the var. *molle* can be maintained as distinct from var. *Boscii*, as various non-correlated intergradations occur between the two (see Deam, *Grasses of Indiana*, p. 301. 1929).

31. ***Panicum geminatum*** Forsk. Map 323
Paspalidium geminatum (Forsk.) Stapf.
Flowers June–October.

Introduced along railroads, where known only from St. Louis County (right-of-way, Wabash R. R. track, north of Palm St. along the most western track, St. Louis, June 30, 1957, *Muehlenbach* 1246; same locality, September 8, 1957, *Muehlenbach* 1354).

Ranges from Florida to Texas; also Guatemala, and tropical regions of both hemispheres.

This is a mostly glabrous perennial with more or less succulent culms and rather inflated leaf-sheaths with a hairy ligule about 1 mm. long. The leaf-blades are 10–20 cm. long, 3–6 mm. wide, somewhat scabrous on the upper surface and margins. The inflorescence consists of 12–18 rather short erect or ascending racemes. No distinct winter leaf-rosettes are produced.

32. ***Panicum texanum*** Buckl. Texas Millet Map 324
Flowers July–November.

Introduced along railroads, where known only from St. Louis County (Baden freight yard of M.-K.-T. Railroad along the western siding near Dodridge Avenue, St. Louis, October 22, 1954, *Muehlenbach* 517).

Ranges from northern Mexico and Arizona to Texas and Florida, north to South Carolina, Alabama, Mississippi, Missouri, and Kansas.

This is a branching annual with culms which often root at the lower nodes. The culms below the nodes and below the inflorescence are generally softly hairy, as are the leaf-sheaths. The leaf-blades, from 8–20 cm.

long, and 7–15 mm. wide, are also softly hairy. The axis and branches of the inflorescence are pubescent.

33. ***Panicum dichotomiflorum*** Michx. Map 325
Flowers June–October.

Moist open and alluvial soils and gravel bars along streams, low fields, roadside ditches, waste and cultivated ground, rocky glades, and along railroads.

Common throughout Missouri.

Ranges from Quebec to Ontario, Minnesota, and Nebraska, south to Florida, Texas, Mexico, and the West Indies; introduced in some western states.

Of the varieties described, Missouri material would fall into both var. *dichotomiflorum* and var. *geniculatum* (Wood) Fern., which are separated as follows:

Culms straight or nearly so, erect or ascending, slender, 2–3 mm. thick; leaf-sheaths scarcely or not inflated; leaf-blades 4–10 mm. wide; main inflorescence terminal, becoming long-exserted with ascending hair-like branches; spikelets loosely arranged on the branchlets

P. DICHOTOMIFLORUM var. DICHOTOMIFLORUM

Culms crooked or strongly geniculate (zig-zag), depressed or low-spreading, stout, 3–6 mm. thick; leaf-sheaths usually conspicuously inflated; leaf-blades 6–20 mm. wide; inflorescences arising from most of the nodes, their bases included or only slightly exserted with widely spreading branches; spikelets crowded P. DICHOTOMIFLORUM

var. GENICULATUM

Although plants are found which fit these extremes, there appears to be too much intergradation and lack of correlation in the several characters enumerated in the key to justify separating the varieties as distinct.

34. ***Panicum flexile*** (Gattinger) Scribn. Map 326
Flowers July–October.

Occurs in usually sterile soils of rocky open ground, glades and exposed bluff escarpments of sandstone, chert, granite, and leached limestone, eroded and

open slopes, cherty and sandy open woods, low woods along creeks, gravel bars, prairies, and wet meadows in small valleys.

Common throughout southern and central Missouri, and extending north to Marion, Shelby, Linn, Gentry, and Holt (Big Lake State Park, *Steyermark* 15105, as to plant on left side of sheet).

Ranges from Florida to Texas, north to New York, Quebec, Ontario, Michigan, Iowa, and South Dakota.

This species is sometimes confused with *Eragrostis capillaris*, *Panicum capillare* var. *occidentale*, and *P. philadelphicum*, resembling each of them to some extent. The longer and long-pointed spikelets distinguish it from *P. philadelphicum*, the mostly glabrous lower pulvini of the inflorescence separate it from *P. capillare* var. *occidentale*, whereas the 1-flowered instead of 2-4-flowered spikelets distinguish it at once from *Eragrostis capillaris*.

35. ***Panicum Gattingeri*** Nash Map 327
Panicum capillare var. *campestre* Gatt. [BB]
 Flowers August–October.

Occurs commonly in fallow fields, especially in alluvial soils in valleys, in dry rocky ground and glades of sandstone, chert, granite, or leached limestone, gravel bars, and wet soils bordering sloughs, streams, and thickets.

Mainly found in southern and central Missouri, but extending north locally to Macon, Putnam, and Grundy counties.

Ranges from Quebec and Massachusetts to New York, Pennsylvania, Ohio, Indiana, Illinois, and Minnesota, south to North Carolina, Georgia, Tennessee, Arkansas, and Oklahoma.

Stunted or dwarfed plants often found in moist spots on glades are sometimes misidentified as *P. philadelphicum* var. *philadelphicum*. In general appearance, this species resembles and has much in common with *P. capillare*, from which it is separated by the smaller, rather oval or ellipsoid panicle, the smaller spikelets, and the generally glabrous lower pulvini of the inflorescence. The culms, axis, and branches of the inflorescence, and spikelets of *P. Gattingeri* are usually prevailing pale green or grass green, whereas in *P. capillare* var. *capillare* and var. *occidentale* the inflorescence and culms prevailing become dull lavender or magenta purple.

- 36a. ***Panicum philadelphicum*** Bernh. var.

philadelphicum Map 328

Panicum philadelphicum Bernh. [G, P & S]

Flowers June–October.

Occurs most frequently in rocky open ground, rocky open and upland woods, on sandstone, chert, granite, and limestone glades, eroded slopes, gravel bars, along streams, and fallow fields.

Essentially confined to the Ozark region of Missouri northeast into Ralls County in area believed to be unglaciated and Ozarkian in character of flora and topography.

Ranges from Georgia and Texas, north to New Hampshire, Quebec, New York, Ohio, Michigan, Indiana, Illinois, and Iowa.

- 36b. ***Panicum philadelphicum*** var. ***Tuckermanni***

(Fern.) *Steyermark* & Schmolll Map 328

Panicum Tuckermanni Fern. [G]

Panicum philadelphicum in part [BB]

Flowers July–October.

Known only from Washington County in the eastern Ozark section (alluvial gravel bar along Meramec River, vicinity of Green Cave, T40N, R1W, sect. 24 and 25, 6½–7 mi. [by air] north of Anthonies Mill, September 26, 1954, *Steyermark* 77796).

Ranges from Nova Scotia and Quebec to Minnesota, south to Virginia, Ohio, Indiana, and Missouri.

A discussion of the variation of this group and its relationships is to be found in Rhodora 41: 86–90. 1939, and in Fassett's *Grasses of Wisconsin*, p. 84. 1950. The differences between var. *philadelphicum* and var. *Tuckermanni* were brought out in the key to *Panicum*. *Panicum philadelphicum* var. *Tuckermanni* is maintained in the present treatment as a variety, instead of a species, because there is too much intergradation between it and var. *philadelphicum* as regards the glabry of the pulvini, prominence and relative exertion of the inflorescence, and number and arrangement of the spikelets in the inflorescence.

- 37a. ***Panicum capillare*** L. var. ***capillare***

Witch Grass Map 329

Panicum capillare L. [G, P & S]

Panicum capillare var. *agreste* Gatt. [BB]

Flowers July–October.

Frequents various kinds of open or sunny habitats,

Plate no. 60. 1. *Panicum dichotomiflorum*; a. Panicle, $\times \frac{3}{4}$; b, c. Two views of spikelet, $\times \frac{7}{12}$; d. Floret, $\times \frac{7}{12}$. 2. *Panicum texanum*; a. 328 □ *Panicum philadelphicum* var. *Tuckermanni*

329 • *Panicum capillare* var. *capillare* (Witch Grass)
329 □ *Panicum capillare* var. *occidentale*

330 *Panicum miliaceum* (Broomcorn Millet)

either wet or dry, occurring in cultivated, waste, and alluvial soils, gravel bars and banks of streams, limestone, sandstone, chert, and granite glades, and along railroad tracks. Throughout Missouri.

Ranges from Florida to Texas, north to Maine, Quebec, Ontario, Manitoba, and Montana; also Bermuda.

37b. *Panicum capillare* var. *occidentale*

Rydb.

Map 329

Occupies similar habitats as var. *capillare*, but less common, and mostly absent from the Ozark and unglaciated prairie sections.

Ranges from Quebec to British Columbia, south to New Jersey, West Virginia, Kentucky, Missouri, Texas, Arizona, and California.

Both these varieties are distinguished in the key to *Panicum*. At maturity both varieties become magenta- or rose-purple throughout the inflorescence and also frequently on most of the culms. When occurring in quantity, the mass rose-purplish color effect is very striking. When mature, the entire sprawling inflorescence breaks away from the rest of the plant, and becomes blown about as a 'tumbleweed.'

38. *Panicum miliaceum* L. Broomcorn Millet,

Hog Millet

Map 330

This is the species usually referred to in Europe as Common Millet, whereas in the United States Common Millet refers usually to *Setaria italica*.

Flowers mid-June–November.

Introduced in waste and cultivated ground and along railroads. Known from central Missouri in St. Louis (*Muehlenbach* 667, 1433, 1479), Morgan (*Versailles*, *Parker Rodgers*), Chariton (Swan Lake Refuge, *Kucera*), and Jackson counties.

Native of the Old World; introduced into the United States where scattered over most of the eastern and central sections.

This hairy-leaved annual, which attains a height

of about 1 meter, but also is often dwarfed to 1 dm. tall, usually does not persist in the wild state. Originally introduced into the northeastern United States for its forage value, the seed was also used for feeding hogs as well as in mixtures of commercial birdseed. In China the straw of this species is used as a pulp in papermaking. In parts of China and in India the seed constitutes an important cereal food, supplementing the widely-used rice.

39. *Panicum virgatum* L. var. *virgatum*

Switch Grass

Map 331

Panicum virgatum L. [G, P & S, BB]

Flowers July–September.

Frequents a wide variety of habitats, usually sunny, including dry or moist prairies, moist seepage of rocky glades and bluff escarpments, rocky banks and gravel bars of streams, wet or dry open woods, and along railroad tracks. Found throughout Missouri, except apparently absent in the extreme southeastern lowland and extreme northwestern sections.

Ranges from Quebec and New Hampshire to Saskatchewan, south to Florida, Texas, Arizona, Mexico, the West Indies, Central and South America.

All the Missouri material appears to fall into the typical var. *virgatum*, in which the rhizomes are elongate and creeping, and the spikelets are 3.5–6 mm. long, with the first glume acuminate and about 2/3 the length of the spikelet, the 2nd glume long-acuminate and definitely longer than the fertile lemma and fruit.

There is considerable variation in the habit of growth of this species in Missouri, ranging from small plants 3 dm. tall with relatively short inflorescences 5 cm. long, to tall plants 2 meters tall with large inflorescences expanding to 50 cm. long. Immature plants, with closely ascending panicle-branches and smaller young spikelets, appear quite in contrast to mature plants with spreading panicle-branches and large well-developed spikelets. Dwarfed or stunted

331 *Panicum virgatum* var. *virgatum* (Switch Grass)

332 *Panicum agrostoides*

333 *Panicum stipitatum*

plants growing on dry limestone glades or bluff escarpments contrast markedly to those well-developed in prairie swales, moist gravel bars, and similar moist sites.

The grass is quite palatable to livestock, and is a constituent of prairie hay.

40. ***Panicum agrostoides* Spreng.** Map 332

Panicum agrostoides Spreng. (typical) [G]

Panicum agrostoides var. *condensum* (Nash) Fern. [G]

Panicum agrostoides var. *ramosius* (Mohr) Fern. [G]

Flowers July–October.

Frequents wet open places in upland prairies, swampy meadows, borders of ponds and sloughs, moist rocky open ground along creeks, occasionally occurring in moist open woods. Found throughout most of southern and central Missouri, including the southeastern lowland, and southwestern unglaciated prairie sections of the state, extending north to Pike, Audrain, Chariton, and Jackson counties.

Ranges from Maine to Indiana, Illinois, Missouri, and Kansas, south to Florida and Texas.

This species was divided by Fernald into the following three varieties:

- a. Nodes of culms straw-color or pale green, not much contrasting in color with the internodes of the culm, only slightly constricted in the dried specimen; leaves firm; larger leaves with conspicuous whitish midrib 0.3–1 mm. wide at base; spikelets 0.8–1 mm. in diam., purplish or bronze (rarely green), short-pointed, ellipsoid to lance-oblong, closely imbricated (overlapping) on the branches of the inflorescence. b
- b. Panicles 0.8–2.5 dm. long, with widely spreading remote lower and middle branch-
es; culms 2–9 dm. tall; spikelets 1.7–2.2 mm. long . P. AGROSTOIDES var. AGROSTOIDES
- b. Panicles 0.6–4 dm. long, with ascending or closely appressed branches; spikelets 2–2.5 mm. long . P. AGROSTOIDES var. CONDENSUM

- a. Nodes of culms darker than and contrasting with the internodes, conspicuously constricted in the dried specimen; leaves submembranaceous; larger leaves with slender midrib rarely 0.5 mm. wide; terminal panicles 1.5–4 dm. long, loosely open, the branchlets and branches spreading and loosely-flowered; spikelets 0.5–0.8 mm. in diam., green or lead-colored (rarely purplish), slenderly lance-elongated to a long tip P. AGROSTOIDES var. RAMOSIUS

An attempt was made to apply the characters used to separate these varieties to the abundant Missouri material collected. However, so much intergradation and lack of correlation was found in numerous instances that it has not been possible to maintain these varieties in Missouri. Plants with purplish long-pointed spikelets and dark nodes were found together with those having short-pointed green or lead-colored spikelets and pale nodes. Such inconsistent combinations and other similar ones have made the retention of definite varietal characters impractical for separation of specimens.

Panicum agrostoides forms usually large clumps with most of the long leaves crowded toward the base.

41. ***Panicum stipitatum* Nash** Map 333

Panicum agrostoides var. *elongatum* Scribn. [BB]

Flowers August–October.

Wet banks of sloughs and streams and swampy ground. Known only from Dunklin, Wayne, and Shannon counties, southeastern Missouri.

Ranges from Georgia to Texas, north to Connecticut, New York, Pennsylvania, Ohio, Indiana, and southeastern Missouri.

No collections of this have been made since the first decade of this century.

42. ***Panicum anceps* Michx. var. *anceps***

Map 334

Panicum anceps Michx. [G, P & S]

334 *Panicum anceps* var. *anceps*335 *Panicum hians*336 *Panicum obtusum*

Flowers June–October.

Frequents wet prairies, swampy meadows, roadside ditches, borders of streams, moist cherty or sandy ground in valleys, and occasionally low open ground in woodland. Rather common in favored wet sites throughout southern Missouri, except absent in most of the southeastern lowland section, extending north to St. Louis, Franklin, Osage, Camden, St. Clair, and Cass counties.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Missouri, and Kansas.

Another variety, var. *rhizomatum* (Hitchc. & Chase) Fern., is found from Virginia to Florida west to Texas.

A well-marked species, with spikelets much larger than *P. agrostoides* and obliquely set above the first glume, the spikelets presenting the appearance of being curved or turned to one side. Often found growing with *P. agrostoides* for which it is sometimes superficially mistaken.

43. *Panicum hians* Ell.

Map 335

Flowers June–October.

Frequents swamps, streams, spring branches, swaley ground, roadside ditches, and low wet woods in the southeastern lowland section of the state.

Ranges from Florida to Texas and New Mexico, north along the Coastal Plain to Virginia, north up the Mississippi Embayment to southeast Missouri, and west to Oklahoma.

This is the only species of *Panicum* in Missouri showing a restricted Atlantic Coastal Plain–Mississippi Gulf Embayment type of geographic distribution. As a characteristic species of the Mississippi Embayment, it grows in bald cypress-swamp tupelo wet woodlands

where it is associated with other species, such as *Diodia virginiana*, of similar distribution.

The very slender wiry culms of *P. hians* are much more slender than those of any other species of *Panicum* in Missouri.

44. *Panicum obtusum* HBK. Vine Mesquite

Map 336

Flowers June–October.

Introduced in Jackson County (Kansas City, July 29, 1905, *Bush 3107*, and August 2, 1903, *Bush 1832*), the only known Missouri station.

Ranges from Kansas to Colorado, south to Texas, Arizona, and northern Mexico.

This species is a wiry-stemmed perennial spreading by long stolons or runners, which may reach a length of nearly 3 meters, rooting at the nodes. The nodes of the culm are conspicuously soft-hairy. The elongated leaf-blades are 2–7 mm. wide and mostly glabrous.

Because of its habit of forming dense mats of runners, this grass has been used to cover banks of streams to prevent erosion.

Excluded Species

5. *Panicum consanguineum* Kunth.

This species was reported by Palmer and Steyermark (Rh. 57: 311. 1955) as occurring in New Madrid County (wooded oak-hickory sandy knoll, on Crowley Ridge, T26N, R14E, sect. 34, 4½ mi. southeast of Sikeston, May 18, 1950, *Steyermark 69667*). This has been found to be a misidentified specimen of *P. malacophyllum* Nash, as determined by Dr. George B. Van Schaack. I have verified Dr. Van Schaack's determination.

Plate no. 61. 1. *Panicum anceps*; a. Spikelet, $\times 7\frac{1}{2}$; b. Floret, $\times 7\frac{1}{2}$. 2. *Panicum virgatum*; a. Plant, $\times \frac{3}{8}$; b. Floret, $\times 7\frac{1}{2}$; c, d. Two views of spikelet, $\times 7\frac{1}{2}$. 3. *Echinochloa colonum*, $\times \frac{3}{4}$. 4. *Panicum hians*; a. Spikelet, $\times 7\frac{1}{2}$; b. Floret, $\times 7\frac{1}{2}$. 5. *Panicum stipitatum*; a, b. Two views of spikelet, $\times 7\frac{1}{2}$; c. Floret, $\times 7\frac{1}{2}$. 6. *Panicum agrostoides*; a. Panicle, $\times \frac{3}{4}$; b. Floret, $\times 7\frac{1}{2}$; c, d. Two views of spikelet, $\times 7\frac{1}{2}$.

2
PLATE NO. 61

12. *Panicum spretum* Schultes

This species was included in the Palmer & Steyermark *Catalogue* from New Madrid and Jasper counties. The Jasper County specimen, upon re-examination, proves to be *P. lanuginosum* var. *Lindheimeri*. The specimen from New Madrid County has not been found.

14. *Panicum meridionale* Ashe

Reported from Missouri by Gleason in the *New Britton & Brown Illustrated Flora*, but no authentic material has been found to substantiate this report. Specimens so labelled, such as *Bush 5741* from McDonald Co. are *P. subvillosum*, and are so treated at the United States National Herbarium. Bush's specimens at the New York Botanical Garden (*Bush 5741*, *5741A*, and *5741B*) have spikelets 1.8–1.9 mm. long with the first glume 0.8–0.9 mm. long and about $\frac{1}{2}$ the length of or slightly less than $\frac{1}{2}$ the length of the spikelet, longer than broad, and acute or acutish at apex; the lower portion of the axis of the panicle varies from hairs appressed-ascending to variously spreading. The hairs on the leaf-sheaths and culms vary from non-papillose to papillose. The ligule is 3–4 mm. long, the hairs on the upper surface of the erect blades are 3–4 mm. long, those on the lower surface dense, appressed, and 0.2–1 mm. long.

The larger spikelets would remove these collections immediately from consideration in *P. meridionale* in the treatments of *Panicum* by Gleason, Fernald, Hitchcock, and Deam, whereas the combination of larger spikelets, acutish longer than broad first glumes nearly $\frac{1}{2}$ the length of the spikelet, and spreading-ascending to appressed hairs of the lower axis of panicle are various characters shared by *P. subvillosum*, although the Bush specimens do not especially show sheaths equaling or longer than the internodes, a character stressed by Fernald.

Although some of the same characters, as above given, are found in *P. praecocius*, the hairs of the leaf-sheaths and culms in that species are mostly 2–6 mm. long and widely spreading. Since the Bush specimens have hairs on the leaf-sheaths and culms mainly less than 2 mm. long and often ascending or even appressed (they are also spreading), this last character of pubescence of leaf-sheath and culm would place the Bush material in *P. subvillosum* rather than *P. praecocius*.

One other specimen, *Bush 15595* (woods, Baxter, Stone Co., May 27, 1936) in the Missouri Botanical Garden Herbarium, labelled by Bush as *P. meridionale*, should be referred to *P. lanuginosum* var. *fasciculatum*.

19. *Panicum columbianum* Scribn.

A specimen in the herbarium of the University of Missouri labeled 'Columbia, Mo., coll. B. T. Galloway, Aug. 1, 1884 legit Vasey.' was determined as *P. tsugetorum* Nash by either Hitchcock or Chase in Mrs. Chase's inked handwriting. Underneath this inked determination is a note by Hitchcock, 'I am uncertain about this.' The specimen is cited in Daniel's *Flora of Columbia, Missouri*, identified by Bush as '? *P. subvillosum* Ashe.'

The specimen has appressed-pubescent leaf-sheaths and lower leaf surfaces, the hairs on the lower leaf surface being short and fine, while the upper leaf surfaces are glabrous. The ligules vary from 2–4 mm. long. The spikelets are about 2 mm. long, pubescent, and with the 1st glume triangular-ovate and $\frac{1}{3}$ – $\frac{3}{8}$ the length of the spikelet. The axis of the inflorescence is glabrous or nearly so. The specimen is not typical *P. columbianum*, as the ligules attain a length of 4 mm.

Since the locality as well as the collector (both Galloway and Vasey are cited on the label) is doubtful, it seems better to exclude the species.

70. *Echinochloa* Beauv. Barnyard Grass

Annual grasses with long leaf-blades, compressed (flattened or folded) leaf-sheaths, and green or purple inflorescences composed of 1-flowered spikelets densely crowded along one side of thick racemes pinnately spreading or ascending from the main axis. The 1st glume is the shortest of the parts present on the spikelet. The 2nd glume and sterile lemma have a rather thin membranous texture similar to that of the 1st glume, but are much longer and about equal the length of the spikelet. The fertile lemma and palea are much thicker, coriaceous (leathery), smooth, and shining.

- a. Racemes (main side branches of inflorescence) mostly 1–3 cm. long; leaf-blades mostly 2–6 (rarely to 10) mm. wide; spikelets (excluding awns) mainly 2–2.5 mm. (rarely to 2.9) long; few or no long hairs or bristles present on rachis and at nodes of inflorescence. I. E. COLONUM
- a. Racemes mainly 3–12 cm. long (rarely shorter); leaf-blades mainly 5–30 mm. wide; spikelets (excluding awns) 2.5–4.5 mm. long; long hairs and bristles often present and common on rachis and at nodes of inflorescence. b

- b. Some part of the spikelet with a conspicuous or long awn c
- c. Swollen- or blister-based stiff hairs present on all or most nerves in addition to those on marginal nerves of 2nd glume and sterile lemma; use a magnification of 15 × or more to observe that the summit of the smooth shining fertile lemma tapers into a *long* rather firm acuminate (well-pointed) or nearly acuminate tip lacking a ring of microscopic hairs; conspicuous long and bristle-like hairs few or sometimes absent at the nodes (joints) and along the rachis of the branches of the inflorescence 3a. *E. MURICATA* var. *MURICATA*
- c. Hairs, when present on 2nd glume and sterile lemma, fine and slender from base to tip, the swollen- or blister-based hairs, if present at all, occurring only on marginal nerves; use a magnification of 15 × or more to observe that the summit of the smooth shining fertile lemma tapers into a *short* soft, easily bent, or wrinkled obtuse (blunt) tip with a ring of microscopic hairs present where the shining summit grades into the softer dull tip; conspicuous long and bristle-like hairs frequent at the nodes and sometimes along the rachis of the inflorescence 2b. *E. CRUSGALLI* var. *CRUSGALLI* f. *LONGISETA*
- b. Spikelets either completely without awns, or at most with a short awn, never with a long or conspicuous awn d
- d. Swollen- or blister-based hairs present on all or most nerves as well as the margins of 2nd glume and sterile lemma 3d. *E. MURICATA* var. *MICROSTACHYA*
- d. Swollen- or blister-based hairs either absent or present only on the marginal nerves of 2nd glume and sterile lemma e
- e. Use a magnification of 15 × or more to observe that the summit of the smooth shining fertile lemma tapers into a *long* firm acuminate (well-pointed) or nearly acuminate tip lacking a ring of microscopic hairs; conspicuous long and bristle-like hairs few or absent at the nodes (joints) and along rachis of the inflorescence f
- f. Spikelets mainly 3.3–4.5 mm. long, 1.8–2.2 mm. wide 3b. *E. MURICATA* var. *LUDOVICIANA*
- f. Spikelets mainly 2.5–3.4 mm. long, 1.4–1.8 mm. wide 3c. *E. MURICATA* var. *OCCIDENTALIS*
- e. Use a magnification of 15 × or more to observe that the summit of the smooth shining fertile lemma tapers into a *short* soft, easily bent, or wrinkled obtuse (blunt) tip with a ring of microscopic hairs present where the shining summit grades into the softer dull tip; conspicuous long and bristle-like hairs frequent at the nodes and sometimes along the rachis of the inflorescence g
- g. Spikelets glabrous or sterile lemma with minute sparse appressed hairs; sterile lemma soft-tipped, obtuse (blunt); inflorescence rather narrowly oblong and dense, dark brown-purple, the tips of branches turning inward; branches of inflorescence overlapping 2c. *E. CRUSGALLI* var. *FRUMENTACEA*
- g. Spikelets mostly fine and slender, setiform (of a bristly type), the swollen- or blister-based hairs, if present, occurring only on margins of 2nd glume and sterile lemma; sterile lemma firm-tipped, abruptly short-pointed (apiculate); inflorescence with a pyramidal or Christmas-tree shape (broadly ovoid, rhomboid, or lanceolate), green or purple, the branches straight; branches of inflorescence not overlapping 2a. *E. CRUSGALLI* var. *CRUSGALLI*

1. ***Echinochloa colonum* (L.) Link f. *colonom***
 Jungle Rice Map 337
Echinochloa colonum (L.) Link [G, P & S]
 Flowers July–October.

Moist ground along fields, roadside ditches, and along railroads. Introduced in southeastern, east-central and west-central Missouri, in Jackson (Sheffield, September 16, 1920, *Bush 9228*), St. Louis (Burlington R. R. right-of-way beneath Merchants Bridge, St. Louis, July 5, 1954, *Muehlenbach 224*), Mississippi, and Pemiscot counties.

Native of the Old World; introduced into the United States, ranging from Florida and Texas to California, north to New England, Pennsylvania, Ohio, Illinois, and Missouri; also in Mexico, Central

America, and in most tropical regions of the Old and New World.

Of all the species of *Echinochloa* in Missouri, this one is the smallest in all parts: in stature, length of leaf-blades (mainly 5–10 cm. long). Plants are cultivated in tropical Asia and Africa for their seeds, which are made into a flour for food.

2a. ***Echinochloa crusgalli* (L.) Beauv. var. *crusgalli* f. *crusgalli*** Barnyard Grass
 Map 338

Echinochloa crusgalli (L.) Beauv. [G, BB, P & S]
 Flowers June–November.

Scattered throughout the state, where, it occurs along roadsides, moist ditches, moist ground along

authorship, acc. to Fairbrothers, Rh. 58: 48. 1956

Echinochloa pungens (Poir.) Rydb. [G, BB, Fassett]

Echinochloa crusgalli (L.) Beauv. subsp. *muricata*

(Michx.) Shinnars, Rh. 56: 33. 1954.

Flowers July–October.

Frequents usually low or moist ground in the open or shade by borders of ponds, oxbow lakes in alluvial flood plains of wooded or open river bottoms, muddy banks and gravel bars of streams, dried up mud flats, waste, and cultivated ground; often a weed in gardens. Throughout the state, and apparently the commonest of the variations found.

Ranges from Maine to Minnesota, south to North Carolina, Tennessee, Arkansas, and Oklahoma.

3b. *Echinochloa muricata* var. *ludoviciana*

Wieg.

Map 339

Echinochloa pungens var. *ludoviciana* (Wieg.) Fern. & Grisc. [G, P & S]

Echinochloa crusgalli ssp. *muricata* var. *muricata*

(Michx.) Farwell [of Shinnars, in part Rh. 56: 34. 1954]

Ranges from Mississippi to New Mexico, north to Virginia, Pennsylvania, Tennessee, and Missouri.

Grisc. [G. Fassett]

Echinochloa crusgalli var. *microstachya* (Wieg.) Shinners, Rh. 56: 34. 1954.

Similar situations as var. *muricata*. Scattered over the state, but apparently the rarest of the varieties in the state.

Ranges from Quebec and Ontario to Wyoming, south to New England, Pennsylvania, Michigan, Illinois, Missouri, Texas, and Mexico.

In view of recent changes in rules of nomenclature, the name *Echinochloa muricata* (Beauv.) Fern., as interpreted by Fairbrothers (Rh. 58: 48. 1956) is followed in the present treatment, and supplants the previously used *E. pungens* (Poir.) Rydb.

This species and others of the genus have been reported to be involved as possible causes of hay fever.

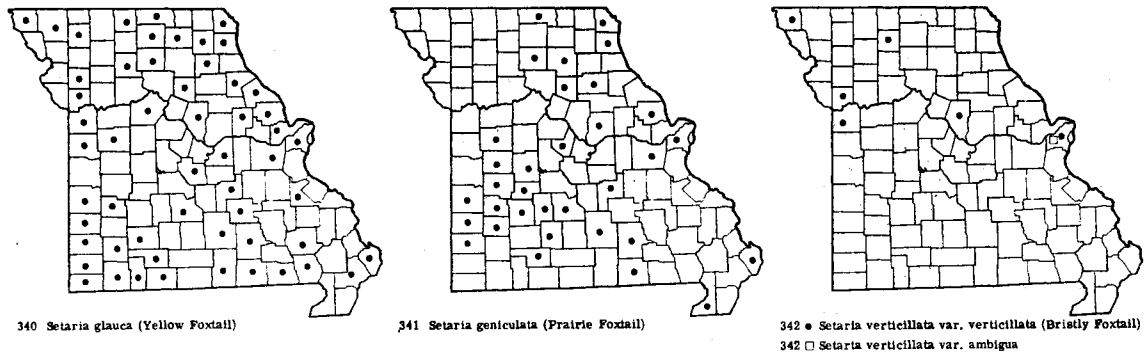

The seeds principally of *E. muricata* var. *occidentalis*, var. *microstachya*, other western varieties of *E. muricata* and of *E. crusgalli* var. *zelayensis* and other varieties, serve the Indians of the western United States as food in the form of a starchy flour.

The several varieties, although palatable, and occasionally cut for hay or used for forage, have never become economically important for grazing animals.

71. *Setaria* Beauv. Foxtail Grass

Annual or perennial grasses with dense cylindrical, spike-like inflorescences. Spikelets similar to *Panicum*, except that they are surrounded by an involucre of 1-many bristles, which persist after the spikelets fall. The ligule consists of a stiff band of white hairs of varying length. Spikelets may be articulated above, but usually below the glumes.

- a. Leaf-sheaths with an edge of fine hairs on some part of the margins; each spikelet with 1-3 bristles attached below its base (caution must be used here not to include bristles from adjacent spikelets) . . . b
- b. Bristles of the inflorescence barbed downwardly (catching on to clothes or rough objects easily); lower length (internode) of inflorescence usually showing between the clusters of spikelets . . . 3a. *S. VERTICILLATA* var. *VERTICILLATA*
- b. Bristles of the inflorescence barbed upwardly (not catching on clothing or to rough objects) . . . c
- c. Upper surface of leaf-blades with usually many hairs, less frequently with few or no hairs . . . 5. *S. FABERII*
- c. Upper surface of leaf-blades completely glabrous (rarely with a few hairs) . . . d
- d. Top of peduncle (main stalk supporting inflorescence) with backward- or downward-pointing rough hairs (retrorse-scabrous); leaf-blades loosely spreading. . . 3b. *S. VERTICILLATA* var. *AMBIGUA*
- d. Top of peduncle with upward-pointing fine appressed hairs (lying close to and parallel with axis); leaf-blades usually erect or ascending . . . e
- e. Inflorescence narrowly cylindrical, dense, not interrupted, and of nearly same diameter from base to tip, 0.5-2.3 cm. thick, including the bristles; when seeds are mature, the whole spikelet falls together, the seed remaining covered by glumes and lemma; leaves 5-15 mm. wide . . . 4. *S. VIRIDIS* var. *VIRIDIS*
- e. Inflorescence ovoid or broadest in lower half, lobed, or with numerous, short branches, interrupted, or in dwarfed specimens often dense and not interrupted, 1.5-4 cm. thick (sometimes in dwarfed specimens only 1 cm. thick), including the bristles; when seeds are mature, they fall from rest of spikelet, leaving the glumes and lemma to remain on the inflorescence; leaves often 15-30 mm. wide (sometimes narrower and only 6-7 mm. wide in dwarfed specimens) . . . 6. *S. ITALICA*
- a. Leaf-sheaths with glabrous margins; each spikelet with a cluster of 5-20 bristles attached below its base . . . f
- f. Spikelets mainly 1.9-2.9 mm. (rarely 3) long; perennial plant; culms arising singly or in small tufts from branched underground rhizomes (culm breaks away easily above ground when not carefully collected with rhizome); each spikelet with a cluster of 8-12 bristles attached below its base; leaf-blade (upon drying) with a half twist or loose spiral . . . 2. *S. GENICULATA*
- f. Spikelets 3-3.5 mm. long; annual plants; culms arising in large tufts from fibrous roots; each spikelet with a cluster of 5-20 bristles attached below its base; leaf-blades straight, without a twist . . . 1. *S. GLAUCA*

1. ***Setaria glauca* (L.) Beauv.** Yellow Foxtail

Map 340

Setaria lutescens (Weigel) Hubbard [P & S, Fassett]
Flowers early June–October.

Occurs as a weed in waste and cultivated ground, gravel bars along streams, along roadsides, railroad tracks, in fields, pastures, gardens, and open places. Throughout Missouri.

Native of Europe and Asia; introduced into North America, ranging from Nova Scotia and Quebec to South Dakota, south to Florida, Texas, and westward to a lesser extent.

For a discussion of the proper Latin name of this plant, see John R. Reeder (Rh. 53: 27–30. 1951).

The bristles are at first green, but eventually turn a tawny, yellow-brown, or golden-brown color, and are 2–2½ times the length of the spikelet. They are similar in color to those of the perennial species, *S. geniculata*. The culms and leaf-sheaths are flattened or compressed and keeled, giving the culms a broad, flat appearance, especially near the base where they are 5 mm. or more wide. The leaf-blades have a glaucous- or pale blue-green color on the upper surface. The upper surface of the blades is usually glabrous but occasionally may have a few long, slender hairs. As they dry, they present a half twist or loose spiral.

The seeds of this and the other species of *Setaria* are sometimes prepared into a flour or mealy substance.

2. ***Setaria geniculata* (Lam.) Beauv.**

Prairie Foxtail

Map 341

Flowers July–October.

Occurs in prairies or prairie remnants along railroads, often in sandstone or cherty soil, and occasionally on limestone glades. Most common on prairies in the unglaciated prairie region of southwestern Missouri, scattered elsewhere in prairie openings in the

northeastern half of the state and in parts of the Ozark section. Absent from northwestern Missouri, and most of the eastern Ozark section.

Ranges from Argentina north into Central America, Mexico, and the West Indies, and from Florida to Texas, north along the coast to Massachusetts, in the interior north to Pennsylvania, Illinois, Missouri, Kansas, New Mexico, and California.

This is the only perennial and native species of *Setaria* in Missouri. It is easily identified by the short underground branched rhizomes.

3a. ***Setaria verticillata* (L.) Beauv. var. *verticillata*** Bristly Foxtail, Bur Bristlegrass Map 342
Flowers early June–October.

Occurs along railroad tracks, waste places, gardens, and along streets in some of the larger cities. Rare, known from several counties in the northern half of the state.

Native of the Old World; introduced into the United States, ranging from New Hampshire to North Dakota, south to Virginia, Alabama, Louisiana, and Texas. Also introduced as a weed in gardens and coffee plantations in Guatemala, and in temperate and warm regions of the New and Old World.

In certain parts of Africa the mature inflorescences of this species serve the native inhabitants to keep rats away from stored grain; the adherence of the reversed barbed bristles of mature inflorescences to the fur of these animals acts as a nuisance value preventative.

3b. ***Setaria verticillata* var. *ambigua* (Guss.)**

Parl.

Map 342

Setaria viridis var. *ambigua* (Guss.) Cosson & Durand [BB]

Introduced along railroads, where known from one recent collection in St. Louis County (Terperance St. freight yard of Mo.-Pac. R. R. [refrigerator car division] along the wooden ramp, south of Rutger

343 *Setaria viridis* var. *viridis* (Green Foxtail)344 • *Setaria Faberii* (Nodding Foxtail)
344 □ *Setaria Faberii* X *Setaria viridis*345 *Setaria italica* (Common Millet)

Street, St. Louis, August 4, 1957, *Muehlenbach* 1295).

The var. *ambigua*, in addition to the upwardly barbed bristles of the inflorescence, differs from var. *verticillata* in having the axis of the inflorescence scabrous (rough to the touch with short stiff projections) instead of hairy as in var. *verticillata*.

The inflorescences of both varieties are of a deep green color and mostly erect and tapering at the tip, and more or less lobed or divided into short rounded dense clusters. The small spikelets (averaging 2 mm. long) are subtended by usually one but rarely 2, bristles.

4. *Setaria viridis* (L.) Beauv. var. *viridis*

Green Foxtail

Map 343

Flowers June–October.

Similar to the habitat of the Yellow Foxtail (*S. glauca*) and frequently associated with it. Occurs throughout Missouri.

Native of Europe; introduced into North America, where naturalized from Newfoundland to British Columbia, south to Florida, California, and Mexico.

Aside from the difference in leaf-sheaths, this species is easily distinguished from *S. glauca*, which it resembles, by the much smaller spikelets 1.9–2.5 mm. long, with the bristles 3–4 instead of 2–2½ times the length of the spikelets, the much more slender terete or subterete culms, and rather rounded, not compressed, leaf-sheaths, the culms mainly 1–2 mm. wide near the base, and by the deeper green leaf-blades, which are straight, not half-twisted. The spike-like inflorescence may be erect, but tends to nod slightly at the tip, whereas it remains stiffly erect in *S. lutescens*. The color of the bristles in *S. viridis* may be either green or purple, the younger inflorescences frequently being greener.

Although no Missouri specimens have been seen of *S. viridis* var. *Weinmanni* (R & S) Brand, its eventual occurrence in the state is very probable. It differs from *S. viridis* var. *viridis* in the more slender and shorter inflorescences (1–4 cm. long and 5–10 mm. thick), shorter bristles, shorter culms, and generally narrower leaves (to as narrow as 2 mm.). Its known range in North America is from Newfoundland to Ontario, Wisconsin, and Iowa, south to New England, Virginia, and elsewhere.

5. *Setaria Faberii* Herrm.

Nodding Foxtail

Map 344

Flowers July–October.

Introduced in cultivated fields, waste ground along roadsides, railroad tracks, gravel bars along streams, and open places. Rapidly spreading throughout the state.

Native of China; recently introduced into the United States, and known in this country since 1931; now recorded from Massachusetts and Pennsylvania to Illinois and Nebraska, south to North Carolina, Tennessee, and Missouri.

This grass is becoming more common each year, and it is known from all sections of the state except the southeastern quarter, where it has not yet been recorded, except from Mississippi County. It is now spreading along all the highways.

It is much taller and usually more robust in length and width of inflorescence and leaves than *S. viridis* var. *viridis*, which it resembles. The usually curved or nodding spikelike inflorescences, which droop from a point near their bases, and the usually more or less hairy upper surface of the leaf-blades are other characters used to distinguish this species. The spike-

Plate no. 63. 1. *Setaria Faberii*, × ¾. 2. *Setaria italica*; a. Panicle and leaf, × ¾; b. Floret, × 3¾. 3. *Setaria geniculata*, × ¾. 4. *Cenchrus longispinus*; a. Bur, × 3¾; b, c. PLATE NO. 63

lets, moreover, are larger (2.6–3 mm. long) than those of *S. viridis* var. *viridis*. The lower surface of the leaves in *S. Faberii*, while often minutely pubescent, may also be glabrous, while *S. viridis* var. *viridis* has the leaves completely glabrous on both sides. Occasional plants of *S. Faberii* are found which are completely glabrous, as in *S. viridis* (Rh. 61: 220–23. 1959). The leaf-blades of *S. Faberii* are usually of a paler yellow-green as contrasted to a darker green of *S. viridis* var. *viridis*.

Sometimes plants are found which appear to be natural hybrids between *Setaria viridis* and *S. Faberii*. One such collection has been found in Lewis County. More, undoubtedly, will be collected.

6. *Setaria italica* (L.) Beauv.

Common Millet

Map 345

This is also known under other common names, such as German, Italian, Hungarian, and Japanese Millet, and Hungarian Grass. *Echinochloa crusgalli* var. *frumentacea*, sometimes called Japanese Barnyard Millet, is more properly designated Japanese Barnyard Millet. The Common Millet of Europe refers usually to *Panicum miliaceum*, not to *Setaria italica*.

Flowers July–October.

Escaped from cultivation to waste ground, roadsides, and along railroads. Scattered throughout the state.

Native of Europe and Asia; cultivated in the warm-

er parts of the United States, but escaped throughout the country.

This ranges through a number of variations, differing principally in the color of fruits and bristles and in the degree of lobing of the inflorescence.

Forms with fruit blackish, brownish black, or purplish black are usually called Hungarian Grass (*S. italica* subsp. *nigrofructa* Hubb.). Those with the fruit orange, yellowish to straw-colored or light brown are divided into forms with green bristles, purple bristles, and brown bristles. Further subdivision is carried out on the basis of the degree of lobing of the panicle. Forms of the so-called German Millet occur under the types having orange or yellowish to straw-colored or light brown fruits; in some forms of German Millet, the bristles may be green (*S. italica* subsp. *stramineofructa* Hubb.), in other forms of German Millet the bristles are purple (*S. italica* var. *Hostii* Hubb.).

For a detailed classification of these various subdivisions of the species, the work of F. T. Hubbard (Am. Jour. Bot. 2: 187–88. 1920) should be consulted.

In the United States *S. italica* is usually cultivated as a fodder plant. In parts of Asia the seeds are used as a food plant. At various times in Europe the seeds have been used in puddings and boiled in soups and sauces.

72. *Cenchrus* L. Sandbur

Cenchrus longispinus (Hack.) Fern.

Sandbur

Map 346

Cenchrus pauciflorus of many recent authors, not Benth. [BB, Hitchcock, P & S]

Flowers late May–October.

Frequents waste ground, roadsides, railroads, and fields; especially common on sand or in sandy light soils of any kind.

Now widespread over the entire state.

Ranges from New Hampshire to Oregon, south to North Carolina, Kentucky, Missouri, Kansas, and New Mexico.

The spiny globelike burs of this grass easily become detached when mature and lie on the ground where they can cause sudden pain to barefoot children or unsuspecting fingers. These burs attach themselves easily to clothes or other objects with the slightest contact. The spines easily puncture the flesh of grazing animals, causing dangerous wounds. By lodging in the wool of sheep, the burs cause damage to the fleece. In some parts of Africa another species of *Cenchrus* is used by one of the tribes for its edible seeds, from which a cooling drink is made, or as an ingredient or constituent of porridge and other foods.

Tribe XI. ANDROPOGONEAE

Grasses of this tribe have the spikelets occurring in usually 2's, sometimes 3's at each joint of the rachis, one of the spikelets usually stalkless (sessile), perfect and fertile, the other one or two stalked (pedicelled) and either staminate, sterile, or rarely perfect, or lacking, with only the stalk present. The perfect fertile spikelet consists of 1 terminal floret, the fertile lemma of which is often awned, and below this, a staminate or sterile floret represented by 2 or 1 empty awnless glumes. The spikelets are articulated below the glumes. The glumes are firm or hardened, while the sterile and fertile lemmas are thin and transparent.

346 *Cenchrus longispinus* (Sandbur)

347 *Miscanthus floridulus* (Eulalia)

348 *Erianthus strictus* (Narrow Plume Grass)

73. *Miscanthus* Anderss.

Tall perennial grasses with long leaves and large inflorescences of numerous fan-shaped, plume-like showy, silky hairy racemes. The spikelets are all uniform, perfect, and occur in pairs along the rachis, the latter being continuous and not breaking up into segments.

Miscanthus floridulus (Lab.) Warb. Eulalia
Map 347

Flowers September–November.
Escaped from cultivation along railroads, where known only from St. Louis County (along right-of-way of Terminal Railroad, between West Florissant Ave. and Broadway, opposite Hussmann Refrigerator Company plant, St. Louis, October 1, 1955, *Muehlenbach* 822A; and Carrie Avenue freight yard of Rock Island Railroad, in the northeastern corner, about 100 m. southeast of the station, St. Louis, November 27, 1955, *Muehlenbach* 860).
Native of eastern Asia; escaped from cultivation as an ornamental grass in the United States, where

naturalized from Florida to Mississippi and Texas, north to Massachusetts, New York, Ohio, and Missouri.

Although frequently cultivated in Missouri, this species is known to have become naturalized in the state only from the above stations.

The Missouri material was originally identified and published under the name of *M. sinensis* Anderss. However, as pointed out to the present author by Drs. Fosberg and Van Schaack, that species has narrower leaves 3–5 mm. wide and barely exserted panicles, whereas the more commonly cultivated species with broader leaves and truly exserted panicles is *M. floridulus*.

74. *Erianthus* Michx. Plume Grass, Beard Grass

Tall perennial grasses with long leaves and long inflorescences of numerous crowded racemes often covered with silky hairs. One spikelet of each pair is sessile, the other stalked, and the spikelets occur along a jointed rachis which eventually breaks up into distinct segments.

- a. Spikelets awnless, or the awn only 3–6 mm. long; cultivated species escaped along railroads or disturbed areas 3. *E. RAVENNAE*
- a. Spikelets conspicuously awned, the awn 10–20 mm. long; native species of wild natural areas b
- b. Hairs at base of spikelet much longer than the spikelet it surrounds; awn spiral or twisted at or near the base; plants of dry sandy or rocky open woods or open sandy slopes 2. *E. ALOPECUROIDES*
- b. Hairs at base of spikelet either none or of few hairs many times shorter than the spikelet; awn straight, not twisted; plants of moist or wet soil 1. *E. STRICTUS*

1. ***Erianthus strictus*** Baldw.
Narrow Plume Grass
Map 348
Flowers July–October.

Known only from swamps in Dunklin County, southeastern Missouri lowlands (Campbell, October 7, 1910, *Bush* 6384).

Ranges from Florida to Texas, north to Virginia, Tennessee, and southeastern Missouri.

A species of the Atlantic-Gulf Coastal Plain-Mississippi Embayment area found only once in the state. There is reason to believe that it will eventually be found in other sectors of the lowland area of south-

349 *Erianthus alopecuroides* (Silver Plume Grass)350 *Erianthus Ravennae* (Plume Grass)351 *Arthraxon hispidus* var. *hispidus*

eastern Missouri if such places can be located before the present march of industrialization and development has obliterated them.

2. *Erianthus alopecuroides* (L.) Ell.

Silver Plume Grass

Map 349

Flowers September–October.

Frequents sandy or cherty, usually dry open woods or open sandy slopes and thickets in acid soils in southern Missouri, east to Stoddard and Pemiscot counties, north to Iron and Reynolds counties, and west to Barry County.

Ranges from Florida to Texas, north to Virginia, New Jersey, Ohio, Indiana, Illinois, Missouri, and Oklahoma.

This is a very showy species, attaining a height of 3 meters. The beautiful large silvery-white to cream-colored beard of the inflorescence is a most striking feature of the plant. It certainly ranks among the showiest and most spectacular of the native Missouri grasses and merits horticultural recognition for its great ornamental value. It may not respond easily to cultivation or transplanting, however, as it seems

to require an acid soil. Initial experiments which I carried on to raise the species from seeds have failed.

3. *Erianthus Ravennae* (L.) Beauv.

Plume Grass, Ravenna Grass

Map 350

Flowers September–November.

Escaped from cultivation and rarely established.

Known only from railroad tracks in St. Louis County (along ditch west of the right-of-way of Burlington Railroad, north of East Grand Avenue, just opposite Cemco Manufacturing & Supply Company's building, October 17, 1954, *Muehlenbach* 500).

Native of southern Europe; cultivated as an ornamental grass in the United States, and escaped and naturalized from Maryland southward and west to Arizona.

This ornamental grass is often cultivated, but rarely escapes and becomes naturalized, the above station being the only one thus far known in the state. The grass attains 3 meters in height. The spikelets are surrounded by a dense silvery beard which lends beauty to this showy species.

75. *Arthraxon* Beauv.

Grasses with broad deeply heart-shaped leaf-blades and digitate spikes of 1-flowered, sessile spikelets. An awn arises from the back of the 2-toothed fertile lemma, and the seed is very narrowly linear.

Arthraxon hispidus (Thunb.) Makino var.

hispidus

Map 351

Arthraxon hispidus (Thunb.) Makino [G]

Flowers September–October.

Known only from St. Louis County (growing about the margins of the northeast portion of the lagoon at the base of 'Art Hill,' Forest Park, St. Louis, September, 1933, *Steyermark*).

Native to eastern Asia; the Missouri station is the only one known in the United States.

From Florida to Arkansas, north to New York is found *Arthraxon hispidus* var. *cryptatherus* (Hack.) Honda, the more commonly collected, although rare variety in the United States. Like *A. hispidus* var. *hispidus*, it is a native of eastern Asia, but differs from *A. hispidus* var. *hispidus* in the minute or only slightly exerted awn, whereas in *A. hispidus* var. *hispidus* the awn is 5–9 mm. long and conspicuously exerted.

With its papillose-hispid leaf-sheaths and broad ovate-lanceolate, heart-shaped leaf-blades ciliate-

margined at the base, this grass might superficially be mistaken for *Panicum clandestinum*. However, the creeping culms rooting at their nodes, together with the awned spikelets arranged in digitate spikes, quickly dispel any further resemblance to *Panicum clandestinum*.

This grass was reported originally by the author in *Rhodora* 36: 313, 1934, and subsequently in Palmer

& Steyermark, *Annotated Catalogue of Flowering Plants*, as *Arthraxon hispidus* var. *cryptatherus*, the name by which it was determined at the United States National Herbarium. However, as correctly shown by Dr. Fernald, in the eighth edition of *Gray's Manual*, the long awn would place the Missouri collection with typical *A. hispidus* var. *hispidus* rather than with the minute or short-awned var. *cryptatherus*.

76. **Andropogon** L. Beard Grass

Perennial grasses in large clumps with solid stems and long narrow leaf-blades. Inflorescences of solitary, paired, digitate, or panicked racemes. At each joint of the rachis occur spikelets in pairs (of two kinds), one sessile and perfect, the other stalked and staminate, sterile, or not developed. The fertile lemma, which is shorter than the glumes, usually ends in a long awn. The rachis and usually the pedicels (stalks of spikelet) are covered with long silky hairs.

- a. Only 1 raceme (unbranched or separated part) attached to the tip of each peduncle (main support of inflorescence) and, even when crowded, appearing at different levels or heights, or arising from different axes 1. *A. SCOPARIUS*
- a. Two or more racemes attached to the tip of each peduncle (main support of inflorescence) and crowded together to appear as a unit arising from the same axis b
- b. Inflorescence of a lavender, brown-purple, bronze, yellow-brown, green and purple color, or at least not producing long white, gray-white, or silvery-white silky hairs 5-10 mm. long which equal or are longer than sessile spikelets 2. *A. GERARDI*
- b. Inflorescence with conspicuous long white, gray-white, or silvery-white silky hairs 5-10 mm. long, which equal or are usually longer than the sessile spikelets c
- c. Inflorescence a dense narrow panicle of usually 10 or more short racemes (unbranched lateral units) on an elongated axis 6. *A. SACCHAROIDES*
- c. Inflorescence of 2-3 racemes arranged digitately (like fingers on a hand or resembling a V-shape) d
- d. Mature racemes (unbranched units of inflorescence) mostly straight or closely flowered, rather stiff; sessile spikelet 5-6 mm. long, equaling or longer than the sterile pedicel (stalk) alongside it, broadly lanceolate; leaf-sheaths of lower part of plant not strongly keeled nor alternately overlapping the base of each other in 2 ranks (not equitant) 3. *A. TERNARIUS*
- d. Mature racemes rather loosely curving or gracefully flexuous (alternately curving in opposite directions); sessile spikelet 3-5 mm. long, narrowly or linear-lanceolate, shorter than the sterile pedicel (stalk) alongside it; leaf-sheaths of lower part of plant compressed, keeled at the back, and alternately overlapping the base of each other in 2 ranks (equitant) . . . e
- e. No tufts of hair occurring on the culms just below the nodes; awn of fertile sessile spikelet not spiraling or twisted at the base; the shortened leaf-like parts (spathe) at the side or base of each inflorescence not inflated nor strongly overlapping at maturity. 4. *A. VIRGINICUS*
- e. Conspicuous tufts of white hairs occurring on the culms just below the upper nodes at least (best observed at the base of the leaf-like spathes); awn of fertile sessile spikelet spiraling or twisted at the base; the shortened leaf-like parts (spathe) at the side or base of each inflorescence inflated at maturity or strongly overlapping 5. *A. ELLIOTTII*

Flowers September-October.

352 *Andropogon scoparius* (Little Bluestem)353 • *Andropogon Gerardii* var. *Gerardii* (Big Bluestem)353 □ *Andropogon Gerardii* var. *chrysocomus*354 *Andropogon ternarius*

Occurs in prairies, glades, rocky open woods, abandoned fields, sandy open ground, waste places, and along railroads.

Throughout Missouri, except absent in the southeastern lowlands.

Ranges from New Brunswick and Quebec to Alberta, south to Florida, Texas, and Arizona.

In the beginning at flowering time, in a young stage of development, or when moist, the racemes are more or less straight and slender, but at maturity or upon drying, the racemes become curved or arched and expose the grayish-white hairs which stand out on the rachis-joints and sterile pedicels. The ligule is a brownish membrane about 1.5 mm. high with a subtruncate, irregularly broken border often fringed with tiny white hairs.

Several varieties of *Andropogon scoparius* have been described by Hubbard (Rh. 19: 100-105. 1917) and by Fernald & Griscom (Rh. 37: 143-46. 1935). An attempt has been made to fit the abundant Missouri material on hand for study into some of these varieties, but, as will be judged from the above synonymy, the treatment by Fernald and Griscom has not been found to be applicable nor adequate. So little correlation can be found between the bearding on the joints of the rachis and the length of the glumes of the fertile spikelets, or between the number of spikelets in a raceme and the length of the sterile rudiment, that there appear to be no well-defined constant correlations in these characters with the Missouri material. In this respect, the writer is in agreement with Fassett (*Grasses of Wisconsin*, p. 92. 1951) who found Fernald & Griscom's treatment unworkable for Wisconsin. Deam (*Flora of Indiana*, pp. 178-79. 1940, *Grasses of Indiana*, p. 318. 1929) likewise was unable to find

adequate criteria for a satisfactory separation of the Indiana material.

Practically all the Missouri material examined has the basal third of the joints of the rachis without any beard and would be interpreted, following Fernald's treatment, as *A. scoparius* var. *scoparius* f. *calvescens*, f. *scoparius*, or var. *polycladus*, but a few might be placed in var. *frequens* or var. *neomexicanus* where bearding is denser. The most obvious variations in the Missouri plants are in glabrous versus pubescent culms and leaves, and in their green versus their silvery-blue or silvery-glaucous appearance. Particularly striking are plants on the 'bald knobs' and limestone glades in southwestern Missouri, whole colonies of which for acres in extent possess silvery-glaucous or blue-glaucous culms and leaves, the latter varying from glabrous to strongly villous. Such plants could be referred to *A. scoparius* var. *scoparius* f. *scoparius*, f. *calvescens*, or var. *polycladus*, with some showing more bearding near the basal third and transitional toward var. *neomexicanus*. One such collection (bald knob, Malva, Taney County, September 17, 1924, *Palmer 26170*) has been identified by Fernald as var. *neomexicanus* in the Gray Herbarium. Shinnars (Rh. 56: 37. 1954) notes that this variety in Texas has 'the whole plant . . . pale or glaucous.' A collection from Taney County (*Steyermark 66368*) representing this glaucous phase shows sparse bearding on the lower third of some rachis joints as in var. *neomexicanus*, but most of the joints are free of bearding in the lower third and are thus characteristic of *A. scoparius* f. *calvescens*. The glaucous and green phases in other parts of Missouri often occur together, such as *Steyermark 25957* and *25958* from Lincoln County, *Steyermark 23839* and *23840* from Webster County, *Steyermark 24040* and *24041* from

PLATE NO. 64

Polk County, and *Steiermark* 25341 and 25342 from Phelps County, with sometimes the green phase and other times the glaucous phase predominating. Since both glabrous or pubescent glaucous plants may be found along with glabrous or pubescent green plants among the populations on the glades and elsewhere, and variations may be found in the amount of bearding on the rachis joints, the applicability of the names var. *scoparius* f. *scoparius* and f. *calvescens*, and var. *neomexicanus*, to fit given plants is uncertain.

Andropogon scoparius is a valuable forage grass and provides good grazing when young. It is considered to be of some significance in causing hay fever. In late autumn and through the winter, Little Bluestem is conspicuous over large sections of open landscape, covering bare fields, prairies, and railroad sidings with ornamental clumps of russet-brown or tan dried leaves and stems.

2. **Andropogon Gerardi** Vitman Big Bluestem,
Bluejoint Turkeyfoot Map 353
Flowers June–September.

Occurs in prairies, glades, open rocky woods, and along railroads.

Missouri material may be classified into two varieties:

Hairs of rachis and pedicels white, 1–2 mm. long; glumes of sessile spikelet usually scabrous with short rough projections; common type throughout Missouri . . . 2a. *A. GERARDI* var. *GERARDI*

Hairs of rachis and pedicels creamy to yellowish-white, 2–4 mm. long; glumes of sessile spikelet smoother; southwestern Missouri . . . 2b. *A. GERARDI* var. *CHRYSOCOMUS*

2a. **Andropogon Gerardi** var. *Gerardi* Map 353

Andropogon provincialis Lam. [P & S]

Andropogon Gerardi Vitman [G]

Throughout Missouri, except absent from the southeastern lowland section, where not known in a wild state nor recorded.

Ranges from Central America, Mexico, and Florida to Texas, north to Maine, Quebec, Ontario, Michigan, Minnesota, Manitoba, Saskatchewan, and Wyoming.

2b. **Andropogon Gerardi** var. *chrysocomus*

(Nash) Fern.

Map 353

Andropogon provincialis var. *chrysocomus* (Nash) Fern.

& Griscom [P & S]

Prairies and rocky open or waste ground.

Occurs in western Missouri south of the Missouri River in Jackson, Jasper, Newton (1 mi. east of Chris-

topher, August 18, 1953, *Palmer* 56526), and Stone counties.

Ranges from Quebec to Montana, south to Connecticut, New York, Indiana, Arkansas, Texas, and New Mexico.

Another more western variety, var. *paucipilus* (Nash) Fern., with glabrous racemes and the internodes possessing only a few weak hairs, occurs in Nebraska and Montana. It should be looked for on the loess hills of northwestern Missouri, where it may possibly be found.

Plants either glabrous or pubescent and yellow-green or silvery-glaucous occur throughout the range. Plants vary in height from usually nearly as tall or taller than the average man to individuals with secondary or late-developing culms only 5 dm. or so tall, or up to 2.5 meters. The first inflorescences, the terminal or topmost ones, of the season, usually bear 3 or more (6–12) digitate racemes; the later and lateral ones may often bear only a pair of racemes. In the beginning and during flowering time, the racemes spread apart, but after flowering and at maturity contract and become erect. The ligule is a brownish rather firm membrane 2–3 mm. high gradually rounded to subtruncate at the slightly uneven or somewhat broken margin fringed by a minute border of white hairs. Sometimes behind the ligule at the base of the upper surface of the leaf-blade are found long equal hairs arranged in a row. After frost the plants usually take on a bronze-purple or russet brown with lavender color.

Like *A. scoparius*, this grass sometimes may contribute as a causative in hay fever cases. *Andropogon Gerardi* var. *Gerardi* is of considerable value as a forage grass, and ranks near the top of the list of native grasses for the quality and quantity of its production.

3. **Andropogon ternarius** Michx. Map 354

Flowers July–October.

Prairies, along railroads, and rocky or sandy open woods or glades, especially on sandstone and chert exposures.

Occurs in southern Missouri, north to Ste. Genevieve, Phelps, Laclede, and Barton counties.

Ranges from Florida to Texas, north to New Jersey, Delaware, Maryland, Kentucky, and Missouri.

The ligule is a brownish membrane about 1 mm. high with a subtruncate summit usually fringed with tiny white hairs. A conspicuous upwardly-pointing tuft of silky white hairs surrounds the culm just below each of the upper nodes and spathes. The silky white rather stiff racemes protruding from long peduncles give this species a very distinctive and ornamental

appearance. The silky white inflorescences continue to remain on the plant well into winter.

The racemes of this species are straight and more rigid usually than in *A. Elliottii* or *A. virginicus* and terminate long erect peduncles. Occasional specimens of *A. ternarius* with more laxly-flowered or less straight racemes may be distinguished by other characters presented in the key.

4. **Andropogon virginicus L.**

Broom Sedge

Map 355

Andropogon virginicus var. *virginicus* [BB]

Andropogon virginicus var. *genuinus* Fern. & Grisc.
[P & S]

Andropogon virginicus var. *tetrastachyus* (Ell.) Hack.
[P & S]

Flowers August–November.

Occurs in prairies, glades of sandstone, chert, or granite, sandy and fallow or abandoned fields, along railroad tracks, rarely in wet open and swampy places. In southern and central Missouri north to Pike, Howard, Ray, and Cass counties; common throughout the Ozarks, southeastern lowland, and unglaciated prairie sections of the state.

Ranges from Florida to Texas and Mexico, north to Massachusetts, New York, Ohio, Indiana, Illinois, Missouri, Kansas, and Oklahoma; also West Indies and Central America.

The ligule is a yellow-brown membrane with a truncate hairy white-fringed border. It is smaller than in *A. Gerardi* and *A. scoparius*, 0.5–1 mm. long.

As in *A. scoparius*, Fernald and Griscom proposed the subdivision of *A. virginicus* into several varieties based upon the branching of the inflorescence, length of racemes, color of leaves, and pubescence of spathes. Missouri material was placed by these authors in *A. virginicus* var. *virginicus* (their var. *genuinus*) and in var. *tetrastachyus* (Ell.) Hack., the latter being separated on the basis of branching instead of simple or nearly simple inflorescence. Again, however, as in the case

of *A. scoparius*, a division of the species has not been found workable for the Missouri material. Most of the Missouri specimens can be placed in the simple type of inflorescence, which characterizes *A. virginicus* var. *virginicus*, whereas the var. *tetrastachyus* is less frequently encountered.

The occurrence of this grass usually indicates a definitely acid soil. Great masses of it are found in fallow or abandoned fields and sandy or cherty open soils. Like Little Bluestem (*A. scoparius*), the dried clumps provide a rather striking splash of russet-brown or tan color to the bare or exposed fields of the landscape during the late fall and winter months. Early American housewives of the southern states employed the culms of this grass, using them as makeshift brooms, hence the name broom-sedge. When young, the grass provides considerable forage value for livestock.

5. **Andropogon Elliottii Chapm. var. Elliottii**

Map 356

Andropogon Elliottii var. *projectus* Fern. & Grisc.
[BB, P & S]

Flowers September–November.

Occurs most frequently in acid soils derived from sandstone, chert, or granitic rocks, either on rocky glades of these substrata or in rocky open woodland or border of woodland with acid soil, sometimes also in rocky acid prairie and in sterile soils along roadsides, rarely along railroad tracks.

Found in southern and east-central Missouri, and locally north in Boone County (railroad near Providence, Missouri River, October 7, 1953, *Kucera*). Frequent in the eastern Ozark section, but absent from the western Ozarks. Absent mostly from the southeastern lowland section.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Kentucky, Ohio, Indiana, Illinois, and Missouri; also in Cuba and British Honduras.

The ligule is 0.5–1 mm. long and similar to that

of *A. virginicus* and *A. ternarius*. As in *A. ternarius*, a conspicuous tuft of long white hairs surrounds the culm just below each of the upper nodes, and is best developed at the base of the leaflike spathes.

Like *A. ternarius* and *A. saccharoides*, *A. Elliottii* is a very beautiful and ornamental species, and lends a distinct yellow-brown charm to the winter landscape with its clumps of dried leaves and culms. The writer has attempted several times to establish this species and *A. ternarius* by transplanting them to acid-soil habitats in his wildflower garden. He has not been successful with these acid-soil-inhabiting species, whereas no difficulty was experienced in transplanting and getting established plants of *A. scoparius* and *A. Gerardi*.

Andropogon Elliottii var. *projectus* was described by Fernald and Griscom in 1935 (Rh. 37: 139. 1935), based upon plants in which most of the racemes are exserted on long peduncles from the leaflike spathes. This variety is rejected by Deam (*Fl. Indiana*, p. 179. 1940), however, as merely a phase in the development of the inflorescence; apparently, Fernald himself became convinced of the artificial status of the variety, since he does not recognize it as worthy of separation in the eighth edition of *Gray's Manual*,

uniting it with typical *A. Elliottii* var. *Elliottii* by stating in the description (p. 234), 'racemes . . . included within or exserted from the large sheaths on erect peduncles.'

Andropogon Elliottii var. *Elliottii* is sometimes found in association with *A. virginicus* and *A. ternarius*, all of them thriving on acid soils.

6. *Andropogon saccharoides* Sw.

Silver Beardgrass

Map 357

Flowers July–October.

Occurs in prairies, glades, on rocky ledges, and along railroad tracks, where found scattered in southern and central Missouri north to St. Charles, Boone, and Jackson counties. The grass is native in southwestern Missouri, but is introduced elsewhere in the state.

Ranges from South America, Central America, and the West Indies to Mexico, and from Alabama, Texas, and California, north to Missouri, Kansas, Colorado, and Arizona.

The silvery-white dense, plumelike inflorescences are very showy and ornamental. The ligule is a white membrane 1–1.5 mm. high with a slightly broken subtruncate summit.

77. *Sorghum* Adans. *Sorghum*

(Also spelled *Sorgum*)

Tall grasses with long narrow or broad leaves and large panicles of 1- to 5-jointed short racemes which eventually break apart. Spikelets occur in pairs (one sessile and fertile, the other stalked and sterile or staminate) or in 3's at the ends of the branches (2 of them stalked and staminate or empty).

Plants perennial, creeping with scaly underground rhizomes; leaf-blades usually 10–20 mm. wide; panicles rather open with spreading branches; spikelets broadly lanceolate, disarticulating from the pedicel at maturity 1. *S. halepense*

Plant annual, without any creeping underground rhizomes; leaf-blades up to 75 mm. wide; panicle either open with spreading branches or dense and compact; spikelet at maturity not disarticulating from the pedicel 2. *SORGHUM* (cultivated species and varieties)

1. *Sorghum halepense* (L.) Pers.

Johnson Grass

Map 358

Also known as Egyptian Millet and by several other common names.

Flowers June–November.

Very weedy and occupying large areas in low meadows, fertile cultivated ground, along roadsides, railroad tracks, at the base of wooded slopes in thickets, and borders of cultivated fields.

Introduced and established mainly in the southern, central, and western parts of the state, north to St. Charles, Boone, Livingston, Caldwell, and Holt

counties; not recorded from the northeastern quarter of the state.

Native of Europe and Asia; introduced into the United States from Turkey about 1830. About 1840 Col. William Johnson introduced it in Alabama. It has spread from Florida and Texas north to Massachusetts, New York, Ohio, Indiana, Illinois, and Iowa; also introduced and a weed in Mexico, the West Indies, Central and South America.

The open loosely spreading inflorescence has a dull purplish or rosy-purple color tinged with green. The culms may reach 3 meters in height. The leaf-blades

have a conspicuous whitish midnerve, and a hairy-fringed ligule.

Although cultivated for forage, especially in the southern states, it becomes a troublesome weed, forming dense colonies with its creeping rhizomes and covering the ground to the exclusion of other plants. Once having invaded an area, the plant is nearly impossible to eradicate. It can be eradicated by repeated deep plowing, then allowing the ground to lie fallow, followed by cultivating with a different kind of crop. Farmers are being warned not to introduce it in cultivation for hay crop, as it can invade valuable cotton, corn, and potato fields. During its time of flowering it is suspected of causing much hay fever. After a frost, the leaves yield prussic acid, which may fatally poison cattle. A second crop is also likely to develop the poison, especially during a hot dry season. The leaves are often blotched with reddish-purple, sign of a bacterial disease, with which the plant is commonly afflicted.

2. *Sorghum* (cultivated species and varieties)

Map 359

Flowers June–October.

Commonly cultivated, and occasionally escaped from cultivation along roadsides and railroad tracks.

Various species or varieties, depending upon personal points of view, are grown in Missouri, either in experimental plots, from which they occasionally escape, or are intensively cultivated as crops.

Some of the most intensive work on the group has been done by Stapf and by Snowden. For more detailed information their works should be consulted (Stapf, *Fl. Trop. Africa* 9, pt. 1: 104–54. 1917; Snowden, J. D. Classification of the Cultivated *Sorghums*. Kew Bull. 1935: 221–55. 1935; Snowden, J. D. *The Cultivated Races of Sorghum*. 1936). They consider the cultivated *Sorghums* mostly as distinct

species, rather than treating them as varieties under *Sorghum vulgare* Pers., as had been done by some previous workers.

The following treatment is based upon the above cited works, and especially that of Snowden, the key presented intended not so much as a definitive contrastive type as ordinarily found in the other portions of this flora, but rather as a general orientation to the main types of *Sorghum* which may be expected to be seen in Missouri.

- a. Mature spikelets closed, not exposing the grain . b
 - b. Culms usually more than 6 mm. in diameter; leaf-blades mainly more than 20 mm. wide; leaf-sheaths longer than the internodes . 2f. Chicken Corn (*S. DRUMMONDII*)
 - b. Culms usually less than 6 mm. in diameter; leaf-blades mainly less than 20 mm. wide; leaf-sheaths shorter than the internodes .
 - 2g. Sudan Grass (*S. SUDANENSE*)
- a. Mature spikelets open and exposing the grain . c
 - c. Inflorescence a long much-branched loose panicle with elongated branches naked (without flowers) below, arising from a short axis; spikelets usually awned; culm stout, 3–4 meters tall, dry; grown for the branching inflorescence for brooms .
 - 2b. Broom Corn (*S. DOCHNA* var. *TECHNICUM*)
 - c. Inflorescence mostly a dense and compact panicle, sometimes loose and open, erect or recurved (peduncle goosenecked); spikelets with or without awns; culms stout, dry or juicy; grown for the sugar in the culm or forage or seeds as food for livestock and man d
 - d. Inflorescence a dense or loose panicle, erect or recurved (peduncle goosenecked); culm stout, 1.8–2 meters tall, with an abundant sweet juice; grown for the sugar and syrup in the culm and for forage. . 2a. Sorgho, Sweet Sorghum (*S. DOCHNA* var. *DOCHNA*)

- d. Inflorescence usually a dense and compact panicle; culm stout, with an acid dry or slightly juicy culm; grown mostly for the seed (grain), but also the culms and leaves grown for forage. . . . e

- e. Spikelets not awned; seeds mostly black, or red or white; inflorescence oblong or cylindrical, erect; culms with slightly juicy, acid pith. . . .

2c. Kafir Corn (*S. CAFFRORUM*)

- e. Spikelets awned or without awns; inflorescence mostly recurved (goose-necked) or erect; culms with dry pith. . . . 2d. Durra (*S. DURRA*)

- e. Spikelets awned or without awns; inflorescence erect or somewhat curving in a flexuous manner; culms with dry pith. . . . 2e. Feterita (*S. CAUDATUM* var. *FETERITA*)

2a. *Sorghum Dochna* (Forsk.) Snowden var.

Dochna Sweet Sorghum, Sorgho Map 359
Sorghum vulgare var. *saccharatum* (L.) Boerl.
S. saccharatum Moench.

Infrequently escaped from cultivation along roadsides and waste ground. Known only from a collection from Jackson County (waste ground, Courtney, September 23, 1933, *Bush* 47).

Sweet Sorghum produces culms with a sweet juicy pith from which is extracted a syrup. Sorghum molasses is a product of this syrup, and is used for flavoring pancakes, as a confectionery and ingredient in the preparation of cakes and cookies, and as a medicine. Sweet Sorghum is also grown for its forage and silage value and is extensively cultivated in Missouri.

2b. *Sorghum Dochna* var. *technicum* (Koern.)

Snowden Broom Corn Map 593
Sorghum vulgare var. *technicum* (Koern.) Jav.

Very rarely escaped from cultivation, and known as such from St. Louis County (North St. Louis freight yard of Burlington Railroad along the highway which branches on the foot of Carrie Avenue to the north, St. Louis, August 6, 1955, *Muehlenbach* 711).

The elongated panicle branches are used in the manufacture of brushes and brooms.

2c. *Sorghum caffrorum* Beauv. Kafir Corn

Map 359
Sorghum vulgare var. *caffrorum* (Thunb.) Hubb. and
Reich.

This has not yet been recorded as an escape but is widely grown in Missouri as a forage plant for its slightly juicy acid pith, and for the seeds. The Standard Blackhull Kafir with black seeds is the most commonly grown. In other parts of the world these seeds are valued for their flavor and nutritive value, which is similar to corn or maize in its composition and food value.

2d. *Sorghum Durra* Stapf Durra Map 359

Sorghum vulgare var. *Durra* (Forsk.) Hubb. & Rehder

This has been found as an escape in Jackson County (Courtney, August 19, 1933, *Bush* 12895) and was identified by Bush as *Sorghum cernuum*.

Grown for its grain. The seeds of the white durra (*Sorghum cernuum* Host var. *cernuum* [Koern.] Snowden) are a favorite poultry feed in California. In India and some parts of southwestern Asia and northern Africa, white durra is widely cultivated.

Milo corn (*Sorghum subglabrescens* Schweinf. & Aschers.) is sometimes considered a form of the durra sorghum. It is widely cultivated in Missouri.

2e. *Sorghum caudatum* Stapf var. *caudatum*

Feterita Map 359

Sorghum vulgare var. *caudatum* (Hack.) Bailey

Sorghum caudatum var. *feterita* Stapf

This is cultivated in Missouri, but has not been recorded as an escape.

2f. *Sorghum Drummondii* (Steud.) Millsp. &

Chase Chicken Corn Map 359

Sorghum vulgare var. *Drummondii* (Nees) Hitchc.

Sometimes cultivated and reported as a weed in cornfields in southern Indiana. It has an erect, dense panicle with ascending branches and small orange, oval seeds.

2g. *Sorghum sudanense* Stapf Sudan Grass

Map 359

Sorghum vulgare var. *sudanense* (Piper) Hitchc.

Commonly escaped along roadsides and waste ground, where it is scattered over the state. This is the most commonly encountered as an escape of the cultivated annual species of *Sorghum*. The flowers vary from green to purplish. It is on the increase as a forage plant, producing a crop more certain to thrive and mature in poor dry upland soils than will corn. It is being widely grown in many sections of the state.

PLATE NO. 65

The above enumerated types of cultivated *Sorghum* are those most likely to be found in Missouri in cultivation or as escapes. Others not mentioned may be cultivated or eventually found as escapes.

Considerable pollen is produced from the various cultivated *Sorghums*, and the cause of some hay fever is sometimes attributed to them. Under certain conditions, many of the cultivated *Sorghums* are able to poison livestock because of prussic acid contained in the plant. It is stated that silage made from *Sorghum*

seldom possesses sufficient poison to injure livestock.

Sorghum grain oil is obtained from the seeds of some of the *Sorghums* and found to contain two-thirds as much oil as corn oil, for which it may be used as a substitute for salad oils or as an ingredient in oleomargarine. A wax similar to that of the Carnauba (obtained from the Carnauba palm) is also obtained from the seeds. The culms of one of the African cultivated *Sorghums* is considered to be a source for pulp in papermaking.

78. *Sorghastrum* Nash

Tall perennial grasses with long narrow leaf-blades, prominently auricled leaf-sheaths, and elongate panicles. The perfect fertile spikelets are sessile at each joint of the rachis. The racemes are reduced to 2 or 3 joints, the sterile spikelets represented only by a pedicel (stalked part).

***Sorghastrum nutans* (L.) Nash** Indian Grass

Map 360

Flowers August–September.

Frequents prairies, glades, and rocky open woods; also along railroads. Found in nearly every county of Missouri, except absent from the southeastern lowland section, where not native.

Ranges from Florida to Texas and Mexico, north to Maine, Ontario, Manitoba, North Dakota, and Wyoming.

The stiffish, elongated cartilaginous brown auricles at the base of the leaf-blades are quite characteristic.

The culms are quite smooth except for the finely appressed-pubescent nodes. At first the branches of the inflorescence during the flowering period are more or less open and spreading-ascending from the main axis. After flowering, they become contracted and bend in against the main axis of the inflorescence. The fertile spikelet, without the hairs, has a rich chestnut-brown color. The hairs surrounding the fertile spikelet at first are golden brown to fulvous brown, but at late maturity and, upon drying, become grayish. This change in aging accounts for some of the color discrepancies given in descriptions of this species.

79. *Manisuris* L. Joint Grass

Glabrous perennial grasses with slender, cylindrical, cartilaginous solitary spikes breaking off from the axis at maturity. The spikelets occur in pairs in cavities at the nodes of the cylindrical jointed axis.

***Manisuris cylindrica* (Michx.) Ktze.**

Joint Grass¹

Map 361

Flowers late May–August.

Found in prairies and sandy open ground, where known only from Mississippi, Barton, and Jackson counties.

Ranges from Florida to Texas, north to South Carolina, Missouri, and Oklahoma.

The slender solitary inflorescence resembles the pistillate portion of the inflorescence of the next genus, *Tripsacum*.

Tribe XII. TRIPSACEAE

Grasses of this tribe have pithy stems, spikelets of 1-sexed flowers with the pistillate below, and the staminate toward the tip of the same inflorescence, or the staminate and pistillate flowers in separate inflorescences on the same plant (monoecious).

Plate no. 66. 1. *Tripsacum dactyloides*; a. Plant, $\times \frac{3}{8}$; b. Pair of staminate spikelets with rachis joint, $\times \frac{3}{4}$; c. Pistillate spikelet with rachis joint, $\times \frac{3}{4}$. 2. *Zea mays*; a. 2 branches of staminate inflorescence (tassel), $\times \frac{3}{8}$; b. Pistillate inflorescence (ear), $\times \frac{3}{8}$; c. Staminate spikelet, $\times \frac{1}{2}$; d. Single pistillate spikelet soon after flowering, $\times 3$; e. Pair of pistillate spikelets attached to rachis (cob) with mature grains, the second glume showing, $\times \frac{1}{2}$.

PLATE NO. 66

361 *Manisuris cylindrica* (Joint Grass)362 *Tripsacum dactyloides* (Gama Grass)363 *Zea Mays* (Corn)

80. *Tripsacum* L. Gama Grass

Rather tall stout perennials growing in large clumps with thick rhizomes, broad flat leaves, the staminate and pistillate flowers in separate parts of the same many-flowered spikes. The pistillate spikelets are solitary and occur in hollowed portions on opposite sides of the thickened hard joints of the lower part of the rachis; this pistillate portion breaks up at maturity into several 1-seeded joints. The staminate spikelets are 2-flowered and in pairs on one side of a continuous rachis.

Tripsacum dactyloides L. Gama Grass

Map 362

Flowers May–September.

Frequents prairies, open limestone slopes, borders of woods and thickets, fields, waste, and cultivated ground, and along roadsides and railroads. Scattered over the state.

Ranges from Florida to Texas and Mexico, north

to Massachusetts, New York, Michigan, Illinois, Iowa, and Nebraska.

The ligule is a short membrane with a ring of hairs.

At times hundreds of plants of this species may be present in natural prairies located in the southwestern quarter of the state, and occur in large clumps which form conspicuous patches of olive-green leaves and culms.

81. *Zea* L. Maize, Indian Corn, Corn

Robust annual grasses with long, spreading, wide leaves. The ligule is membranous with an uneven, broken-edged hairy border. The staminate spikelets are 2-flowered, in pairs on one side of a continuous rachis; the top tassel (a racemose panicle) of the plant is completely staminate. The pistillate inflorescence, borne below in the axils of the leaves, is a short-stemmed spike (ear) enveloped within numerous green spathes (husks).

The pistillate spikes consist of usually 8–30 rows of sessile spikelets surrounding a thick axis (the cob). The pistillate spikelets occur in pairs, with one fertile and one sterile floret, the glumes broad and rounded or indented (emarginate) at the summit; the long slender styles protrude from the summit of the pistillate spike-like silky threads. At maturity the grain is much longer than the glumes.

Zea Mays L. Maize, Indian Corn, Corn Map 363

Flowers June–August.

Occasionally found self-seeding itself in rich or rocky woods where unintentionally dropped or carried by man, squirrel, and other animals. Also found as waifs occasionally along roads, railroad tracks, dump heaps, and in waste ground, but not self-seeding nor showing signs of persisting.

Scattered over the state.

Native probably of South America.

The pollen of corn sometimes causes hay fever, but, fortunately, due to the large size of the pollen grains, is only to a slight extent carried around in the atmosphere.

The dried stalks of corn are sometimes used as pulp for making into cardboard.

Fam. **CYPERACEAE** (Sedge Family)

Plants resembling grasses, but the stems (culms) usually solid or sometimes hollow, often 3-angled, but also round, flattened, or 4- or more-angled. Leaves growing from base or on stem, those on stem usually in 3 ranks and with a sheath usually closed (except at summit); leaves are sometimes absent or inconspicuous because of reduced size. A ligule (scaly membrane) is usually present at the junction of leaf-sheath and leaf-blade. The either perfect or 1-sexed flowers are greatly reduced, each in the axil of a single scale or glume, which overlap into spirally arranged or 2-rowed spikelets or spikes. The perianth is lacking or composed of bristles or scale-like sepals. Stamens 3, 2, or 1. Pistil 1, with 1 style, which is 2-3-cleft, and a superior 1-celled ovary with 1 erect ovule; at maturity this pistil becomes an achene, which may be flattened, 3-sided, or rounded, and is free from the wall (pericarp) of the fruit and not attached to it.

In many instances, it will be noted that satisfactory and certain identification of the sedges is possible only with mature or fruiting plants. It is necessary, therefore, that this be kept in mind when trying to arrive at a particular identification.

Many species of this family shed an abundance of very buoyant pollen, but do not appear to be of any significance in causing hay fever.

- a. Ordinary leaves apparently not present on the plant, only the culms (stems) evident b
- b. Inflorescence of 1 spikelet at the top of the stem (culm); achenes crowned with a tubercle. 3. ELEOCHARIS
- b. Inflorescence of 2 or more spikelets, or, if only of 1 spikelet, this not at very tip of stem; achenes lacking a tubercle. 6. SCIRPUS
- a. Ordinary leaves present, either occurring at base of plant, on culm, or both c
- c. Culm (stem) hollow, jointed, terete (round when cut cross-wise), and with many, short leaf-blades; inflorescence arising from the sides of the culm in the axils of the leaf-sheaths. 2. DULICHIMUM
- c. Without the above combination of characters d
- d. Spikelets not all alike, because the staminate (male) and pistillate (female) flowers are in separate parts of the same inflorescence or in completely separated inflorescences, or the pistillate part is either (1) a pistil surrounded by a tight- or loose-fitting sac (perigynium) or (2) in fruit becomes a miniature white or buff golf-ball-shaped hard achene (fruit) e
- e. Pistillate part (spikelet) 1-flowered, becoming in fruit a miniature white or buff golf-ball-shaped hard achene (fruit) 10. SCLERIA
- e. Pistillate part (spikelet) of more than 1 flower, each pistil surrounded by a tight- or loose-fitting sac (perigynium) 11. CAREX
- d. Some or all of the flowers with stamens and pistil in the same flower (perfect), the spikelets appearing to be all alike or essentially so, or at least *none* of the pistillate flowers surrounded by a sac (perigynium) nor in fruit becoming a hard white or buff golf-ball-shaped achene f
- f. Bristles, scales, or both present at the base of each flower, sometimes only 1 minute scale present g
- g. Some bristles (hair-like) at the base of each flower h
- h. Three bristles alternate with 3 enlarged stalked scales at the base of each flower; some of the leaf-sheaths hairy with evident hairs up to 1.5 mm. long 7. FUIRENA
- h. Only the bristles present at the base of a flower; leaf-sheaths without hairs, at most somewhat roughened (scabrous) i
- i. A triangular or long-beaked extension crowns the top of the achene or ovary from which it is separated by a dividing line; only 1-2 fertile and perfect flowers in a spikelet, located at or near the top, the other flowers sterile, staminate, or imperfect 9. RHYNCHOSPORA
- i. Achene or ovary tapering directly into the summit without any extra beak or extension present marked by any line of separation; flowers all fertile and perfect and few to many. 6. SCIRPUS
- g. No bristles and only 1 minute scale present at base of each flower 8. HEMICARPHA
- f. No bristles or scales or any other attachment at base of each flower j
- j. A minute tubercle crowns the achene and is separated from it by a dividing line 4. BULBOSTYLIS
- j. No tubercle present on top of achene k
- k. Scales of spikelets in 2 ranks, alternating on 2 sides of the axis (rachis) of the spikelet, giving the spikelet a mostly flattened appearance (but immature specimens have a more terete [rounded] or less compressed appearance) 1. CYPERUS

- k. Scales of spikelets spirally arranged, shingle-like (imbricate) in several ranks, presenting a more rounded or cone-shaped appearance *l*
- l. Base of style larger than rest of style 5. *FIMBRISTYLIS*
- l. Base of style slender, not larger than rest of style *m*
- m. Spikelets more or less cone- or almost ball-shaped, broadest at the base or near the middle, $1\frac{1}{2}$ –4 times as long as broad, 1–2.5 mm. wide, well-rounded from all sides; spikelets many-flowered 6. *SCIRPUS*
- m. Spikelets long and narrow (linear-lanceolate or subulate), either conspicuously much longer than broad and 4–15 times longer than broad, of nearly the same width throughout, or, if only $2\frac{1}{2}$ –3 times longer than broad, then the spikelets 1–3-flowered 1. *CYPERUS*

1. *Cyperus* L. Umbrella Sedge

Annual or perennial plants with usually triangular culms. Leaves mostly crowded at the base, with 1 or more at the summit of the culm at the base of the umbel-like spikes or heads forming the inflorescence. Spikelets 1–many-flowered, either more or less flattened with the scales 2-ranked, or narrowly cylindrical (terete) or 4-angled. Flowers perfect, without a perianth. Stamens 1–3. Styles 2–3-cleft. Achenes lenticular (flattened with 2 convex surfaces) or triangular.

The references to Kükenthal in this section refer to his recent treatment of the genus (Das Pflanzenreich IV: 20. Heft. 101. Nov. 1956).

- a. Scales of spikelets narrowed at tip into a conspicuous outwardly curved awn $1/3$ – $3/8$ total length of scale; dried plants or bruised fresh ones giving off an odor of Slippery Elm (*Ulmus rubra*). 5. *C. ARISTATUS*
- a. Without the above combination of characters *b*
- b. Style split into 2 thread-like divisions; achene or ovary lenticular (rather flattened with 2 convex surfaces or with 2 sides or 2 angles) *c*
- c. Flower only 1 in each spikelet; spikelets only slightly longer (2–3 times) than broad. 26. *C. TENUIFOLIUS*
- c. Flowers many (6–35) in each spikelet; spikelets conspicuously longer (4–15 times) than broad *d*
- d. Scales of spikelet yellow, greenish, yellow-green, or yellow-brown *e*
- e. Spikelets mainly 1–1.9 mm. wide; tips of the scales of spikelets very slightly pointed (mucronulate), prolonged, and projecting slightly from the next scale above. 4. *C. POLYSTACHYOS*
var. *TEXENSIS*
- e. Spikelets mainly 2–3 mm. wide; tips of the scales of spikelets blunt (obtuse), closely appressed to the next scale above.
- f. Mature achene (seed-like fruit) black, with the cells on the surface (superficial) of a rectangular-oblong shape longer than broad (use magnifying lens of over 15 ×)
1. *C. FLAVESCENS*
- f. Mature achene brownish or grayish with the cells on the surface 4–5-sided and of about the same diameter throughout (use magnifying lens of over 15 ×) . 3b. *C. RIVULARIS*
var. *RIVULARIS* f. *ELUTUS*
- d. Scales of spikelet tinged more or less with red-purple, brown-purple, reddish-brown, or mahogany-chestnut-brown *g*
- g. Style cleft nearly to its base; branches of styles protruding 2–4 mm. beyond scale, usually many of such and remaining attached after flowering; scales of spikelet mainly 2.5–2.7 mm. long, rather loosely overlapping and causing base of achene to be visible in dried specimens 2. *C. DIANDRUS*
- g. Style cleft only to about the middle; branches of style protruding mainly 1–1.5 mm. beyond scale, usually few of such and soon falling after flowering or easily falling with the touch of a dissecting needle; scales of spikelet mainly 2–2.4 mm. long, closely overlapping to cause the achenes to be hidden . . . 3a. *C. RIVULARIS* var. *RIVULARIS* f. *RIVULARIS*
- b. Style split into 3 thread-like divisions; achene or ovary 3-sided (trigonal) *h*
- h. Scales of spikelet purple-red, reddish-tinged, brown-purple, or reddish-brown *i*
- i. Tip of scale not reaching the base of the next scale above it on the same side, the scales not overlapping, exposing part of the zig-zag joints of the axis of the rachis at flowering time
13. *C. ENGELMANNI*
- i. Tip of each scale reaching the middle or almost the middle of the next scale above it on the same side, the scales prominently overlapping, the axis of the rachis not exposed at flowering time *j*
- j. Scales of spikelet 1–1.5 mm. long; achene 0.8–1 mm. long, grayish-white . . . 9. *C. ERYTHRORHIZOS*

- j. Scales of spikelet mainly 2-4 (rarely 1.5) mm. long; achene 1-2 mm. long (measure mature ones only), golden brown, gray-brown, pale brown, reddish-brown, or blackish *k*
- k. Scales of spikelet mainly 2-2.9 mm. long, conspicuously nerved, loosely overlapping; spikelets 1-2 mm. wide; achenes gray-brown, pale brown, golden-brown, or reddish-brown; annuals without runners at base, or perennials with weak scaly runners (stolons) *l*
 - l. Annuals with numerous fine roots; scales of spikelets dark reddish- or mahogany-brown; spikelets crowded or densely clustered, in age each joint of the rachilla breaking up into separate segments between the scales; scales at extreme tip of spikelet prominently narrowed to give the spikelet a long-pointed or acuminate summit 12. *C. FERRUGINESCENS*
 - l. Perennials with slender underground scaly runners (stolons) with sometimes a tuber at the end (careful examination should show at least some sign of a scaly runner, which is usually visible among the finer roots); scales of spikelets with some light reddish-brown, otherwise yellow- to golden-brown; spikelets not crowded or densely massed, with noticeable spacing between spikelets, in age the joints of the rachilla not breaking up into segments, but remaining intact; scales at extreme tip of the spikelet slightly narrowed, but not giving the spikelet a long-pointed or acuminate summit 17. *C. ESCULENTUS*
- k. Scales of spikelet mainly 3-4 mm. long (rarely less than 3), faintly nerved or without nerves, closely overlapping and the tips appressed to adjacent scales; spikelets about 2 mm. wide; achenes blackish; perennials sending out firm tough horizontal runners from the base of the plant *m*
- m. Most of the leaf-like bracts of the involucre (at base of inflorescence) longer than the rays (branches) of the inflorescence; runners at the base of plant stout, forming a new horizontal underground stem from their tip; scales of spikelet mainly 3.8-4 mm. long 15. *C. SETIGERUS*
- m. Most of the leaf-like bracts of the involucre shorter than or equaling the rays of the inflorescence; runners thread-like, usually ending in little enlargements (tubers); scales of spikelet mainly 2.5-3.5 mm. long 14. *C. ROTUNDUS*
- h. Scales of spikelet mainly brown, yellow, green, straw-color, golden brown, gray-brown, greenish-white, or combinations of these shades *n*
- n. At least some part of the culm (stem) rough to the touch or minutely pubescent *o*
 - o. Spikelets flattened in appearance, 1.5-4.5 mm. wide, spreading to ascending (except the lowermost ones of a spike), not crowded and not conspicuously turned down (reflexed); spikelets mainly 5-16-flowered (up to 20), mainly 10-25 mm. long; scales of spikelet 3.5-4.5 mm. long, with conspicuous awns *p*
 - p. Spikelets pinnately or racemously arranged and ascending; scales with an acuminate tip or the midrib prolonged to 1 mm. long; achenes 2.5-3.5 mm. long 22. *C. SCHWEINITZII*
 - p. Spikelets digitately arranged or giving that appearance, the axis very shortened, mainly spreading or somewhat ascending; scales more rounded, blunt, or with a midrib prolonged 0.3-0.5 mm. long; achenes 2.2-2.5 mm. long 22a. *C. × MESOCHORUS*
(*C. Schweinitzii* × *C. filiculmis*)
 - o. Spikelets subulate, not flattened, about 1 mm. wide, all except the uppermost conspicuously pointing down or turned down (reflexed) at maturity, thickly crowded in an obovoid or obconic head; spikelets 1-3-flowered, 3-11 mm. long; scales of spikelets not as above. *q*
 - q. Rays (branches) of inflorescence rough (scabrous); leaves of involucre (at base of inflorescence) rough; heads (inflorescences) obconic, noticeably narrowed at the base; spikelets sharp-pointed (pungent) 21. *C. PLUKENETII*
 - q. Rays of inflorescence smooth; leaves of involucre glabrous; heads more or less cylindrical or slightly obovoid; spikelets not sharp-pointed 20. *C. DIPSACIFORMIS*
- n. Culm (stem) smooth *r*
- r. Inflorescence resembling in shape a ball or globe (spherical) or the fingers on a hand (digitate), the spikelets crowded together or all arising on a shortened axis which is 1 cm. or less long, or at least not conspicuously pinnately or racemously arranged on the axis. *s*
- s. Spikelets distinctly flat, the scales in 2 ranks alternating on 2 sides of the axis (rachis) of the spikelet, or, if not appearing flat, then the achenes linear and only 1-1.2 mm. long; achenes 0.9-1.5 mm. long; spikelets mainly 6-40-flowered; annuals, or, if perennials, without corm-like bases (like small knots or enlargements) *t*
- t. Scales of spikelets conspicuously 9-13-nerved, mainly 2.5-3 mm. long, striped white and yellow with a prominent green midrib; midrib of scale prolonged as a straight projection; inflorescence resembling the fingers on a hand (digitate), the spikelets spreading from nearly the same point of the shortened axis; spikelets 8-25 mm. long 6. *C. COMPRESSUS*

- t. Scales of spikelets 3-5-nerved near midnerve, mainly 1.8-2.1 mm. long, at first rather uniformly pale greenish-white or pale greenish, in age tinged brown; tip of scale slightly curved outward; inflorescence globe-shaped or of compact ball-like masses; spikelets 3-10 mm. long u
- u. Robust perennial, 3-7.5 dm. tall; culm (stem) mainly 2-4 mm. wide in lower half; achene linear, about the same width from one end to the other, 4-6 times as long as wide; scales of spikelet narrowly oblong, closely touching each other, their tips very slightly curved outward or ascending, the numerous spikelets bunched into thick, crowded, compact, often large heads 7. *C. VIRENS*
- u. Slender annual, mainly 0.5-3.5 dm. tall; culm (stem) mainly 0.5-1.5 mm. wide in lower half; achene oblong or ellipsoid, tapering at each end and broadest near the middle, 2-3 times as long as wide; scales of spikelet ovate, more loosely arranged, showing more space between each flower, the tips more widely curved out, the fewer spikelets grouped into thinner, less compact, smaller heads 8. *C. ACUMINATUS*
- s. Spikelets either rather cylindrical with somewhat curved or angled sides and not presenting a flat appearance, or, if appearing flat, then the achenes 1.5-2.5 mm. long or the spikelets 2.5-4 mm. wide; spikelets 2-8-flowered (or up to 12-20 in *C. filiculmis* and *C. × mesochorus*); perennials often with hardened corms (like small knots or enlargements) at base v
- v. Spikelets averaging 10-20 to an inflorescence, mainly 2.5-4.5 mm. wide, often appearing flat; scales of spikelets loose or with loose or spreading tips, not with tips closely appressed; spikelets 2-20-(mainly 6-16)-flowered w
- w. Leafy bracts of inflorescence widely spreading or recurved; culms 0.5-1 mm. in diameter below the inflorescence; scales 1.8-3.5 mm. long, blunt or the uppermost acutely pointed; achenes 1.5-2.3 mm. long; leaves usually less than 2 mm. wide; inflorescence a dense spherical or somewhat globose head, with or without a few short rays 23. *C. FILICULMIS*
- w. Leafy bracts of inflorescence erect or ascending; culms mainly more than 1 mm. in diameter below the inflorescence; scales 3.5-4 mm. long, with conspicuous mucros or protruding tips 0.3-0.5 mm. long; achenes 2.2-2.5 mm. long; leaves usually 2-3.5 mm. wide; inflorescence with spikelets digitately arranged, some or most of them on elongated, well-developed rays 22a. *C. × MESOCHORUS* (see also under *C. Schweinitzii*)
- v. Spikelets averaging 20-120 or more to an inflorescence, mainly 1-1.5 mm. wide, with rather rounded, curving sides or 4-angular; scales of spikelet with tips appressed to the adjacent spikelets, closely overlapping; spikelets 2-6-flowered x
- x. Spikelets 3-6-flowered; spikelets 20-40 in a loose rather globe-shaped (subglobose) to somewhat cylindrical head, with noticeable space between the fewer spikelets; scales of spikelets 2.5-3 mm. long; no hard corm-like developments at base of culm 24. *C. GLOBULOSUS*
- x. Spikelets 2-3-flowered; spikelets 80-120 or more, crowded together into a dense globe-shaped head about as long as wide or slightly longer than wide, with little space between the crowded spikelets; scales of spikelet 3.5-4.2 mm. long; hard enlargements (corm-like or tuberous) at base of culm 25. *C. OVULARIS*
- r. Inflorescence of a broadly cylindrical, obovoid, or ellipsoid shape, with the spikelets arising from a rather elongated axis mostly 1-3 cm. long, or if the axis is shorter than 1 cm., then arranged racemously (feather- or stepladder-like) (plants normally to be keyed out in this section may sometimes have a more contracted and somewhat ball- or globe-shaped inflorescence as described in the alternate r. section, but should be keyed out here)
- y. Scales of spikelets 1-1.6 mm. long, obovate, and wider than long when flattened; achenes 1 mm. long, black or blackish; axis (rachilla) of spikelet without any wings 10. *C. IRIA*
- y. Scales of spikelets 2-6 mm. long, oblong, oblong-lanceolate, or ovate, longer than wide; achenes mainly 1.2-3 mm. long, gray, brown, or black; axis (rachilla) of spikelet with wings z
- z. Most of the spikelets or at least the lower spikelets turned down (reflexed) or pointing downward, with rounded or curving sides in cross-section, not flattened; scales with 9-11 nerves (including midnerve); achenes mainly 2-3 mm. long; perennials with base of culm (stem) with hard knotty enlargements (corm-like or tuber-like) I
- 1. Spikelets rather distant from each other on the axis (rachis) of inflorescence, open spaces plainly visible between the spikelets, dull greenish, 10-30 mm. long; achenes 2.5-3 mm. long. 18. *C. REFRACTUS*
- 1. Spikelets very crowded and close to each other on the axis (rachis) of inflorescence, scarcely any or no space visible between the spikelets, yellow-brown to brownish, or mixed with gray-green, mainly 7-10 mm. (up to 15) long; achenes 2-2.5 mm. long 19. *C. LANCASTRIENSIS*

364 *Cyperus flavescentis* var. *poaeformis*

365 *Cyperus diandrus*

366 o *Cyperus rivularis* var. *rivularis* f. *rivularis*
366 □ *Cyperus rivularis* var. *rivularis* f. *elutus*

- z. Most of the spikelets ascending to horizontally spreading, the lowest sometimes turned down, usually more or less flattened in mature specimens, (if not flattened, then not having the other characters given in the alternate z. section above); most of the scales usually with 5-7 nerves (including mid-nerve) or nerveless; achenes mainly 1.2-2 mm. long; annuals, or, if perennials, the base of culm sending out slender or stout stolons (runners), or if hard and enlarged (as in *C. strigosus*), then without the other characters given in the alternate z. section above 2
2. Scales of spikelets rather distant from each other, the tip of a scale not reaching the base of the next scale located above on the same side, the joints of the axis of the spikelet exposed and appearing zig-zag 13. *C. ENGELMANNI*
2. Scales of spikelets close together, overlapping, the tip of a scale reaching up past the base of the next scale located above on the same side, the joints of the axis of the spikelet mostly hidden 3
3. Scales of spikelets chiefly yellow, greenish-yellow, golden-brown, or straw-color; in age the joints of the rachilla do not break up into separate segments, but remain as a whole intact, in place; perennial plants either with a hard enlarged corm-like base or sending out slender or stout stolons (creeping runners) 4
4. Scales of spikelets mainly 3-4.5 mm. long, conspicuously keeled (with a sharp ridge running down the back or center); base of culm (stem) either with a hardened corm-like enlargement or sending out thick underground stolons (runners) 5
5. Common plants throughout Missouri; scales of spikelets linear- to oblong-lanceolate, conspicuously nerved, loosely overlapping; achenes brown, linear; base of culm (stem) with a hard enlarged corm-like development 17. *C. STRIGOSUS*
5. Rare species known only from Jackson County, western Mo.; scales of spikelet elliptic to ovate, faintly nerved or without nerves, closely overlapping and appressed to one another; achenes blackish, oblong; base of culm sending out thick underground stolons (runners) 15. *C. SETIGERUS*
4. Scales of spikelets mainly 2-2.9 mm. long, faintly or not strongly keeled; base of culm sending out slender underground scaly stolons, sometimes bearing a tuber at the end (careful examination should show at least some sign of a scaly runner, if no tuber is present) 16. *C. ESCULENTUS*
3. Scales of spikelets dull or dark brown; in age each joint of the rachilla breaks up into separate segments between the scales; annual plants with fibrous roots, the base of culm (stem) without stolons (runners) or without a hardened corm-like enlargement 6
6. Scales of spikelet 2-3.5 mm. long, firm or coriaceous (leather-like); achene 1.5-2 mm. long; rare species, known only from the southeastern lowland section 11. *C. ODORATUS*
6. Scales of spikelet 1.5-2.3 mm. long, soft membranaceous; achene 1-1.5 mm. long 12. *C. FERRUGINESCENS*

1. *Cyperus flavescentis* L., var. *poaeformis*
(Pursh) Fern. Map 364
Cyperus flavescentis [of P & S, BB]
Flowers July-October.
Moist open sandy or gravelly ground along streams

and spring branches, ditches along roadsides and rail-road embankments, and wet places in meadows. Southern and central Missouri north to St. Louis and Boone (*Link 328*) counties, west to Polk, Dade, and Lawrence counties.

367 *Cyperus polystachyos* var. *texensis*368 *Cyperus aristatus*369 *Cyperus compressus* (Coco Grass)

Ranges from Florida to Texas, north to New York, Pennsylvania, Ohio, Michigan, Illinois, Missouri, and Kansas; also West Indies.

Fernald's interpretation of the species is followed here, var. *flavescens* ranging in Africa and Eurasia, and var. *picens* (Liebm.) Fern. from Mexico to Central America and South America.

The black achenes at maturity have transverse ridges coated with lines of a frosty white substance.

2. ***Cyperus diandrus* Torr.** Map 365
Flowers June–October.

Occurs in swampy meadows and low ground along streams and sloughs. Scattered in southern and central Missouri northeast to Marion County.

Ranges from Quebec and Maine to Ontario, Minnesota and North Dakota, south to South Carolina, Indiana, and Missouri.

Of the three related annual species (*C. flavescens* var. *poaeformis*, *C. diandrus*, and *C. rivularis*) which resemble one another, this is the most infrequently collected.

3a. ***Cyperus rivularis* Kunth var. *rivularis***
f. *rivularis* Map 366
Cyperus rivularis Kunth [G, BB, P & S]
Flowers July–October.

Occurs in swampy meadows, wet open sandy, gravelly, or muddy bars along streams and spring branches, and moist places on limestone ledges along creeks.

Ranges from Maine and Quebec to Minnesota, Nebraska, and California, south to Georgia, Texas, and Mexico.

3b. ***Cyperus rivularis* var. *rivularis* f. *elutus***
(C. B. Clarke) Kükenth. Map 366
This form with the scales greenish or only straw-

colored, instead of tinged with purplish or purple-brown as in f. *rivularis*, is known from Cedar County (gravel bar by ford along Little Sac River, T34N, R26W, south part of sect. 26, 4½–5 mi. southeast of Stockton, October 17, 1957, *Steyermark* 85774).

Another variety, *C. rivularis* var. *lagunetto* (Steud.) O'Neill, with 2–3 stamens instead of 2 as in var. *rivularis*, is found in Central and South America.

4. ***Cyperus polystachyos* Rottb., var. *texensis***
(Torr.) Fern. Map 367

Cyperus Gatesii Torr. [P & S]

Cyperus polystachyos var. *leptostachyus* Boeck. [Kükenth.]

Flowers July–October.

Occurs in wet sands and along sandy spring branches in the Crowley Ridge section of southeastern Missouri, where known only from Stoddard (along spring branch in alder thickets, at junction of flood plain and Crowley Ridge, T25N, R11E, sect. 6, 3¼ miles southeast of Bloomfield, August 20, 1954, *Steyermark* 76819) and Dunklin (wet sands, Campbell, September 9, 1910, *Bush* 6299; Milltown, Kennett, August 20, 1897, *Trelease*) counties.

Ranges from Florida to Texas and Mexico, north along the coast to Massachusetts and inland to southeastern Missouri; also in the West Indies, Central and South America, and the Philippines. *Cyperus polystachyos* var. *polystachyos* occurs in the West Indies, Mexico, Central and South America.

5. ***Cyperus aristatus* Rottb.** Map 368

Cyperus inflexus Muhl. [G, P & S]

Cyperus aristatus var. *inflexus* (Muhl.) Kük. [Kükenth.]

Flowers late May–October.

Occurs commonly on moist sand, mud, and gravel

8
PLATE NO. 67

370 *Cyperus virens*371 *Cyperus acuminatus*372 *Cyperus erythrorhizos*

bars along streams, wet depressions in rocky glades, wet places in prairies, on dry openings of ridge of upland slopes, and in alluvial and moist cultivated ground.

Most common in southern and central Missouri, extending north locally to Clark, Putnam, Daviess, and Holt counties. Apparently absent from most of northwestern and extreme southeastern Missouri.

Ranges from South and Central America, the West Indies, and Mexico north in North America to Maine, Quebec, Ontario, Michigan, Minnesota, Manitoba, Saskatchewan, and British Columbia; also Old World tropics.

The odor of slippery elm is a characteristic of dried or freshly bruised plants of this species.

6. ***Cyperus compressus* L.** Coco Grass Map 369
Flowers August–October.

Known only from wet fields and swampy ground in the southeastern lowland section (Dunklin and Butler counties) and locally north to St. Louis County.

Ranges from South and Central America, the West Indies, and Mexico, into the United States north from Florida to Delaware, west to Texas, and north in the interior to southeast Missouri, introduced elsewhere north in the United States to Minnesota and New York.

7. ***Cyperus virens* Michx.** Map 370
Cyperus pseudovegetus Steud. [BB, P & S]
Flowers late June–October.

Occurs in wet prairies, margins of streams and ponds, swales and swampy ground, along wet ditches and railroad cuts, and sandy openings in upland woods.

Mainly in the southern third of the state north to Cape Girardeau, Phelps, Laclede, St. Clair, and Vernon counties, where most common in the southeastern lowland and unglaciated prairie sections. Recorded locally northward in Boone County.

Ranges from Florida to Texas, north to New Jersey, Indiana, Illinois, Missouri, and Kansas; also in Mexico, the West Indies, Central and South America.

This species averages much more robust with taller culms and denser and usually larger heads of spikelets than *C. acuminatus* Torr. & Hook.

8. ***Cyperus acuminatus* Torr. & Hook.** Map 371
Cyperus virens var. *arenicola* (Boeckeler) Shinnery [Shinnery]

Flowers late June–October.

Occurs along muddy wet margins of ponds, creeks, spring branches, wet cultivated and alluvial ground, and open moist places. Throughout Missouri, but absent from almost a third of the counties in the state.

Ranges from Florida to Texas, north to Virginia, Ohio, Indiana, Illinois, Minnesota, and North Dakota; also in Washington and Oregon.

9. ***Cyperus erythrorhizos* Muhl.** Map 372
Cyperus erythrorhizos var. *Halei* (Torr.) Kük. [Kükenthal]

Flowers August–October.

Occurs on moist muddy margins of mud flats, banks, and alluvial ground of the larger streams, margins of sloughs, oxbow and other lakes, and rarely in wet woods. Common along the Missouri, Mississippi, Grand, and Osage rivers; elsewhere in the state absent or local; absent from the main part of the Ozark section.

Ranges from Florida to California, north to Massachusetts, New York, Ontario, Michigan, Wisconsin, Minnesota, North Dakota, Wyoming, and Washington.

This is a common inhabitant of the Missouri, Mississippi, and Grand River flood plain, where it frequents the shifting, flooded mud flats associated with other species, such as *Cyperus ferruginescens*, *Rumex maritimus* var. *fueginus*, *Euphorbia serpens*, *Bidens cernua*,

373 *Cyperus Iria*374 *Cyperus odoratus*375 *Cyperus ferruginescens*

and others, which are adapted to this type of environment.

The narrow spikelets, small reddish-brown scales, and small achenes easily distinguish this species from *C. ferruginescens*, *C. odoratus*, or other members of the genus with which it has sometimes been confused.

10. *Cyperus Iria* L.

Map 373

Flowers July–October.

Occurs in low ground and damp fallow cultivated ground in the southeastern Missouri lowlands, where known from Butler ($\frac{1}{4}$ mi. south of Ash Hill, October 29, 1956, *Steyermark 83324*) and Pemiscot ($3\frac{1}{2}$ mi. southwest of Portageville, August 19, 1955, *Steyermark 79452*) counties.

Native in Eurasia; introduced into the United States, ranging from Florida to Texas, north to Virginia and southeastern Missouri.

11. *Cyperus odoratus* L.

Map 374

Cyperus ferax Rich. [P & S, BB, Kükenthal]

Flowers August–October.

Occurs on alluvial and wet muddy flats along the Mississippi and St. Francis rivers in Pemiscot and Dunklin (Kennett, September 18, 1893, *Bush*) counties.

Ranges from Mexico, the West Indies, Central and South America, north in the United States to Massachusetts, also in the Old World tropics.

12. *Cyperus ferruginescens* Boeckl.

Map 375

Cyperus odoratus in part [BB], not L.

Cyperus ferax subsp. *speciosus* (Vahl) Kük. [Kükenthal]

Cyperus ferax subsp. *speciosus* var. *squarrosus* (Britton) Kük. [Kükenthal]

Cyperus ferax subsp. *speciosus* var. *squarrosus* f. *parvus* (Boeckl.) Kük. [Kükenthal]

Cyperus speciosus var. *squarrosus* Britton.

Flowers August–October.

Occurs on moist muddy margins of mud flats, banks, and alluvial ground of the larger streams, and margins of sloughs, oxbow and other lakes, and occasionally along railroads. Common along the Mississippi, Missouri, and Osage rivers and tributaries, infrequent or absent elsewhere in the state. Unknown from much of northern Missouri and Ozark section.

Ranges from Connecticut, New York, and Ontario to Oregon, south to Virginia, Alabama, Louisiana, Texas, Arizona, and California.

Cyperus ferruginescens is often associated on the mud flats of the larger rivers with *Cyperus erythrorhizos* and other inhabitants of wet open mud. *Cyperus ferruginescens* varies, as do other wet-mud-inhabiting species, subjected to varying flood stages of river, in height of plant, length of leaves of culms and involucre, in length of spikelets, and development of inflorescence. The inflorescence has a characteristic reddish-brown to mahogany-brown or even orange-brown color with a dense cluster of spikelets.

This species has been most often confused with *C. odoratus*, *C. esculentus*, and *C. erythrorhizos*. It is easily distinguished from *C. erythrorhizos* by the larger scales and achenes, and from *C. odoratus* by the smaller golden- or orange-brown, instead of gray or blackish achenes, and by the thinner, smaller, reddish-brown scales, instead of the dull dark or arab brown ones of *C. odoratus*. The characters used in the present key distinguish *C. ferruginescens* from *C. esculentus*.

In his recent treatment of *Cyperus*, Kükenthal (Pflanzenreich IV: 20. Heft 101. p. 620. 1956) includes Missouri or cites specimens from Missouri under *C. ferax* subsp. *speciosus* var. *squarrosus* (St. Louis, *Engelmann*) and *C. ferax* subsp. *speciosus* var. *squarrosus* f. *parvus* (St. Louis, *Riehl 67*). As shown by Fernald (Rh. 37: 150. 1935) *C. parvus* Boeckl. is only a depauperate growth state of the common *C. ferruginescens*. Likewise, Kükenthal's segregate varieties and forms

376 *Cyperus rotundus* (Nut Grass)377 *Cyperus setigerus*378 • *Cyperus esculentus* var. *esculentus* f. *esculentus*
(Yellow Nut Grass)378 □ *Cyperus esculentus* var. *esculentus* f. *angustispicatus*

above cited are considered in the present work as synonymous with *C. ferruginescens*.

13. ***Cyperus Engelmanni* Steud.**

See excluded species.

14. ***Cyperus rotundus* L.** Nut Grass, Coco Grass

Map 376

Flowers August–October.

Known only from Dunklin County in the southeastern Missouri lowland section (cultivated field near Senath, April 28, 1942, *Bratton Wallace*).

Native of Eurasia; introduced into the United States, ranging from Florida to Texas and Mexico, north to Virginia, New York, Tennessee, southeastern Missouri, and Arkansas; also on the Pacific Coast, the West Indies, Central and South America.

Although the single Missouri collection is represented only by a specimen in the vegetative state, the ellipsoid tubers and short leafy tufts are characteristic marks of the species. Undoubtedly, additional plants will be found with a more intensive search in the southeastern lowland section of the state.

Kükenthal records this species from Kansas and Missouri (*Das Pflanzenreich* IV: 20. Heft 101. p. 111. 1956).

The small underground tubers of this are used for food in the same manner as those of *C. esculentus* (which see below).

15. ***Cyperus setigerus* Torr. & Hook.** Map 377

Cyperus Hallii Britt. [P & S]

Cyperus setigerus var. *Hallii* (Britton) Kük. [Kükenthal]

Flowers June–September.

Occurs on the sandy alluvial flats of the Missouri River, where known only from Jackson County in

western Missouri (sandy bottoms, Sheffield, June 17, 1915, *Bush 7644*).

Ranges from Missouri and Kansas to Texas and New Mexico.

16. ***Cyperus esculentus* L.**

Yellow Nut Grass

Map 378

Flowers mid-June to October.

Occurs in wet open fields and cultivated ground, sand and gravel bars along streams, borders of artificial and natural lakes, swales in prairies, along railroads, and occasionally swales in woodland. Common throughout Missouri.

Ranges from Mexico, the West Indies, Central and South America, north in North America from Florida, Texas, and Arizona to Nova Scotia, Quebec, Ontario, Manitoba, and Washington; also in the Old World.

This species sometimes is thought to cause hay fever, but there has been no substantial evidence for this.

Missouri material may be divided as follows:

Spikelets 0.5–1.5 cm. long, obtuse at tip

16a. *C. ESCULENTUS* var. *ESCULENTUS* f. *ESCULENTUS*

Spikelets 1.5–3 cm. long, narrowed to an acute tip .

16b. *C. ESCULENTUS* var. *ESCULENTUS*
f. *ANGUSTISPICATUS*

16a. ***Cyperus esculentus* var. *esculentus***

f. ***esculentus***

Map 378

Cyperus esculentus L. [G, BB, P & S]

This is widespread and common throughout the state.

16b. ***Cyperus esculentus* var. *esculentus***

f. ***angustispicatus*** (Britt.) Fern. Map 378

Cyperus esculentus var. *angustispicatus* Britton [P & S]

Cyperus esculentus var. *leptostachyus* Boeckl. [Kükenthal]

PLATE NO. 68

379 • *Cyperus strigosus* var. *strigosus*
 379 □ *Cyperus strigosus* var. *robustior*

380 *Cyperus refractus*

381 *Cyperus lancastricensis*

Scattered in the state.

Another form, *C. esculentus* var. *esculentus* f. *macrostachys* (Boeckl.) Fern., differing in having the spikelets 2–3 cm. long, round-tipped, and 2–3 mm. wide, instead of 1.5–2 mm. as in the other two forms, has not been recorded from Missouri, but is to be expected.

A cultivated variety of this species, originating from Africa, *C. esculentus* var. *sativus* Boeckl., known as Chufa, with enlarged tubers at the ends of short underground runners, is sometimes cultivated in the southern United States for the sweetish nutty flesh found in the tubers. The tubers can be eaten raw, boiled, candied, or ground into a flour. In Europe the tubers have found use as a sweetmeat, conserve, refreshing sweet drink, and in historical times as a coffee substitute.

Cyperus esculentus is sometimes confused with *C. strigosus*, *C. erythrorhizos*, and *C. ferruginescens*. From *C. erythrorhizos* it differs in the longer yellow- or golden-brown scales, longer achenes, and perennial habit with the scaly runners evident. From *C. strigosus*, in addition to the usual characters of the scaly stolons and smaller scales of the spikelets of *C. esculentus* which are not deciduous from the rachis of the spike, there are additional recognition characters not stressed in the current manuals, and these have been found to be of use as follows: in *C. esculentus* most of the spikelets are separated by a space of 1–2 mm. along the rachis, and the rachis is frequently pubescent, whereas in *C. strigosus* most of the spikelets are much closer together and separated by a space of only 0.2–0.5 mm. along the rachis, which is glabrous; also, the spikelets in *C. esculentus* are relatively fewer per inflorescence than in *C. strigosus*.

17. *Cyperus strigosus* L.

Map 379

Flowers mid-June to October.

Occurs in alluvial soils of sand, gravel, and mud along streams, borders of lakes and sloughs, roadside ditches, prairie swales, moist open ground in fallow

or cultivated areas, and along railroads. Found throughout Missouri.

Missouri material may be separated into two varieties:

- Spikelets 4–14-flowered, 0.5–1.8 cm. long
- 17a. *C. STRIGOSUS* var. *STRIGOSUS*
- Spikelets 12–25-flowered, 2–3 cm. long
- 17b. *C. STRIGOSUS* var. *ROBUSTIOR*

17a. *Cyperus strigosus* var. *strigosus* Map 379

Cyperus strigosus L. [G, BB, P & S]

Cyperus strigosus f. *compositus* (Britton) Kük. [Kükenthal]

Cyperus strigosus var. *elongatus* (Torr.) Britton

Cyperus strigosus var. *capitatus* Britton

This is the common type found throughout the state.

Ranges from Florida to Texas and New Mexico, north to Maine, Quebec, Ontario, Michigan, Wisconsin, Minnesota, and South Dakota; also in the Pacific states.

17b. *Cyperus strigosus* var. *robustior* Britt.

Map 379

Cyperus strigosus f. *robustior* (Kunth) Kük. [Kükenthal]

Occurs in a few widely scattered localities, but probably of more frequent occurrence.

Ranges from Florida to Mississippi, north to Massachusetts, Connecticut, New York, West Virginia, Indiana, and Missouri.

Of the several named varieties and forms that have been recorded under *C. strigosus*, Fernald and Griscom (Rh. 37: 150–51. 1935) retain var. *robustior* and var. *stenolepis* (Torr.) Kük. as good varieties. Father O'Neill (Rh. 44: 79–81. 1942) favors the maintenance of var. *stenolepis* but would reduce var. *robustior* and other varieties and forms to synonymy. He also argues that a range of intergrading forms can be found

382 *Cyperus dipsaciformis*383 *Cyperus Plukenetii*384 • *Cyperus Schweinitzii*
384 □ *Cyperus X mesochorus* (*C. Schweinitzii* X *C. filiculmis*)

varying from simple inflorescences, where a plant is crowded by others close by, to compound inflorescences (characteristic of *f. compositus*) where a plant is by itself in the open and in better soil. On the basis of the more compound inflorescence, the collections of *Bush* from Oregon Co. in 1892, and *Bush* 6175 would be determined as *C. strigosus f. compositus*. However, O'Neill believes there is no way to separate such specimens having slightly compound inflorescences (Engelmann, St. Louis in 1845) classified by Britton as *C. strigosus var. robustior*, from others with more compound inflorescences of *f. compositus*.

In the present treatment the var. *robustior* is being retained tentatively as a geographical variety, according to Fernald and Griscom's studies, until more experimental evidence is forthcoming to prove that these variations are governed by environmental conditions and do not have any genetic value.

18. *Cyperus refractus* Engelm. Map 380
Flowers August–September.

Occurs along gravel bars of streams, dry sandy or sterile open woodland of valleys, and low ground following streams. Southern and east-central Missouri, confined to the Ozark section, north to St. Louis and Osage counties, west to Pulaski, Douglas, and Barry counties.

Ranges from New Jersey to Ohio and Kentucky, south to Georgia, Alabama, Tennessee, Missouri, and Arkansas.

The rather long, slender, rather remote, pale dull green, loosely arranged spikelets, the lowest ones strongly reflexed, mark this species fairly easily. The other Missouri species with strongly reflexed spikelets (*C. lancastrisensis*, *C. Plukenetii*, *C. dipsaciformis*), all have more numerous spikelets in denser clusters. Of the species having reflexed spikelets, this one is quite characteristic of dry open wooded valleys and sandy or gravelly bars bordering Ozark streams.

19. *Cyperus lancastrisensis* Porter Map 381
Cyperus refractus var. *lancastrisensis* (Porter) Kük.
[Kükenthal]
Flowers August–October.

Occurs on rocky open slopes, glades, rocky open woods along streams, swales in prairies, and along railroad cuts through sandstone areas. Known only from Jasper, Newton, and Lawrence counties of southwestern Missouri, and St. Louis, Madison, and Wayne counties in the eastern Ozark section.

Ranges from Georgia to Arkansas and Missouri, north to New Jersey, Pennsylvania, and Ohio.

The short cylindric head of densely clustered spikelets with the lowest ones reflexed usually distinguish this species readily from *C. strigosus*. The spikelets are usually narrower than those of *C. strigosus* and much narrower than those of *C. filiculmis*. Occasional specimens are found (*Palmer* 66624 from Newton County) which are somewhat suggestive of hybridity between *C. lancastrisensis* and *C. filiculmis*, *C. ovalaris*, or *C. strigosus*. Such a specimen has shorter more subglobose inflorescences with somewhat broader (1.5–2 mm.) spikelets, which are 8–12 mm. long and 6–8-flowered. As compared with *C. filiculmis*, *C. strigosus*, and *C. ovalaris*, *Cyperus lancastrisensis* has a greater number of spikelets to a head than either *C. filiculmis* and *C. strigosus*, and fewer than in *C. ovalaris*. The spikelets of *C. lancastrisensis* average longer with more flowers than in *C. ovalaris*, but shorter than in *C. filiculmis*.

20. *Cyperus dipsaciformis* Fern. Map 382
Cyperus retrofractus var. *dipsaciformis* (Fern.) Kük.
[BB, Kükenthal]
Flowers July–October.

Occurs in sandy fields and sandy open woods, chiefly on Crowley Ridge of southeastern Missouri, where known only from Mississippi, Stoddard, and Dunklin (sands, Malden, September 8, 1910, *Bush* 6269B) counties.

Ranges from Georgia to southeastern Missouri, north to New Jersey, Maryland, D.C., and Kentucky.

21. **Cyperus Plukenetii** Fern. Map 383
Cyperus retrofractus var. *retrofractus* [of BB], not (L.)
 Torr. as treated by Fernald
Cyperus retrofractus [of P & S, Kükenenthal], not (L.)
 Torr.

Flowers July–September.

Occurs in sandy or open oak-hickory woodland in acid soils, where known only from southeastern Missouri in Stoddard, Dunklin (Bernie, August 2, 1895, *Bush* 688; Malden, August 27, 1894, *Bush* 6269), Ripley (Pleasant Grove, August 9, 1899, *Bush* 254), and Wayne counties.

Ranges from Florida to Texas, north to New Jersey, Ohio, and southeastern Missouri.

This species and *C. dipsaciformis* stand out among Missouri species in having obovoid or obconic dense inflorescences narrowed in the lower half with most of the spikelets reflexed, and are not likely to be confused with any other species. However, some difficulty may be encountered in telling the two species apart. The differences brought out in the key to species should clarify the main points of departure.

22. **Cyperus Schweinitzii** Torr. Map 384
 Flowers late June–September.

Occurs in dry sandy prairies or low sandy ground along streams and about ponds, and along railroads. Rare and scattered in central, western, and north-eastern Missouri, where locally north in Clark County (natural sandy prairie on old river terrace paralleling Des Moines River, T65N, R6W, sect. 9, 1½ mi. southeast of St. Francisville, August 18, 1949, *Steyermark* 68859); absent from the Ozark section.

Ranges from Quebec to Saskatchewan, south to New York, Pennsylvania, Ohio, Indiana, Illinois, Missouri, Oklahoma, Texas, and New Mexico.

Cyperus Schweinitzii may be distinguished in general from *C. filiculmis* var. *filiculmis* and var. *macilentus* by (1) the erect or ascending, instead of widely spreading or recurved, involucre bracts, (2) the usually scabrous-rough instead of smooth culm, (3) the culms usually more than 1 mm. in diameter below the inflorescence, instead of 0.5–1 mm., (4) the acuminate, awned, somewhat longer scales, (5) achenes 2.5–3.5 mm. long instead of 1.5–2.3 mm. long, (6) the slightly broader leaves which are mainly 2–6 mm. wide instead of mostly less than 2 mm. wide as in *C. filiculmis*, (7) the prevalence of elongated, well developed rays on some

or most of the spikelets, and (8) the pinnately arranged ascending spikelets instead of digitately arranged, spreading spikelets.

It apparently hybridizes with *C. filiculmis* var. *filiculmis* in St. Louis County and in western Missouri (where see discussion under *C. × mesochorus*). The main differences are indicated in the key to species.

- 22a. **Cyperus × mesochorus** Geise Map 384
Cyperus Houghtonii var. *uberior* Kükenenthal

Cyperus Bushii Britton, as to numerous specimens so identified by him, but not the type (*Bush* 619 from Arkansas, which is *C. filiculmis*).

Sister M. Joseph Geise (Am. Midl. Nat. 15: 249–50. 1934) considered this a hybrid between *C. Schweinitzii* and *C. Houghtonii*, whereas Father O'Neill (Rh. 44: 58. 1942) considers it as a form of *C. Schweinitzii* with more densely-clustered heads containing more numerous digitately- instead of more pinnately-arranged spikelets. He indicates (p. 57) that Britton's annotation of a number of specimens in the New York Botanical Garden Herbarium identified as *C. Bushii* Britton are identical with some of the specimens that would be classified as *Cyperus × mesochorus*. Gleason in the *New Ill. Fl.* (vol. 1. p. 252. 1952) interprets these intermediate types as possible hybrids between *C. filiculmis* and *C. Schweinitzii*, which is the viewpoint also taken by Father O'Neill (Rh. 44: 58. 1942).

Some of the specimens of *C. filiculmis* and *C. Schweinitzii* in the western sections of Missouri may show this intermediate character between *C. Schweinitzii* and *C. filiculmis*, and are to be interpreted as belonging to *C. × mesochorus*.

A collection from St. Louis County which has the characters of this hybrid is *Muehlenbach* 1485 (right-of-way of the Wabash Railroad, on a free place opposite the Wabash Fruit Terminal, west of Collins Street, September 7, 1958). Another collection from St. Louis County which suggests this hybrid and is somewhat intermediate between *C. filiculmis* and *C. Schweinitzii* is *Muehlenbach* 103 (right-of-way of Wabash R. R., south of the gravel plant at the foot of Branch Street, St. Louis, June 5, 1954).

23. **Cyperus filiculmis** Vahl Map 385
 Flowers last of May–October.

Occurs in dry open sandy or rocky woods, dry open ridges, prairies, glades of sandstone, chert, or granite, dry fallow and upland fields, and along railroads, generally in acid soils.

1

2

3

4

5

385 • *Cyperus filiculmis* var. *filiculmis*
385 □ *Cyperus filiculmis* var. *macilentus*

386 *Cyperus globulosus*

387 • *Cyperus ovalaris* var. *ovalaris* (Hedgehog Club Rush)
387 □ *Cyperus ovalaris* var. *sphaericus*

Missouri material may be divided into the following varieties:

Scales of spikelets 2.8–3.5 mm. long; spikelets 7–20 mm. long, mainly 6–16-flowered, rather loosely arranged; achenes 1.8–2.3 mm. long.

23a. *C. filiculmis* var. *filiculmis*

Scales of spikelets 1.8–2.8 mm. long; spikelets 3–15 mm. long, mainly 2–8-flowered, in a compact usually dense head; achenes 1.5–1.8 mm. long.

23b. *C. filiculmis* var. *macilentus*

23a. ***Cyperus filiculmis* var. *filiculmis*** Map 385
Cyperus filiculmis Vahl [G, BB, P & S]
Cyperus Bushii Britton
Cyperus Houghtonii Torr. var. *Bushii* (Britton) Kük.
[Kükenthal]

Scattered in southern and central Missouri north to Marion, Shelby, Macon, and Jackson counties.

Ranges from Florida to Texas, north to Massachusetts, New York, Ohio, Michigan, Illinois, Iowa, and Nebraska.

23b. ***Cyperus filiculmis* var. *macilentus*** Fern.

Map 385

This is the more common variety encountered, and is found nearly throughout the state, although relatively more rare in northern Missouri.

Ranges from Maine and Quebec to Minnesota, south to Virginia, Ohio, Indiana, Illinois, and Missouri.

Cyperus filiculmis var. *filiculmis* and var. *macilentus* sometimes resembles specimens of *C. compressus*. It is not always possible to know whether the plants are annual or perennial, a character sometimes used in keys to distinguish these species. In the absence of this knowledge, the species can be readily separated

on the basis of the achenes, which are only 1.2–1.5 mm. long in *C. compressus*, 1.5–2.3 in the varieties of *C. filiculmis*, scales more separated at maturity in *C. filiculmis* than in *C. compressus*, and more abruptly tipped in *C. filiculmis* instead of having gradually prolonged sharp tips as in *C. compressus*.

The two varieties of *C. filiculmis* inhabit usually quite dry habitats in poor acid soils or on rocks. There is definite intergradation between them, making it difficult to place them in one or the other category. Specimens with few-flowered (3–6) spikelets of *C. filiculmis* var. *macilentus* but with the longer scales and achenes of var. *filiculmis* are frequently found, and other noncorrelated combinations of characters occur, rendering a decision as to proper placement unsatisfactory. The two varieties are tentatively retained for Missouri, pending results of more intensive study.

24. ***Cyperus globulosus*** Aubl.

Map 386

Flowers July–October.

Occurs in open sandy or alluvial ground along the Mississippi and St. Francis rivers and in sandy open woods of Crowley Ridge, where found only in southeastern Missouri in Pemiscot and Dunklin (sands, Malden, September 8, 1910, *Bush* 6270; woods, Campbell, September 7, 1910, *Bush* 6222; Kennett, July 27, 1895, *Bush* 683) counties.

Ranges from Florida to Texas, north to Virginia, Missouri, and Oklahoma; also in Central and South America, the West Indies, and southern Mexico; locally introduced north to New Jersey and Pennsylvania.

25. ***Cyperus ovalaris*** (Michx.) Torr.

Hedgehog Club Rush

Map 387

Flowers first of June–September.

PLATE NO. 70

Occurs in dry open woods, prairies, glades of sandstone, chert, and granite, in sandy soils along streams, dry fallow or upland fields, and open banks along roadsides and railroads, generally in acid soils.

Two varieties may be distinguished in Missouri:

Inflorescence mostly longer than thick, 11–23 mm. long, 8–18 mm. thick. . . . 25a. *C. OVULARIS*

var. *OVULARIS*

Inflorescence mostly globe-shaped, about as long as thick, 7–12 (–15) mm. long, 7–12 (–15) mm. thick. . . . 25b. *C. OVULARIS* var. *SPHAERICUS*

25a. ***Cyperus ovularis* var. *ovularis*** Map 387

Cyperus ovularis (Michx.) Torr. [G, BB]

Cyperus ovularis var. *robustus* Boeckl. [P & S]

Cyperus ovularis var. *Wolfii* (Wood) Kük. [Kükenthal]

Common in southern and central Missouri north to Lincoln, Boone, and Jackson counties.

Ranges from Florida to Texas, north to New York, New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Missouri, and Kansas.

25b. ***Cyperus ovularis* var. *sphaericus*** Boeckl.

Map 387

Scattered in the range of var. *ovularis*, in southern and central Missouri, but less common. Representative specimens are from Jackson (*Bush 41*), Johnson (*Palmer 66529*), and Polk (*Palmer 66968*) counties.

Ranges from Georgia to Texas, north to Virginia, West Virginia, Ohio, Indiana, Missouri, and Oklahoma.

26. ***Cyperus tenuifolius*** (Steud.) Dandy

Map 388

Kyllinga pumila Michx. [P & S]

Cyperus densicaespitosus Mattf. & Kükenth. [BB]

Flowers late May–October.

Occurs on gravel bars and muddy banks of streams, moist margins of ponds, wet places in prairies, and wet open woods. Southern and central Missouri north to Clay, Boone, and Marion counties.

Ranges from Mexico, Central and South America, and in North America from Florida and Texas, north to New York, Pennsylvania, Ohio, Indiana, Illinois, Missouri, and Kansas.

Excluded species

13. ***Cyperus Engelmannii*** Steud.

Cyperus ferax subsp. *Engelmannii* (Steud.) Kük. [Kükenthal]

The basis for crediting this species to St. Louis,

Missouri rests upon specimens collected by *Engelmann* with the data: 'muddy banks of the Cahokia near St. Louis, October, 1845,' and 'on Cahokia Creek near St. Louis, September, 1846.' Unfortunately, *Engelmann* did not take the trouble to indicate on the labels accompanying these specimens that they were collected in Illinois. All the other specimens of *C. Engelmannii* collected by *Engelmann* at the same time and place bear data which are more specific, as follows: 'on Cahokia Creek, St. Clair County, Illinois,' 'on Cahokia Creek in the bottom opposite St. Louis, September, 1846,' and 'shady muddy banks of Cahokia Creek opposite St. Louis, October, 1845.'

The dates of October, 1845 and September, 1846 and Cahokia Creek accompany the labels of both the specimens placed in Illinois and those interpreted for Missouri. There is no doubt whatsoever that the data apply to the same locality on Cahokia Creek in St. Clair, Illinois, opposite St. Louis.

With more intensive collecting in the future in the area along the Mississippi River bottoms on the Missouri side, it is expected that *C. Engelmannii* will eventually be found in the state.

Cyperus filicinus Vahl

Kükenthal (*Das Pflanzenreich* IV: 20. Heft. 101. p. 374. 1956) records this species from St. Louis County, citing *C. polystachyos* var. *macrostachyus* Boeckl., in synonymy.

As stated by *Fernald* (Rh. 41: 531, 1939) and by *Father O'Neill* (Rh. 44: 84. 1942) *C. filicinus* is a maritime species confined to salt or brackish-water habitats along the Atlantic Coast from Maine to Florida west along the Gulf Coast to Louisiana. As *Fernald* (*ibid.*) points out, dwarfed plants of *C. polystachyos* var. *texensis* resemble dwarfed extremes of *C. filicinus*, and it is possible that the St. Louis County specimen cited by Kükenthal is based upon such a mistaken resemblance. However, since *C. polystachyos* var. *texensis* is known only from the counties of extreme southeastern Missouri, it is probable that another more common species has been confused with *C. filicinus*.

Cyperus retrofractus (L.) Torr.

Cyperus retrofractus var. *retrofractus* [BB]

Kükenthal (*Das Pflanzenreich* IV: 20. Heft 101. pp. 507, 509. 1956) cites *Bush 688* in crediting this species to Missouri. As interpreted in the present flora, however, *Bush 688* from Dunklin County is *C. Plukenetii* Fern., which, following *Fernald's* treatment, is distinguishable as a different species from *C. retrofractus* (L.) Torr. *Cyperus retrofractus*, following *Fernald's* interpretation (Rh. 47: 111–12. pl. 878, fig.

1-4) of that taxon, is a species with glabrous culms and leaves, glabrous rays of the inflorescence, golden brown or drab scales of the spikelets, and achenes 2-2.5 mm. long. The distribution of this species lies to the east of Missouri, and thus far, no true *C. retrofractus* has been collected in the state.

Cyperus retrorsus Chapm., var. **Deeringianus** (Britton & Small) Fern. & Griscom
Cyperus cylindrostachys Small

Kükenthal (Das Pflanzenreich IV: 20. Heft 101 1956) based his Missouri report on a specimen collected by Tracy from Ocean Springs. Unfortunately, Ocean Springs is in Mississippi, and all of Tracy's other Ocean Springs collections are known to come from Mississippi, not Missouri. The range of *C. retrorsus* var. *Deeringianus* is in the Coastal states from Mississippi and Florida to Georgia and Virginia.

2. **Dulichium** Pers.

Perennials with terete (rounded) culms leafy to the summit, the leaves short and 3-ranked. Spikelets linear, stalkless, in 2 ranks from the leaf-sheaths. Each flower consists of 6-9 downwardly barbed bristles, 3 stamens, and 2-cleft style. Achene beaked with a persistent style.

Dulichium arundinaceum (L.) Britt.
Three-way Sedge
Flowers July-October.

Map 389

Occurs in the mucky soil and floating mats of sink-hole ponds in the Ozarks, elsewhere in low ground bordering sloughs, ponds, and spring branches. Southern and central Missouri, north to St. Charles, Boone, and Jackson counties. Absent from the south-

eastern Missouri lowland section. Most abundant in sink-hole ponds of the Ozarks, and locally in southwest Missouri in Newton County (wet rocky ground along bed of spring brook, Haddock Spring, 3 mi. northwest of Wentworth, October 29, 1953, *Palmer 57135*; low wet ground along margin of slough Sagmount, 3 mi. south of Saginaw, July 31, 1953, *Palmer 56325*).

3. *Eleocharis* R. Br. Spike Rush

Glabrous annuals or perennials, the culms (stems) with leaf-sheaths at their base. Leaf-blades absent. Flower of usually 6 (3–12) bristles or the bristles not present, 3–1 stamens, and a 2–3-cleft style. Base of style persistent in fruit on summit of achene as a tubercle, either enlarged and conspicuous or not enlarged. Achene 2-sided (lenticular) or 3-sided (trigonus).

- a. Culms (stems) 4-angled and mainly 2–5 mm. thick 2. *E. QUADRANGULATA* var. *CRASSIOR*
- a. Culms flattened, rounded, or angled, but if 4-angled, then only 0.5–1 mm. thick b
- b. Culms marked cross-wise (transversely) by lines (septations) or partitions 1–5 cm. apart
- 1. *E. EQUISETOIDES*
- b. No cross (transverse) lines present on culms c
- c. Plants usually of limestone glades or prairies, or more rarely openings in upland woods; thickened creeping underground rhizome present, 2–5 mm. thick; culms strongly flattened, conspicuously 2-sided, 1–2 mm. wide; scales of spikelets with long-pointed whitish tips which are often cut into 2 at summit; styles 3-cleft; achenes finely roughened or wrinkled.
- 12. *E. COMPRESSA*
- c. Without such a combination of characters d
- d. No bristles present at base of any flower or achene e
- e. Styles 2-cleft; achenes 2-sided or with 2 angles f
- f. At least the scales half-way up the spikelet obtuse or rounded at the summit; 1 sterile scale at the base of spikelet completely encircling the base of spikelet; culms half-way up 0.5–1.5 mm. (rarely up to 2 or more) thick (in dried condition) 11. *E. CALVA*
- f. At least the scales half-way up the spikelet with an acute or acuminate point, rarely obtuse; 2 or 3 sterile scales at very base of spikelet and not encircling the base of spikelet; culms 0.5–5 mm. thick (in dried condition) g
- g. Culms usually soft or flattened; spikelets usually long-tapering to acuminate, 10–30 mm. long; fertile scales rather closely pressed against one other (appressed).
- 10. *E. MACROSTACHYA*
- g. Culms usually firm, wiry, and terete (cylindrical or in cross-section rounded); spikelets either pointed (acute) or obtuse (blunt) at summit, 5–20 mm. long; fertile scales more loosely ascending 9. *E. SMALLII*
- c. Styles 3-cleft; achenes 3-sided or with 3 or more angles h
- h. Plants restricted to salt-impregnated (saline) or alkaline soils or brackish water around salt or sulfur springs, or around old coal strip mines; achenes smooth, without slender longitudinal ribs; top of achene gradually narrowed into the crowning tubercle (persistent base of style) without any constricted area noticeable; culms terete (rounded in cross-section), but marked with fine vertical lines (striae) in dried state 3b. *E. PARVULA* var. *ANACHAETA*
- h. Plants of fresh-water ponds, springs, or sloughs or wet prairies; achenes with slender longitudinal ribs and cross (transverse) ridges or honey-combed (reticulate); top of achene separated from the crowning tubercle by a definite constriction; culms flattened and 2-sided or angled and furrowed i
- i. Plants with firm, strong, tough, dark rhizomes 1–3 mm. thick; achenes honey-combed (reticulate); scales reddish-, purplish-, or dark chestnut brown with white margins 13. *E. TENUIS* var. *VERRUCOSA*
- i. Plants with a slender rhizome or with hair-like tuber-bearing stolons or rhizomes; achenes with longitudinal ribs and transverse ridges; scales either pale green, greenish-white, or buff tinged with pale brown or purplish or purple-lined. j
- j. Common plant in or bordering fresh-water ponds, springs, or sloughs, and throughout Missouri; culms (stems) less than 0.5 mm. thick, angled (more than 2 angles) and furrowed; spikelets flattened, 0.7–1.5 mm. wide, 3–15-flowered; middle scales of spikelets 1.5–2.5 mm. long; roots bearing hair-like tuberous stolons 4. *E. ACICULARIS*
- j. Rare plant of wet prairies, and known only from Linn Co.; culms (stems) about 1 mm. (0.6–1.3) thick, flattened and 2-sided; spikelets terete (cylindrical), 2–3 mm. wide, mainly 16–20-flowered; middle scales of spikelets about 3 mm. long; slender creeping rhizomes present 5. *E. WOLFII*
- d. Bristles present at base of each flower or achene k

- k. Plants restricted to salt-impregnated (saline) or alkaline soils or brackish water around salt or sulfur springs, or around old coal strip mines; top of achene gradually narrowed into the crowning tubercle (persistent base of style) with no constricted or separated portion evident. . . . 3a. *E. PARVULA*
var. *PARVULA*
- k. Plants of many other kinds of habitats; top of achene separated from the crowning tubercle (persistent base of style) by either a definite constriction or line of separation l
- l. Styles 2-cleft; achenes 2-sided or with 2 angles m
- m. Annuals with fibrous or fleshy roots and no creeping rhizomes (care must be taken to collect complete specimens with roots and basal parts); top of achene separated from the crowning tubercle by a division line but the tubercle not constricted at its base from the top of the achene . . . n
- n. Scales of spikelet definitely acute (pointed) at tip; spikelets more or less lanceolate and long-tapering or acuminate at summit 8. *E. LANCEOLATA*
- n. Scales of spikelet usually rounded or obtuse (blunt) at summit; spikelets cylindrical to broadly ovoid, rounded or obtuse or slightly pointed (subacute) at summit. o
- o. Bristles either scarcely reaching to the beginning of the crowning tubercle on the achene or very much shorter; tubercle less than $\frac{1}{4}$ as long as the achene and noticeably depressed-triangular 6. *E. ENGELMANNI*
- o. Bristles usually longer than the combined length of achene and tubercle; tubercle $\frac{1}{3}$ – $\frac{1}{2}$ the length of achene, broadly triangular 7. *E. OBTUSA*
- m. Perennials with creeping or horizontal rhizomes (care must be taken to collect complete specimens with roots and basal parts); top of achene separated from the crowning tubercle (persistent base of style) by a definite constriction. p
- p. At least the scales half-way up the spikelet obtuse or rounded; 1 sterile scale at base of spikelet completely encircling the base of spikelet; culms 0.5–1.5 mm. thick (in dried condition) 11. *E. CALVA*
- p. At least the scales half-way up the spikelet with an acute or acuminate point, rarely obtuse; 2 or 3 sterile scales at very base of spikelet and not encircling the base of spikelet; culms 0.5–5 mm. thick (in dried condition) q
- q. Culms usually soft or flattened; spikelets usually long-tapering to acuminate, 10–30 mm. long; fertile scales rather closely pressed against one another (appressed). 10. *E. MACROSTACHYA*
- q. Culms usually firm, wiry, and terete (cylindrical or in cross-section rounded); spikelets either pointed (acute) or obtuse (blunt) at summit, 5–20 mm. long; fertile scales more loosely ascending 9. *E. SMALLII*
- l. Styles 3-cleft; achenes with 3 or more angles, not noticeably angled, or only 2-angled r
- r. Culms hair-like or thread-like, mainly 0.1–1 mm. thick, finely angled with ridges and furrows; spikelets chiefly 0.7–2 (up to 2.8) mm. wide; achenes with the surface honey-combed (reticulate) or minutely roughened or wrinkled; perennials creeping and forming mats with either an obvious thickened cord-like rhizome 1–3 mm. thick or a thread-like tuber-bearing minute rhizome s
- s. Culms hair-like, usually 0.1–0.4 mm. thick; spikelets mainly 0.7–1.5 mm. wide; scales mainly pale green to greenish-white, only slightly tinged sometimes with brownish or purplish; achenes minutely roughened or wrinkled; rhizome hair-like, delicate, tuber-bearing 4. *E. ACICULARIS*
- s. Culms of the thickness of coarse thread, 0.3–1 mm. thick; spikelets mainly 1.5–2.5 mm. wide; scales mostly reddish- to purple- or chestnut-brown with broad white or pale margins and tips; achenes with a honey-combed (reticulate) surface; rhizome obvious, thickened, cord-like, 1–3 mm. thick 13. *E. TENUI* var. *VERRUCOSA*
- r. Culms 0.3–1.5 mm. thick, terete (rounded in cross-section) and rather smooth, without deep furrows; spikelets chiefly 2–5 mm. wide; achenes smooth and shining; annuals with fibrous or fleshy roots t
- t. Scales of spikelet definitely acute (pointed) at tip; spikelets more or less lanceolate and long-tapering or acuminate at summit 8. *E. LANCEOLATA*
- t. Scales of spikelets usually rounded or obtuse (blunt) at summit; spikelets cylindrical to broadly ovoid, rounded or obtuse or slightly pointed (subacute) at summit. u
- u. Bristles either scarcely reaching to the beginning of the crowning tubercle on the achene or very much shorter; tubercle less than $\frac{1}{4}$ as long as the achene and noticeably depressed-triangular 6. *E. ENGELMANNI*
- u. Bristles usually longer than the combined length of achene and tubercle; tubercle $\frac{1}{3}$ – $\frac{1}{2}$ the length of the achene, broadly triangular 7. *E. OBTUSA*

1. ***Eleocharis equisetoides*** (Ell.) Torr. Map 390
Flowers July–October.

Known only from a sink-hole pond in Oregon County, southern Missouri (Tupelo Gum Pond, Clark National Forest, T25N, R4W, sect. 4, 9 mi. west of New Liberty, July 24, 1936, *Steiermark 12266*).

Ranges from Florida to Texas, north to North Carolina, Maryland to Massachusetts, New York to Wisconsin, Illinois, and Missouri.

One of the isolated relicts in the sink-hole ponds of the Ozarks.

2. ***Eleocharis quadrangulata*** (Michx.) R. & S. var. ***crassior*** Fern. Map 391

Eleocharis quadrangulata [of P & S]

Flowers from first part of June–October.

Occurs along muddy margins of ponds and streams in the Ozark section of southern and east-central Missouri northeast to St. Louis County, west to Pulaski, Laclede, Greene, and Newton counties.

Ranges from Florida to Texas, north to Massachusetts, New York, Ontario, Ohio, Michigan, Wisconsin, Missouri, and Oklahoma.

3. ***Eleocharis parvula*** (R. & S.) Link Map 392
Flowers July–October.

Occurs in marshy ground bordering saline springs and ponds in Ralls, Cooper, and Saline counties, and along alkaline muddy or sandy margins of old coal strip mines in southwest Missouri in Jasper (near Duenweg, June 15, 1952, *Palmer 54312*) and Barton (1 mi. southeast of Burgess, August 27, 1952, *Palmer 54972*; 1½ mi. southeast of Minden Mines, August 19, 1954, *Palmer 58601*) counties:

3a. ***Eleocharis parvula* var. *parvula*** Map 392

The typical variety with bristles is the commoner variety encountered in the state.

Ranges from Newfoundland to Louisiana, inland locally to New York, Michigan, Missouri, and Minnesota; also in British Columbia to California, the West Indies, South America, Europe, and Africa.

3b. ***Eleocharis parvula* var. *anachaeta*** (Torr.)

Svenson

Map 392

This variety which lacks bristles is more rarely encountered in the state.

Ranges from Minnesota and Iowa to Oregon, south to Louisiana, Texas, and Mexico; also in the West Indies and South America.

A rare species restricted to alkaline or saline spots in the state. Around Elk Lick Springs in Saline County, Chouteau Springs in Cooper County, and at a saline lake in the valley of Salt Lick Creek, Ralls County (*Steiermark 66458*), it occurs as a native species, associated frequently with *Zannichellia palustris*, *Scirpus paludosus*, *Typha angustifolia*, and *Diplachne acuminata*, and from a salt lick east of Elk Lick Springs with the isolated inland relict, *Distichlis spicata*. It has been introduced around the old coal strip mines in southwestern Missouri.

4. ***Eleocharis acicularis*** (L.) R. & S. Map 393
Flowers July–October.

Occurs commonly along margins of natural and artificial ponds, sloughs, and in springs. Often occurring as dense mats in dried-up temporary ponds.

Missouri material may be segregated as follows:

a. Culms sterile (without spikelets at tip)

4b. *E. ACICULARIS* var. *ACICULARIS* f. *LONGICAULIS*

a. Culms fertile (with spikelets at tip) b

PLATE NO. 71

396 □ *Eleocharis obtusa* var. *jejuna*

- b. Culms 0.2–20 cm. long; spikelets mainly 2–6 mm. long, mainly 3–8-flowered, ovate to lanceolate 4a. *E. ACICULARIS* var. *ACICULARIS* f. *ACICULARIS*

- b. Culms mainly 30–40 cm. long; spikelets mainly 5–12 mm. long, chiefly 9–20-flowered 4c. *E. ACICULARIS* var. *ACICULARIS* f. *FLUITANS*

4a. ***Eleocharis acicularis* var. *acicularis* f. *acicularis***

Map 393

Eleocharis acicularis (L.) R. & S. [G, BB, P & S]

This is the common variety encountered in the state, where it occurs throughout the Ozark section and scattered elsewhere northward; absent from large sectors of northern and central Missouri.

Ranges from Labrador to British Columbia, south to Florida, Tennessee, Missouri, Oklahoma, New Mexico, and California; also in Eurasia.

4b. ***Eleocharis acicularis* var. *acicularis* f. *longicaulis***

(Desmaz.) Hegi

Map 393

Scattered throughout the range of the typical variety in the state.

4c. ***Eleocharis acicularis* var. *acicularis* f. *fluitans***

(Doell.) Svenson

Map 393

Eleocharis acicularis var. *gracilescens* Svenson [P & S]

Scattered in portions of southern and east-central Missouri, principally in springs and stagnant pools.

Known from Tennessee to Oklahoma and California; also in Europe.

Svenson (Rh. 31: 183–91. 1929) has attempted to subdivide *E. acicularis* into numerous varieties and forms on the basis of assumed ecological and morphological differences. In greater depths of water, it is possible to find plants with the culms more greatly elongated than ordinarily, and these can be classified as *f. longicaulis*, if sterile, or *f. fluitans*, if fertile. Plants occurring in temporary ponds or ponds subject to

drying conditions or to changing shore lines often have culms shorter than usual and appear stunted; such plants are common *E. acicularis* var. *acicularis* f. *acicularis*.

Study of material separated by Svenson as var. *gracilescens*, characterized by the elongated culms and linear spikelets, would indicate that this variation cannot be kept separate from *f. fluitans*. The spikelets of these plants, most of the culms of which grow in a greater depth of water, are usually more elongated and have more flowers per spikelet than in the common variety *acicularis* with shorter culms and smaller spikelets. In the specimen of Palmer 66173 from Newton County, the culms are 40 cm. long, up to 0.5 mm. thick, the spikelets are linear or lanceolate-linear up to 12 mm. long and with flowers from 9–20. The flowers in Palmer's specimen also possess bristles. Actually, although Svenson described var. *gracilescens* as having no bristles, Missouri material is found either with or without bristles. Svenson (N. Am. Fl. 18, part 9: 516. 1957) describes the color of the bristles in *E. acicularis* as 'brownish,' but in fresh or recently dried material the bristles are white or whitish.

As the variations of this species become subjected to more detailed experimental investigations, a more positive statement may be forthcoming as to the relative worth of the various forms that have been described. At present, it would appear that some correlation exists between the relative length of culm and spikelet and the relative depth of water, but that no more than a normal ecological range of variation exists in the environment of this species; and it is, therefore, questionable whether names should be given for such normal variations.

5. ***Eleocharis Wolfii* Gray**

Map 394

Flowers May–July.

Known only from Linn County, northern Missouri (uncommon around swale in bottom prairie along

East Yellow Creek, 6 mi. east of Brookfield, June 5, 1936, *Steyermark 11028*).

Ranges from Indiana to Iowa and Colorado, south to Tennessee, Louisiana, and Oklahoma; also in New York and Saskatchewan.

6. ***Eleocharis Engelmanni*** Steud. Map 395

Eleocharis Engelmanni var. *robusta* Fern. [P & S]

Flowers May–October.

The type locality is St. Louis, Missouri, collected by *Engelmann* in 1845.

Occurs along muddy margins of ponds, sloughs, and, occasionally, streams, rarely along roadside ditches. Scattered in parts of southern and central Missouri north to Lincoln and Jackson counties. A collection from Boone County labeled *E. Engelmanni* (near More's Lake, Columbia, July, 1908, *Daniels*) proves upon examination to be *E. obtusa*.

Ranges from Maine to Saskatchewan and Washington, south to Virginia, Georgia, Arkansas, Texas, Arizona, and California.

A form in which the bristles are absent, f. *detonsa* (Gray) *Svenson*, has not been found in Missouri, but is known from localities near the state's boundaries, and is eventually expected to occur.

7. ***Eleocharis obtusa*** (Willd.) Schultes Map 396

Flowers May–October.

Occurs along muddy borders of ponds, sloughs, and streams, temporary pools and roadside ditches. The commonest spike-rush in Missouri, where known from all but the northwestern section of the state.

Missouri material may be classified into the following varieties:

Spikelets 2–16 mm. long, many-flowered (40–150 or more); scales of spikelets pale or yellow-brown with white margins, erect and close against one another; achenes 1–1.5 mm. long, the tubercle $1/3$ – $1/2$ the length of the achene . . . 7a. *E. obtusa*

var. *obtusa*

Spikelets 2–5 mm. long, few-flowered (mainly 6–12, but up to 20); scales of spikelets usually purplish or brown-purple with paler margins, spreading; achenes 0.9–1.3 mm. long, the tubercle nearly $1/2$ the length or slightly shorter than $1/2$ the length of the achene . . . 7b. *E. obtusa*

var. *jejuna*

7a. ***Eleocharis obtusa*** (Willd.) Schultes var.

obtusa

Map 396

The common variation in Missouri.

Ranges from Nova Scotia to Minnesota, south to Florida, Alabama, Mississippi, Florida, and Texas; also British Columbia to California, and Hawaii.

7b. ***Eleocharis obtusa*** var. ***jejuna*** Fern. Map 396

Known only from two scattered localities, in Sullivan (sandy and muddy shallow bars of East Fork of Medicine Creek, T62N, R22W, sect. 2, $1/4$ mi. east of Osgood, September 21, 1955, *Steyermark 79815*) and Lawrence (muddy margins of artificial spring-fed pond, state fish hatchery, Chesapeake, October 17, 1956, *Palmer 64613*) counties.

Known from Nova Scotia and New England to Virginia, and locally in Missouri.

The above-cited collections are the only ones that can be considered to come within the limits of the var. *jejuna*. This variety has slender culms about 0.5 mm. thick and only 1–10 (rarely to 20) cm. tall. Dwarfed specimens of *E. obtusa* var. *obtusa* with culms very slender are sometimes mistaken at first for var. *jejuna*, but have larger heads with more numerous flowers and pale brown scales.

Eleocharis obtusa varies considerably in height and thickness of culm, and length, thickness, and shape of spikelet. *Svenson* (Rh. 31: 216. 1929) considers var. *jejuna* an ecological state of the species growing in muddy places subjected to flooding. He further expresses his belief that this species might be considered as part of a variable series combined with *E. Engelmanni*, *E. lanceolata*, *E. diandra*, and *E. ovata* (N. Am. Fl. 18, part 9: 519. 1957). Until future studies, perhaps along experimental lines, have been conducted with these species, the present treatment is in accord with general botanical opinion.

8. ***Eleocharis lanceolata*** Fernald Map 397

Flowers June–October.

Occurs in wet sandy open ground, muddy margins of small ponds, and in moist depressions on glades. Known only from southern Missouri in Carter, Jasper, and Barton counties.

Ranges from southern Missouri to Arkansas, Oklahoma, and Texas.

The character of the length of the tubercle, ascribed by authors to this species, as a distinguishing criterion, has been found to break down in the case of some collections. In the collection of *Palmer 65905* from Newton County, the tubercle is mostly only $1/3$ instead of $1/2$ the height of the achene, thereby breaking down one of the differences often used to separate *E. lanceolata* from *E. obtusa*, as noted in *Svenson's* treatment in *North America Flora* (p. 518–20).

9. ***Eleocharis Smallii*** Britt. Map 398

Eleocharis palustris [of BB] in part, not (L.) R. & S. Flowers from the first of June–September.

Occurs along borders of swamps, sloughs, ponds,

397 *Eleocharis lanceolata*398 *Eleocharis Smallii*399 *Eleocharis macrostachya*

streams, roadside ditches, and in wet meadows and prairies. Scattered throughout the state.

Ranges from Newfoundland to Ontario, south to Maryland, Pennsylvania, West Virginia, Indiana, Illinois, and Missouri.

10. ***Eleocharis macrostachya* Britt.** Map 399
Eleocharis palustris [of BB] in part, not (L.) R. & S.
Eleocharis mamillata [of P & S], not Lindb. f.
 Flowers late May–August.

Occurs along muddy margins of ponds, sloughs, swamps, streams, and in prairie swales. Rather rare and scattered in Missouri, mostly absent in the Ozark section.

Ranges from Minnesota to Saskatchewan and British Columbia, south to Illinois, Louisiana, Texas, Mexico, and California.

11. ***Eleocharis calva* Torr.** Map 400
Eleocharis erythropoda Steud. [Svenson]
 Flowers from first of June–September.

Occurs along margins of ponds, sloughs, streams, and in wet prairies and meadows.

Throughout Missouri, except apparently absent from the extreme southeastern lowland section and parts of western Missouri.

Ranges from Gaspé Peninsula, Quebec, to Manitoba, south to Virginia, Tennessee, Arkansas, Oklahoma, and New Mexico; also in Hawaii and Asia.

Of the group having prominent creeping rhizomes and growing near the water (*E. Smallii*, *E. macrostachya*, and *E. calva*), this is the most frequently encountered, and the commonest throughout the Ozark section, where it borders most of the small and large streams. It also possesses the most slender culms of the group. As with the other members of the group, bristles may be present or absent.

12. ***Eleocharis compressa* Sulliv.** Map 401
 Flowers early May–July.

Occurs most frequently on limestone glades and wet depressions throughout the Ozark section of southern and central Missouri, infrequently and locally northwest in prairies, along roadside ditches, and openings in upland woods northwest to Nodaway and Atchison counties.

Ranges from Quebec and New York to Saskatchewan, south to Virginia, Georgia, Alabama, Missouri, Texas, and Colorado.

This species is a characteristic one on calcareous exposures, limestone glades, and 'bald knobs' throughout the Ozark region, where it is frequently associated with such other plants as *Leavenworthia uniflora*, *Arenaria patula* f. *Pitcheri*, *Galium virgatum*, and *Ophioglossum Engelmanni*.

It is easily identified usually by the combination of flattened, relatively broad culms, thick creeping rhizomes, and long-pointed, white-tipped scales which are often split in two at the summit; such plants are characteristic of the Ozark area. There are specimens found, however, in western Missouri north of the Missouri River which are not quite typical in certain respects, and may be mistaken for *E. tenuis* var. *verrucosa*. Such plants may have rather more slender culms, which, because of their striations, may even appear angled as in *E. tenuis*, and are somewhat intermediate in appearance between the two species; they may be of hybrid origin.

Svenson likewise indicates (Rh. 34: 217–18. 1932) that difficulty may be experienced in distinguishing *E. compressa* from *E. tenuis* (known at that time as *E. capitata*) at the borders of range of the two species and notes also the narrower culms of *E. compressa* which may be evident in such marginal areas where the ranges of these two species overlap.

5
PLATE NO. 72

400 *Eleocharis calva*401 *Eleocharis compressa*402 *Eleocharis tenuis* var. *verrucosa*13. *Eleocharis tenuis* (Willd.) Schultes var.**verrucosa** Svenson

Map 402

Eleocharis capitata (L.) R. Br. var. *verrucosa* Svenson
[P & S]

Flowers early May–September.

Occurs in wet places in prairies, glades, prairie swales along railroad tracks, roadside openings, along ditches, wet places in woods, and wet ground bordering sloughs. Common throughout Missouri.

Ranges from Indiana and Iowa, south to Kentucky, Illinois, Louisiana, and Texas; also in Virginia.

In general, there is not too much difficulty in distinguishing this species from *E. compressa*, especially in mature fruiting stage, at which time the reticulate achenes of *E. tenuis* var. *verrucosa* easily separate it from the granular-roughened or wrinkled ones of *E. compressa*. However, in younger stages of flowering, difficulty is sometimes experienced, as the two species strongly resemble one another. The scales of *E. tenuis* var. *verrucosa* are often as acute and may have nearly as prominent white margins and summits as in *E. compressa*, the rhizomes are sometimes nearly as thick as in *E. compressa*, although usually more curving and more slender (1–3 mm. thick), and the culms of *E. tenuis* var. *verrucosa* may even appear flattened, after having been dried and pressed. For the most part, however, the culms of *E. tenuis* var. *verrucosa* are found to be more slender (0.3–1 mm. thick) than those of *E. compressa* (mostly 1–2 mm. thick), and, if cross-sectioned, usually show 4 angles with somewhat

depressed or concave sides or 5 angles and the 4 to 8 fibrovascular bundles separate; in *E. compressa* the culm is usually broad and flattened with a continuous fibrovascular system. In general, the scales of *E. tenuis* var. *verrucosa* have the greater portion of their area darker maroon and a corresponding smaller area of white margin and apex than in those of *E. compressa*, the scales also being more rounded to obtuse.

Certain collections from western Missouri north of the Missouri River greatly resemble *E. compressa* and seem to merge with that species. Perhaps these are of possible hybrid origin. Svenson notes (Rh. 34: 218. 1932) that the achene in *E. compressa* has a tendency to be more rounded than that of *E. tenuis* with less conspicuous surface markings and the tubercle usually in the form of a low cone.

Some authors have attempted to indicate a difference in the apex of the leaf-sheath, that of *E. tenuis* var. *verrucosa* being cut off at an angle (obliquely) and that of *E. compressa* being cut square across (truncate) at the top. These differences, in the case of much Missouri material examined, do not seem to hold, however, and therefore this character has not been used as a reliable one in distinguishing the two species. Due to the broader culms of *E. compressa*, however, with the summit of the leaf-sheath usually more truncate, there is a somewhat more conspicuous darker margin and color contrast to the culm than in *E. tenuis* var. *verrucosa*.

4. *Bulbostylis* (Kunth) C. B. Clarke

Annuals (in the local species) growing in dense tufts with hair-like leaves and culms, the leaf-sheaths finely short-hairy. Stamens 2 or 3. Style 2–3-cleft, the base enlarged and persisting as a tubercle.

Bulbostylis capillaris (L.) C. B. Clarke. Map 403*Stenophyllus capillaris* (L.) Britton [P & S]*Bulbostylis capillaris* var. *crebra* Fern. [G]*Bulbostylis capillaris* var. *isopoda* Fern. [G]

Flowers July–October.

Occurs in thin acid soils and on rocks of sandstone,

403 *Bulbostylis capillaris*

404 *Fimbristylis caroliniana*

405 *Fimbristylis dichotoma*

chert, and granite on glades and barrens, and swales in prairies. Southern, central, and eastern Missouri northeast to Lewis County.

Ranges from Maine and Quebec to Minnesota, south to Florida and Texas; also in the Pacific states, northern Mexico, Central America, and Cuba.

Fernald (Rh. 40: 394-95. 1948) has attempted to divide the species into three varieties separated as follows:

- a. Crowded sessile spikelets occurring at the base of the leaves . . . B. CAPILLARIS var. CAPILLARIS
- a. No sessile spikelets occurring at the base of the leaves b

- b. Lateral spikelets on unequal pedicels 0.1-1 cm. long . . . B. CAPILLARIS var. CREBRA
- b. Lateral spikelets on nearly equal pedicels 0.6-3 cm. long. . . B. CAPILLARIS var. ISOPODA

Plants which fit the above classification can be found in the state, but they do not appear to show any constancy in their occurrence, all types of variations being found in a noncorrelated manner and intergrading. It would seem that Missouri material at least cannot fit into Fernald's scheme of classification.

5. **Fimbristylis** Vahl

Annuals or perennials with slender narrow leaves. An involucre of 2-3 leaves at the base of the umbellate inflorescence. Flowers consist of 1-3 stamens, 2-3-cleft style, the base of style deciduous, and no bristles or scales.

- a. Some hairs present at least on the lowermost scales of a spikelet (often on all the scales of younger spikelets); perennials with a thickened or bulb-like base. 1. F. CAROLINIANA
- a. All the scales of a spikelet glabrous (without hairs); annuals with a soft non-thickened base b
- b. Scales of spikelets usually pale green or greenish-white; each spikelet stalkless (sessile), all close together in a compact cluster; spikelets appearing as if hidden in the greatly elongated hair-like leaves and involucre 3. F. VAHLII
- b. Scales of spikelets shades of brown; 1 or more of the spikelets on slender stalks; spikelets raised on elevated culms (stems) usually equalling or longer than the leaves c
- c. Spikelets ovoid (egg-shaped), chiefly 2.5-3 mm. wide, chiefly 2-2½ times as long as broad; leaves with fine hairs on margins; style 2-cleft; achene 2-sided (lenticular) with 6-8 conspicuous longitudinal ribs on each surface 2. F. DICHOTOMA
- c. Spikelets narrowly linear- or ovate-lanceolate or narrowly elliptic, 1-1.5 mm. wide, chiefly 3-4 times as long as broad; leaves glabrous; style 3-cleft; achene 3-sided (trigonus), smooth and shining or with a surface faintly and finely honeycombed (reticulate) 4. F. AUTUMNALIS

- 1. **Fimbristylis caroliniana** (Lam.) Fern.
Map 404
Fimbristylis castanea (Michx.) Vahl [P & S]
Fimbristylis castanea var. *puberula* (Michx.) Britton [P & S]
Fimbristylis Drummondii Boeckl. [G]
Fimbristylis interior Britton
Fimbristylis puberula (Michx.) Vahl

Flowers early May-July.
Occurs on open limestone, chert, or sandstone glades, upland sometimes sandy prairies, and rocky openings in woodland. Southern and central Missouri north to St. Louis, Montgomery, Moniteau, Pettis, and Jackson counties; absent from the southeastern lowland section.
Ranges from Florida to Texas, north to New York,

406 *Fimbristylis VahlII*407 *Fimbristylis autumnalis*408 *Scirpus verecundus*

New Jersey, Ontario, Michigan, Illinois, and Missouri.

This species is a characteristic plant of upland prairies and exposed rocky glades, where it withstands extremes of temperature and severe drouth. Fernald (*Gray's Manual*, eighth edition, p. 261. 1950) attempted to separate two variants of this group on the basis of soil differences. The 'acid or subacid habitats' which he attributes to *F. Drummondii* (the plants in Missouri), does not cover the range of soils variations encountered among the Missouri plants as they are more frequently found on alkaline limestone and other calcareous glades, as well as on acidic sandstone or chert rocks.

The spikelets are raised on a slender elongated mostly naked culm often 70 cm. tall, standing higher than the narrow leaves which are densely tufted at the base. The leaves and culms may be glabrous or more or less hairy. The spikelets may be sessile in the early stages of flowering to eventually stalked as the flowering stage develops.

Svenson (*North Am. Fl.* 18, part 9: 551. 1957) has combined this and other related variations under *Fimbristylis spadicea* (L.) Vahl. He is of the opinion that, although these variants differ in certain characters, such as luster and pubescence of scales, spikelet shape and length, and width of leaves, they are all held together by the same type of achene. In the present treatment the name *Fimbristylis caroliniana* is used for those plants having pubescent scales of the spikelets.

2. ***Fimbristylis dichotoma* (L.) Vahl** Map 405

Fimbristylis Baldwiniana (Schultes) Torr. [G]

Fimbristylis annua (All.) R. & S. [BB]

Fimbristylis laxa Vahl [P & S]

Flowers June–October.

Occurs on sandy prairies, moist sandy open ground,

margins of ponds, moist places in glades, and on gravel and sand bars along streams, usually in acid soils. Southern and central Missouri, mainly in the southwestern third of the state, north to Cooper and Jackson counties, locally east to Madison, Mississippi, and Dunklin counties.

Ranges from Florida to Texas and Arizona, north to Pennsylvania, Illinois, Missouri, and Oklahoma; also in Mexico, Central and South America, the West Indies, and in the Old World tropics.

The spikelets have a shape similar to those of *F. caroliniana*, but the plants are generally much shorter, averaging 1–3 dm. tall, the leaves are flat instead of becoming involute (margins rolled in) as in *F. caroliniana*, and the achenes have a different color and markings.

3. ***Fimbristylis VahlII* (Lam.) Link** Map 406

Flowers July–October.

Occurs in moist sandy open ground and along sandy margins of ponds, in southern Missouri north to Wayne and Barton counties.

Ranges from Florida to Texas, north to North Carolina and Missouri; also in California, Pennsylvania (introduced), and Central and South America.

The plants occur as small grass-like tufts usually only 3–10 cm. tall with hair-like leaves and involucre bracts, which greatly exceed the small clusters of spikelets. The latter, in contrast to the total height of the leaves, appear almost near the surface of the ground.

4. ***Fimbristylis autumnalis* (L.) R. & S.** Map 407

Fimbristylis autumnalis var. *mucronulata* (Michx.)

Fern. [G]

Fimbristylis mucronulata (Michx.) Blake [P & S]

Flowers June–October.

PLATE NO. 73

Occurs in sandy fields, sandy open ground, moist sand and gravel bars, wet muddy shores of streams and ponds, and wet places in prairies and glades. Southern and central Missouri north to Lincoln, Callaway, and Jackson counties, and locally northwest in Holt County.

Ranges from Quebec and Maine to Ontario and Minnesota, south to Florida and Texas, Central America, and Cuba.

Missouri material has been divided into *F. autumnalis* var. *autumnalis* and *F. autumnalis* var. *mucronulata* (Michx.) Fern. with the following key differences emphasizing the main contrasts:

Spikelets ovate-lanceolate or lance-elliptic;

scales of spikelets with free slender tips; spikelets simple to compound, 1-50. . . . F. AUTUMNALIS
var. AUTUMNALIS

Spikelets linear-cylindric to narrowly fusiform; scales of spikelets with tips more closely appressed; spikelets compound, 5-100 . F. AUTUMNALIS
var. MUCRONULATA

These differences do not appear to be correlated well enough to be applicable to collected material, and are interpreted in the present work as modifications occurring as a normal amount of variation influenced partly, no doubt, by changing environmental conditions. Similar conclusions have been drawn or indicated by Deam (*Fl. Indiana* p. 205, 1940) and by Gleason (*New Ill. Fl.* 1: 269, 1952).

6. *Scirpus* L. Bulrush

Annuals or perennials with leafy or leafless culms, the leaves sometimes represented by sheaths only. Flowers of 2-3 stamens, a 2-3-cleft style, the base of which is deciduous (falls off), and 1-8 bristles, or these not present.

- a. Tip of each culm (stem) ends in only 1 spikelet without any elongated bract 1. *S. VERECUNDUS*
- a. Tip of each culm (stem) ends in 1 or more leaf-like bracts with 1 or more spikelets b
- b. The culm (stem) ends in 1 erect bract (which resembles a continuation of the culm), the inflorescence thus appearing to originate from the side of the culm (stem); culms (stems) without leaves, or leaves inconspicuous, or leafy only near the base c
- c. All spikelets without or nearly without a stalk, appearing to come directly from the culm or erect involucre bract; culms either 3-angled, or, if terete, 3 mm. or less thick at base, and often less than 1 meter tall, but also taller d
- d. Culms (stems) terete (cylindrical, or with rounded sides, or round or nearly round in cross-section); perennial plants either growing in the water, or soft-based annuals with fibrous roots and slender tufts of culms averaging 5-35 cm. tall e
- e. Perennial plants with culms usually submerged and growing in the water; flowers with bristles at base of achene; culms solitary or scattered, with occasional thickened areas (nodulose), usually 30-120 cm. tall 4. *S. SUBTERMINALIS*
- e. Annual plants growing in dry or moist soil; flowers without bristles; culms without thickened areas, in tufts usually 5-35 cm. tall f
- f. Culms hair-like, 1 mm. or less thick; style 3-cleft; achene brown, 3-sided; scales of spikelet greenish, prominently keeled; spikelets 1-3 2. *S. KOIOLEPIS*
- f. Culms stouter, usually 1.5-3 mm. thick; style 2-cleft; achene black (when ripe), flattened, 2-sided; scales of spikelet mostly brown with green keel, slightly keeled; spikelets mostly 2-7 (rarely 1) 3. *S. HALLII*
- d. Culms (stems) 3-sided; perennial plants with creeping rhizomes with culms solitary or scattered, averaging 40-150 cm. tall g
- g. Style 3-cleft (for exceptional 3-cleft style of *S. americanus* var. *polyphyllus*, refer to 2nd g.); achene 3-sided (trigonous), with a long tip (beak) about $\frac{1}{4}$ length of achene; culms bluntly 3-angled, 0.5-2 mm. thick at summit; scales of spikelets pale or yellow-brown to straw-color, entire, ovate-lanceolate; leaves with scattered thickened areas (nodulose) 5. *S. TORREYI*
- g. Style 2-cleft (rarely 3-cleft in *S. americanus* var. *polyphyllus*); achene 2-sided, with a very short tip (beak) about $\frac{1}{10}$ - $\frac{1}{9}$ length of achene; culms sharply 3-angled, mostly 2-10 mm. thick at summit; scales of spikelet reddish- or chestnut-brown, with fringed or irregularly cut margins, ovate to orbicular; leaves without scattered thickened areas h
- h. Common species; upper leaf-blade 2-9 mm. wide at base, sharp-pointed; erect stem-like involucre bract linear, 2-15 cm. long, acute; culm without winged angles, firm, solid, its sides nearly flat or only slightly concave (sunken in middle), mostly 2-6 mm.

- thick at the upper leaf-sheath; scales of spikelet prominently and abruptly tipped (mucronate) 6. *S. AMERICANUS*
- h. Rare species; upper leaf-blade 8–15 mm. wide at base, blunt-tipped; erect stem-like involucre bract narrowly triangular, 1–3.5 cm. long, blunt; culm with winged angles, soft, hollow, its sides deeply concave (as if sunken in the middle), mostly 4–10 mm. thick at the upper leaf-sheath; scales of spikelet inconspicuously tipped 7. *S. OLNEYI*
- c. Spikelets separated from the culm (stem) and erect involucre bract by branched or unbranched stalks; culms (stems) terete, or, if 3-sided, 3–20 mm. thick at base, or mostly 1–2 meters tall i
- i. Rare species of sink-hole ponds, known only from Oregon Co.; culm 3-sided; scales of spikelets pale brown or greenish; basal leaf-sheath with a long and developed leaf-blade; stem-like involucre bract 3-angled; main part (body) of achene 4 mm. long. 11. *S. ETUBERCULATUS*
- i. Common species of ponds and sloughs; culm terete or nearly terete (cylindrical or with curved or rounded sides, round in cross-section); scales of spikelets reddish- or chestnut-brown, or pale brown to greenish; basal leaf-sheath lacking a developed leaf-blade; stem-like involucre bract terete (cylindrical and rounded in cross-section); main part (body) of achene 1.7–2.8 mm. long j
- j. Spikelets ovoid, usually 4–10 mm. (up to 15) long; scales of spikelets about as long as or only slightly longer than achenes, the margins with fine white hairs; midrib of scales prominently thickened and green, projecting noticeably beyond scale as a tip; achenes 1.5–2.3 mm. long 8. *S. VALIDUS* var. *CREBER*
- j. Spikelets more elongated, ranging from linear-cylindrical or narrowly ellipsoidal to lanceolate or narrowly ovoid, mostly 8–23 mm. long (rarely shorter); scales of spikelets much longer than the achenes, either glabrous or with red dots and glandular-hairy toward summit; midrib of scales either not prominent or not projecting noticeably beyond summit of scale; achenes averaging 2–3 mm. long k
- k. Achene 3-angled (trigonous); style 3-cleft; scales of spikelet glabrous, pale brown, drab, or greenish; bristles shorter than achene; spikelets lanceolate or narrowly ellipsoidal, tapering to a somewhat pointed tip 10. *S. HETEROCHAETUS*
- k. Achene 2-sided; style usually 2-cleft, rarely 3-cleft; scales of spikelets red-dotted, with a glandular-hairy area toward summit, reddish-brown to dark brown; bristles equaling or slightly shorter than achene; spikelets linear-cylindrical to narrowly ovoid, somewhat rounded or blunt at tip 9. *S. ACUTUS*
- b. The culm (stem) ends in 2 or more leaf-like spreading bracts, the inflorescence thus terminating the culm; culms with several or many well-developed leaves l
- l. Culms (stems) sharply 3-angled; spikelets 10–40 mm. long, 5–11 mm. thick; achenes 3–5 mm. long m
- m. Common plant of fresh water ponds, sloughs, and swamps; leaves usually more than 6 on a culm (stem); leaves of involucre 3–5; summit of leaf-sheath with a rounded or convex membrane; style 3-cleft; achenes 4–5 mm. long, 3-sided; bristles 6, persistent, equaling or nearly equaling achene 12. *S. FLUVIATILIS*
- m. Rare plant of saline or alkaline soils around salt or sulfur springs, rarely elsewhere; leaves usually 3–6 on a culm (stem); leaves of involucre 1–2 (rarely 3); summit of leaf-sheath with a truncate (cut straight across) or concave (shallowly U-shaped with sloping sides) membrane; style usually 2-cleft; achenes 2.8–3.8 mm. long, mostly 2-sided; bristles 2–6, weak, eventually falling from and shorter than the achene 13. *S. PALUDOSUS*
- l. Culms (stems) obtusely (bluntly) angled; spikelets 2–10 mm. long, 1–4 mm. thick (excluding bristles); achenes 0.7–1.3 mm. long n
- n. Bristles lacking in flowers 14c. *S. ATROVIRENS* var. *GEORGIANUS*
- n. Bristles present, minute or conspicuous o
- o. Bristles in flower and fruit with tiny barbs directed downward (retroarsely) (do not confuse with the smooth filaments which may remain attached at first); stems either solitary or few in a clump from scaly stolons p
- p. Common throughout Missouri; 4–9 leaves on each culm (stem) not in a 2-ranked arrangement, averaging 10–20 mm. (rarely 5) wide; bristles somewhat shorter or slightly longer than achene; spikelets pale to dark brown or lead-colored. 14a. *S. ATROVIRENS* var. *ATROVIRENS*
- p. Known only from swampy meadows in the southeastern Missouri Ozarks; 10–20 or more leaves regularly arranged in 2 ranks (distichous) on each culm (stem),

409 *Scirpus koilolepis*410 *Scirpus Hallii*411 *Scirpus subterminalis*

averaging 3–8 mm. (rarely 10) wide; bristles about 2 times the length of the achene; spikelets reddish-brown. 15. *S. POLYPHYLLUS*

- o. Bristles in flower and fruit smooth, or, if barbed, the barbs few and upwardly ascending (do not confuse with the filaments which may remain attached at first); stems growing from usually large clumps, not producing stolons q

- q. Bristles *at maturity* scarcely longer than the scales of the spikelets; spikelets linear-cylindrical (finger-shaped), $2\frac{1}{2}$ –4 times longer than broad; each spikelet alone on a pedicel (stalk) or not clustered with other spikelets r

- r. Rare plant of southeastern Missouri swamplands; 10–20 leaves regularly arranged in 2 ranks (distichous) on each culm (stem), the internodes short and leaf-sheaths nearly overlapping; lower branches of inflorescence widely spreading; scales of spikelet obtuse (blunt), the midrib not projecting as a conspicuous tip; bristles shorter than the achene. 16. *S. DIVARICATUS*

- r. Common plant throughout Missouri; usually 5–10 leaves present on each culm (stem) and not in regular distichous (2-ranked) arrangement, the internodes elongated and leaf-sheaths not overlapping; lower and other branches of inflorescence ascending or upwardly spreading; scales of spikelet conspicuously pointed with the green midrib projecting; bristles about twice the length of the achene 17. *S. LINEATUS*

- q. Bristles *at maturity* much longer than the scales of the spikelets, conspicuously curled or twisted, giving a somewhat woolly appearance; spikelets ovoid or nearly globe-shaped, nearly as long as broad or at most $1\frac{1}{2}$ times longer than broad; spikelets usually in clusters or grouped together, or, in *S. rubricosus* with the lateral spikelets of each ultimate group on separate stalks s

- s. Spikelets all or nearly all in sessile clusters, without stalks for any one spikelet in an ultimate group 18. *S. CYPERINUS*

- s. The lateral spikelet of each ultimate group with its own stalk, the central one of each ultimate group sessile (without a stalk) 19. *S. RUBRICOSUS*

1. ***Scirpus verecundus* Fern.**

Map 408

Scirpus planifolius Muhl. [P & S]

Flowers late April–June.

Occurs on dry rocky wooded slopes, in acid soils of sandstone or chert areas. Infrequently collected, known from only a few Ozark counties north to Washington County and west to Douglas County.

Ranges from Maine to Virginia, west to Ohio, Kentucky, and Missouri.

This plant, growing in characteristic tufts with narrow basal leaves 1–2 mm. wide and slender culms, may be mistaken in the field at first for *Carex artitecta*

or some similar species, which it resembles vegetatively, as well as occupying a similar type of dry acid-soil woodland. Careful search in acid soils of dry woodlands should increase its distribution to include a majority of Ozark counties.

2. ***Scirpus koilolepis* (Steud.) Gleason** Map 409
Scirpus carinatus Gray [P & S]

Flowers April–June.

Occurs in sandy open ground along small streams in prairies, in moist sandy soil, and on sandstone and chert glades and barrens. Southern Missouri, where it

PLATE NO. 74

412 *Scirpus Torreyi*413 • *Scirpus americanus* var. *americanus*
□ *Scirpus americanus* var. *polyphyllus*414 *Scirpus Olneyi*

occurs in two distinct areas: (1) southwestern Missouri and (2) southeastern Missouri. It is absent from most of the Ozark section.

Ranges from Alabama to Mexico, north to Tennessee, Missouri, Oklahoma, and California.

The boat-shaped and sharply keeled scales of the spikelets in this species are quite unlike those of any other species of the genus. Plants average about 10 cm. in height, varying from 5 to 18 cm. tall.

3. ***Scirpus Hallii* Gray** Map 410
Flowers August–October.

Known at present only from a sink-hole pond in Howell County, southern Missouri (pond near Adobosee Pond, T22N, R7W, north part of sect. 1, 9 mi. southeast of West Plains, September 4, 1949, *Steyermark 69122*). Previously known only from a pond in St. Louis County, where now exterminated.

This species occurs as a rare and local plant from Florida and Georgia to Texas and Mexico; Massachusetts, Illinois, and Missouri.

This species was abundant where it occurred at the only known Missouri station. The scales of the spikelet are conspicuously pointed, the outermost one prolonged as a narrow involucre leaf.

4. ***Scirpus subterminalis* Torr.** Map 411
Flowers July–October.

Known only from Oregon County, southern Missouri (in still water of White's Creek, Irish Wilderness, Clark National Forest, T24N, R2W, sect. 17, 4 mi. south of Wilderness, July 20, 1936, *Steyermark 12054*).

Ranges from Newfoundland to Ontario, south to South Carolina, Georgia, Michigan, Indiana, Illinois, and Missouri; also Alaska to Montana, Idaho, and Oregon.

This unusual aquatic perennial has slender soft

rhizomes and threadlike, very long, delicate submerged leaves. The culms likewise, are threadlike. The solitary sessile spikelet is attached to the side of the single, erect, threadlike involucre bract. At the single station known in Missouri it occurred in two feet of still water.

The occurrence of this northern species isolated in a remote section of the southern Ozark region is an example of a relict plant which probably migrated southward to the Ozarks in Pleistocene (Ice Age) times during a relatively cooler period that prevailed, and, following the retreat of the glaciers northward, continued to survive to the present time in a less favorable environment, where this species now just manages to exist, and not spread. Such habitats should be preserved in their natural condition for the important geological and geographical history signified by the occurrence of their relict survivors.

5. ***Scirpus Torreyi* Olney** Map 412
Flowers June–September.

Known only from a sink-hole pond in Laclede County, southern Missouri (around deep part of margin of upland sink-hole pond along highway 32, sect. 6, 1¼ mi. north of Lynchburg, June 23, 1939, *Steyermark 27146*).

Ranges from New Brunswick to Manitoba, south to New Jersey, Pennsylvania, Kentucky, Indiana, Illinois, Missouri, and South Dakota.

The occurrence of this species at the single Missouri station is another example of the remarkable isolation of several rare sedges known in the state only from sink-hole pond habitats.

6. ***Scirpus americanus* Pers.** Chairmaker's Rush, Three Square Map 413
Flowers late May–September.

Occurs along gravel bars of streams, sandy and

PLATE NO. 75

415 *Scirpus validus* var. *creber* (Great Bulrush)416 *Scirpus acutus* (Great Bulrush)417 *Scirpus heterochaetus* (Great Bulrush)

muddy margins of ponds, sloughs, swamps, ditches, and low wet woods. Frequent in southern and central Missouri north locally to Marion, Macon, and Holt counties; apparently absent from most of northern Missouri.

Ranges from Florida to Texas, north to Newfoundland, Quebec, Ontario, Michigan, Wisconsin, and Nebraska; also Eurasia. Numerous varieties are encountered in western United States, Mexico, Central and South America.

Most of the plants in Missouri have the style normally 2-cleft, ovoid spikelets 6–13 mm. long, averaging 2–2½ times longer than broad, culms averaging 60–100 cm. tall and 3–4 mm. thick, and an involucre bract averaging 4–10 cm. long, and are *S. americanus* var. *americanus*. Plants with the style normally 3-cleft and with unusually long and narrow linear-cylindrical spikelets 15–23 cm. long and 4–5 times longer than broad, short dwarfed culms 15–60 cm. tall and 1–1.5 mm. thick with involucre bract 2–3.5 cm. long have been found in Jasper County, southwestern Missouri (Steyermark 86153; Palmer 67476) and are distinguished as var. *polyphyllus* (Boeckl.) Beetle. The achenes in this dwarf variation are mostly 2.25–2.5 mm. long, instead of 2.5–3 mm. long as in typical *S. americanus* var. *americanus*.

7. ***Scirpus Olneyi* Gray**

Map 414

Flowers June–September.

Known only from Jefferson County, eastern Missouri (sulphur spring brackish morass, August 10, 1866, Engelmann).

Ranges along the coast from Florida to Mexico, north to New Hampshire and Nova Scotia; inland in New York, Ohio, Michigan, Missouri, Idaho, Oregon; also in the West Indies, Central and South America.

This species has hollow culms, an exception to the usual character of Cyperaceae.

8. ***Scirpus validus* Vahl var. *creber* Fern.**

Great Bulrush

Map 415

Scirpus validus of auth., not Vahl [P & S, BB]

Flowers late May–September.

Occurs in shallow water and in wet ground of sloughs, ponds, rivers, oxbow lakes of river flood plains, and in wet prairies. Found throughout most of Missouri, the common bulrush of the Ozark section; apparently absent from sectors of northern Missouri.

Ranges from Newfoundland to Alaska, south to New York, Georgia, Tennessee, Missouri, Oklahoma, Texas, New Mexico, and California.

Typical *S. validus* var. *validus* ranges from South and Central America, the West Indies, and Mexico to South Carolina.

This plant, like *S. acutus* and *S. heterochaetus*, the other species with long whiplike culms, usually occurs in large colonies. In some Missouri specimens the style is 3-cleft, although the 2-cleft condition is more frequent.

In this and the following species (*S. acutus*), the dried beaten rootstocks are used by some Indian tribes as meal for bread, while the young tip of the underground rootstock is edible and reputed to serve as a thirst-quencher; the boiled young roots yield a sweet syrup. The achenes are also used for food.

9. ***Scirpus acutus* Muhl. Great Bulrush** Map 416

Flowers late May–September.

Occurs along the larger rivers (Missouri, Grand and its tributaries) of northwestern and west-central Missouri, south to Jackson, Lafayette, Saline, and Osage counties, locally east to Ralls County and locally south in Oregon County. Absent from practically the entire Ozark sector, as well as the southeastern lowland and southwestern unglaciated prairie sections.

Ranges from Newfoundland to British Columbia,

PLATE NO. 76

418 *Scirpus etuberculatus*419 *Scirpus fluviatilis* (River Bulrush)420 *Scirpus paludosus* var. *paludosus* (Bayonet Grass)

south to New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Missouri, Oklahoma, Texas, New Mexico, Arizona, and California.

This species is sometimes confused with *S. validus* var. *creber* and *S. heterochaetus*. From the former it differs in having longer, more linear-cylindrical spikelets and from the latter in 2- instead of 3-sided achenes. The culms (stems) of *S. acutus* are usually harder and firmer, more slender, and of a darker green shade than those of *S. validus* var. *creber*. For this reason, *S. acutus* is often known as Hard-stem Bulrush as contrasted with *S. validus* var. *creber*, the Soft-stem Bulrush.

10. *Scirpus heterochaetus* Chase

Great Bulrush

Map 417

Sometimes called slender bulrush.

Flowers late May–September.

Occurs in shallow water and in wet ground in the border of ponds, sloughs, rivers, and oxbow lakes of river flood plains. Scattered over the state, but probably of wider distribution with more intensive collecting.

Ranges from Quebec to Massachusetts and New York; from Wisconsin and Illinois to North Dakota, south to Kentucky, Missouri, and Oklahoma; and from Idaho and Washington to Oregon.

Some representative Missouri collections are from Laclede (*George Moore*), Texas (*Steyermark 23292*), and St. Charles (*Von Schrenk*) counties.

The spikelets are paler brown or even straw-colored as contrasted with the reddish-or chestnut-brown or dark brown colors found in *S. acutus* and *S. validus* var. *creber*.

11. *Scirpus etuberculatus* (Steud.) Ktze. Map 418

Flowers June–October.

Known only from a natural sink-hole pond in

Oregon County, southern Missouri (Tupelo Gum Pond, T25N, R4W, sect. 4, 8 mi. west of New Liberty, October 3, 1948, *Steyermark 66629*).

Ranges from Florida to Louisiana, north to Delaware and Missouri.

This is one of the notable remnant species of the Atlantic and gulf coastal plain flora restricted to sink-hole ponds in the Ozarks, where it, like some other species in the state restricted to such ponds, indicates the former, more widespread, though ancient coastal plain conditions that prevailed before the last Tertiary uplift of the Ozarks. The Ozark sink-hole ponds contain the last survivors of the original pre-Tertiary coastal plain flora that covered the present Ozark area when it was a low-lying peneplain.

12. *Scirpus fluviatilis* (Torr.) Gray

River Bulrush

Map 419

Flowers May–September.

Occurs in shallow water and wet mud of sloughs, swamps, oxbow lakes in river flood plains, and along the larger rivers, where it occupies stretches along the Missouri, Grand and its tributaries, and Mississippi rivers, mostly in northern and central Missouri. Absent from the greater part of the Ozark section.

Ranges from Quebec to Saskatchewan and Washington, south to Delaware, Maryland, Virginia, Pennsylvania, Ohio, Indiana, Illinois, Missouri, Kansas, New Mexico, and California.

This species usually occurs in dense colonies which are frequently all vegetative and without flowers. The leaf-blades and culms are sharp-edged and can easily cut the flesh. The culms are thicker and the leaf-blades wider than in any of the other Missouri species; these characters, plus the dense colonial habit of the culms, leafy to the summit, are unmistakable field marks of identification. The thick creeping rootstocks bear solid cormlike enlargements.

PLATE NO. 77

13. ***Scirpus paludosus*** Nels. var. ***paludosus***

Bayonet Grass, Prairie Bulrush Map 420

Scirpus campestris var. *paludosus* (Nels.) Fern.*Scirpus paludosus* Nels. [G]*Scirpus maritimus* L., var. *paludosus* (A. Nels.) Gl. [BB]*Scirpus campestris* Britton, not Roth [P & S]

Flowers June–October.

Occurs in wet salt-impregnated or alkaline ground around salt springs in Saline County (wet swaley ground bordering salt spring and spring branch of Elk Lick Spring, in valley of Heath's Creek, sect. 17, 3 mi. southwest of Ridge Prairie, October 6, 1938, *Steyermark* 21587), and in alkaline sandy mud along an oxbow lake of Missouri River in Holt County (sands along west end of Big Lake State Park, September 2, 1934, *Steyermark* 15141).

Ranges from Minnesota, Iowa, Missouri, Oklahoma, and Texas, west to British Columbia, California, and Mexico.

At the Saline County station this species was associated with other saline to brackish water-inhabiting species, as *Distichlis spicata*, *Eleocharis parvula*, and *Typha angustifolia*.

Although often a robust and tall-growing species elsewhere in its range, at the Missouri stations it is usually less than a meter tall, and in the Holt Co. collection the plants are only 15–25 cm. tall. It most closely resembles *S. fluviatilis*, and, like that species, has the midribs of the spikelet scales prolonged into conspicuous awns.

The enlarged cormlike parts of the rootstock of this species are reported to serve as starchy food for some of the western Indians. The related species, *S. fluviatilis*, probably may, likewise, have similar use.

14. ***Scirpus atrovirens*** Willd.

Common Bulrush

Map 421

Flowers late May–September.

Occurs in wet ground bordering lakes, sloughs, streams, and ditches. Throughout Missouri. So far as records indicate, this is the commonest species of Bulrush in the state.

Missouri material may be divided into the following variations:

- a. Scales of the spikelet prolonged at the tip to a long awn; scales narrowly ovate, 2–3 mm. long . . . 14d. *S. ATROVIRENS* var. *PALLIDUS*
- a. Scales of the spikelet with a short mucro (extension of midrib) at the tip; scales broadly ovate, 1–2 mm. long b
- b. Dried leaf-blades and leaf-sheaths of lower

leaves only faintly, if at all, marked with short cross-partitions or thickenings, mainly 5–10 mm. wide; bristles not present or shorter than the achenes . . . 14c. *S. ATROVIRENS* var. *GEORGIANUS*

- b. Dried leaf-blades and leaf-sheaths of the lower leaves with conspicuous short cross-mark or thickenings mostly 10–20 mm. wide; bristles slightly longer than the achenes c

c. Bunches of spikelets massed together in 1 or more dense heads; branches (rays) supporting the inflorescence very much shortened 14b. *S. ATROVIRENS* var. *ATROVIRENS* f. *SYCHNOCEPHALUS*

- c. Bunches of spikelets in numerous separate groups; branches (rays) supporting the inflorescence conspicuous, elongated, at least most of them 2–5 cm. long .

14a. *S. ATROVIRENS* var. *ATROVIRENS* f. *ATROVIRENS*

14a. ***Scirpus atrovirens*** var. ***atrovirens*** f.***atrovirens***

Map 421

The common variety throughout Missouri in nearly every county.

Ranges from Quebec to Saskatchewan, south to Georgia, Tennessee, Arkansas, and Kansas.

14b. ***Scirpus atrovirens*** var. ***atrovirens*** f.***sychnocephalus*** (S. N. Cowles) Blake

Map 421

Scattered in the range of var. *atrovirens*. A representative collection is *Sparling* from Livingston County. Probably of more frequent occurrence.

14c. ***Scirpus atrovirens*** var. ***georgianus***

(Harper) Fern.

Map 421

Known from Iron (open bog near Lopez, September 4, 1926, *Palmer* 31550) and Butler (low woods along Mud Creek, T26N, R7E, sect. 20, 2 mi. northwest of Rombauer, June 30, 1936, *Steyermark* 11312) counties in southeast Missouri.

Ranges from Newfoundland to Ontario and Minnesota, south to Georgia, Tennessee, and Arkansas.

The spikelets in this variety are often smaller (2–3 mm. long instead of 3.5 mm. or more) and in less crowded clusters (usually less than 7 mm. in diameter) than those of *S. atrovirens* var. *atrovirens*.

14d. ***Scirpus atrovirens*** var. ***pallidus*** Britton

Map 421

Scirpus pallidus (Britt.) Fern. [G, P & S]

Known from Jackson and Dekalb counties, western

 421 □ *Scirpus atrovirens* var. *georgianus*
 421 † *Scirpus atrovirens* var. *pallidus*

Missouri. The Jasper County collection (Palmer 2128), cited in Palmer & Steyermark's *Catalogue* (p. 485) is a misidentified specimen of *S. atrovirens* var. *atrovirens*. The following collections from Jackson County in the Gray Herbarium were referred to this variety by Fernald: *Bush* 587, Courtney, June 22, 1895; *Bush* 374, July 11, 1893. The scales of the spikelets in these specimens are only 1.3–1.6 mm. long and the awns are not particularly long-setulose. These specimens are here referred instead to *S. atrovirens* var. *atrovirens*.

The spikelets of *S. atrovirens* change color materially during their development. In the young bud or early flowering stage, the scales are pale or greenish brown with dull green midribs. In late stages of flowering and fruit the scales turn a dark or chocolate brown with some black marks.

15. ***Scirpus polyphyllus* Vahl** Map 422
 Flowers June–September.

Occurs in calcareous swampy meadows in the Ozark section of southeastern Missouri, where known only from Bollinger, Stoddard, Madison, and Reynolds (Steyermark 72002, 72041) counties.

Ranges from Massachusetts and New York to Ohio, Indiana, and Illinois, south to Georgia, Tennessee, and Missouri.

This rare species is localized in swampy meadows fed by calcareous springs in small valleys bordering the smaller streams. Before such habitats are drained for agriculture or otherwise destroyed by farming or other disturbances, it may eventually be found to have a somewhat greater range of distribution in the eastern section of the Ozarks.

16. ***Scirpus divaricatus* Ell.** Map 423
 Flowers June–September.

Occurs in swamps and low wet woodland of the southeastern lowland section of the state in Dunklin, Butler, and Ripley counties, and introduced in St. Louis County along a ditch by railroad tracks (in ditch along track of Terminal R. R. Assoc. at Brown Ave. west of Union Blvd., St. Louis, July 1, 1956, Muehlenbach 980). Another specimen from the World's Fair was also collected in St. Louis County (August 18, 1892, *Bush* 2769).

Ranges from Florida to Louisiana, north to Virginia and southeastern Missouri.

Young leafy plants and buds are often produced in the inflorescences and leaf-axils of this species.

17. ***Scirpus lineatus* Michx.** Map 424
 Flowers May–August.

Occurs in wet prairies, wet limestone glades and ledges, roadside ditches, and borders of streams and ponds. Throughout Missouri, except in the extreme northwestern section, where not yet recorded.

Ranges from Maine to Minnesota, south to Florida and Texas, and in Oregon.

In early stages of development the spikelets are scarcely stalked and paler brown, scarcely protruding from the upper leaf-sheaths and involucral bracts, but as they become more mature, they take on a reddish-brown or brick color and are conspicuously exerted on long pedicels of the drooping rays.

18. ***Scirpus cyperinus* (L.) Kunth** Map 425
 Flowers July–October.

Occurs in swamps, sloughs, and borders of oxbow lakes in river flood plains. Eastern and northern Missouri west to Caldwell County.

The Missouri material falls into the following two categories:

PLATE NO. 79

424 *Scirpus lineatus*425 • *Scirpus cyperinus* var. *cyperinus*
426 □ *Scirpus cyperinus* var. *pelius*426 *Scirpus rubricosus*

Involucels (the small colored bracts at the place separating the main rays or branches of the inflorescence from the more slender spikelet-bearing branches) reddish-brown; scales of spikelets reddish-brown; bristles rust-colored . . .

18a. *S. CYPERINUS* var. *CYPERINUS*

Involucels blackish or drab, without reddish-brown tinge; scales of spikelets with little or no reddish color; bristles smoky or gray-drab color

18b. *S. CYPERINUS* var. *PELIUS*

18a. ***Scirpus cyperinus* var. *cyperinus*** Map 425

The commoner variety of this species in Missouri.

Ranges from North Carolina to Oklahoma, north to New England, New York, Ohio, Indiana, Illinois, and Iowa.

18b. ***Scirpus cyperinus* var. *pelius*** Fern. Map 425

Known only from Butler County, southeastern Missouri (swamps, October 16, 1905, *Bush 3707*).

Ranges from Newfoundland to Minnesota, south to Maryland, West Virginia, Ohio, Illinois, Iowa, and Missouri.

19. ***Scirpus rubricosus*** Fern.

Map 426

Scirpus Eriophorum Michx.

Scirpus pedicellatus [of P & S], not Fern.

Scirpus cyperinus [of BB] in part

Flowers July–October.

Occurs in swampy meadows along streams, swamps, sloughs, and borders of oxbow lakes in river flood plains. Northern and eastern Missouri.

Specimens from Putnam and Adair counties, cited in Palmer and Steyermark's *Catalogue* (p. 485) as *S. pedicellatus* Fern., are misidentified specimens of *S. rubricosus*. There is no authentic material of *S. pedicellatus* known from the state.

Gleason (*Ill. Fl.* 1: 276. 1952) has combined *S. Eriophorum*, *S. rubricosus*, *S. pedicellatus*, and *S. atrocinctus* Fern. under *Scirpus cyperinus*, which he regards as a polymorphic species varying in the color of the scales and involucre, length of rays, peduncles, and spikelets, and width of leaves. Until more experimental work is at hand to test the soundness of this viewpoint, the present treatment is maintaining both *S. Eriophorum* and *S. rubricosus* in the light of Fernald's previous detailed studies.

7. ***Fuirena*** Rottb. Umbrella Grass

Perennial plants (in the local species) with leafy culms, more or less pubescent leaf-sheaths, and flat leaf-blades. Spikelets in close clusters with a leaflike bract at their base. Flowers of 3 stamens, a 3-cleft style, and a 3-sided achene surrounded by 3 bristles alternating (in our species) with 3 stalked broadened scales.

Fuirena simplex Vahl

Map 427

Flowers July–October.

Occurs along gravel bars, wet margins and moist limestone banks of streams, swampy open and wooded ground of spring branches, and muddy margins of oxbow lakes of river flood plains. Except for two localities along the Missouri River in western Missouri in

Jackson and Holt (Big Lake State Park, September 1, 1934, *Steyermark 15094*) counties, this species is restricted to the Ozark section of the state, extending north to Ste. Genevieve, Washington, Crawford, Miller, and Camden counties, west to Laclede, Webster, Christian, and Taney counties.

Ranges from northwestern Missouri and Nebraska

1

2

3

4

427 *Fuirena simplex*428 *Hemicarpha Drummondii*429 *Hemicarpha micrantha*

south to Oklahoma, Texas, and Mexico; also in Central America and Cuba.

Excluded species

***Fuirena squarrosa* Michx.**

B. F. Bush (in personal communication) wrote that

he had found this species (reported by him as *F. hispida* Ell.) at Anderson, McDonald County. No specimen of this collection has ever been found, nor is the species cited for Missouri in Svenson's recent treatment in *North America Flora* 18: 506. 1957. Therefore, the species is excluded from the present work.

8. *Hemicarpha* Nees

Dwarf annual tufted plants, the hairlike culms bearing 2 hair-like leaves at the base, only the upper one with a short leaf-blade. Spikelets very small, 1–3 in a stalkless cluster surpassed by 2 or 3 hairlike involucre bracts. Flowers of 1 stamen, a 2-cleft style and no bristles; in addition to the larger, pointed, spirally overlapping, outer scales, a minute inner scale occurs on the side of the flower next to the axis of the spikelet.

Main outer scales with a long curved awn almost equaling the length of the scale itself; small inner scale equaling and partly inclosing the achene; mature achene obovate, compressed, black . . . 1. *H. DRUMMONDII*
Main outer scales with a short extended tip much shorter than the length of the scale itself; small inner scale much shorter than the achene, often absent; mature achene cylindrical, brown . . . 2. *H. MICRANTHA*

1. ***Hemicarpha Drummondii* Nees** Map 428

Hemicarpha aristulata (Coville) Smyth [G]

Hemicarpha micrantha var. *aristulata* Coville [P & S, BB]

Flowers July–October.

Occurs along wet sandy margins of ponds and streams, and in wet depressions of glades. Rare and scattered, in St. Louis, Stone, Barry, Clay, and Buchanan counties.

Ranges from Ohio, Minnesota, Iowa, and Missouri, west to the Pacific states.

The type locality for this species is St. Louis, Missouri.

2. ***Hemicarpha micrantha* (Vahl) Pax.** Map 429

Flowers July–October.

Occurs on sand bars along streams, muddy borders of ponds and sloughs, and wet depressions in glades of sandstone, chert, or granite. Mostly found in southern and central Missouri, and locally north in Clark and Holt counties.

Ranges from Maine to Ontario and Minnesota, south to Florida, Nebraska, and Kansas; Texas, New Mexico, Arizona, and the Pacific states; also in Mexico, Central and South America, and the West Indies.

9. *Rhynchospora* Vahl Beak-rush

Perennial plants (in the local species) with triangular leafy culms. Lower scales of spikelet usually empty, the uppermost ones usually staminate (with stamens only). Stamens 3, when present. Style 2-cleft. Achene globe-shaped with 2 sides or flattened, crowned by a conspicuous beak of the persistent hardened base or portion of the style. Perianth consisting of 6–20 bristles or these absent.

PLATE NO. 81

430 *Rhynchospora macrostachya* var. *macrostachya*
(Horned Rush)431 *Rhynchospora corniculata* var. *corniculata* (Horned
Rush)432 *Rhynchospora capitellata* f. *capitellata* (False Bog Rush)

- a. Leaf-blades and culms (stems) hair-like or very narrowly linear, 0.2–0.4 mm. wide; leaf-blades with margins rolled in (involute); plants of moist limestone ledges and calcareous wet meadows or calcareous swamps 4. *R. CAPILLACEA*
- a. Leaf-blades 0.5–20 mm. wide; leaf-blades flat; plants not of limestone ledges or calcareous swamps b
- b. Leaf-blades 3.5–20 mm. wide; spikelets (in flower) 10–15 mm. long (in fruit) 15–30 mm. long; achenes 4.4–6 mm. long; crown-like tubercle 14–23 mm. long, longer than the scales c
- c. Bristles 11–14 mm. long, much longer than achenes, 6; inflorescence with stiff ascending branches 1. *R. MACROSTACHYA*
- c. Bristles 2–4 mm. long, much shorter than achenes, usually 5 with some of them minute or scarcely evident; inflorescence with wide-spreading branches 2. *R. CORNICULATA*
- b. Leaf-blades 0.5–4 mm. wide; spikelets (in flower and fruit) 2–7 mm. (rarely 10) long; achenes 0.9–3 mm. (rarely 4) long; crown-like tubercle 0.2–2.6 mm. long, mostly shorter than or concealed by the scales d
- d. Spikelets much longer (4–5 times) than broad, narrowly elliptical or lance-elliptical; bristles conspicuous, equaling or nearly equaling combined length of achene and tubercle; tubercle about as long as body of achene, long triangular; surface of achenes smooth; teeth or barbs of the bristles pointing downward (retroarsely), or, if rarely pointing upward or smooth, then with smooth achenes and other characters referred to here 3. *R. CAPITELLATA*
- d. Spikelets only slightly longer than ($1\frac{1}{2}$ –2 times) broad, broadly ovoid to nearly globe-shaped; bristles weak or absent, much shorter than body of achene; tubercle $\frac{1}{3}$ – $\frac{1}{6}$ as long as body of achene, low conical or broadly triangular; surface of achenes not smooth, but either minutely honeycombed or with wavy transverse (horizontal) ridges between narrow cells of spaces; teeth or barbs of the bristles pointing upward (antrorsely) e
- e. Surface of achene minutely honeycombed with cells of about the same diameter, without wavy transverse ridges; tubercle $\frac{1}{4}$ – $\frac{1}{6}$ as long as body of achene, depressed conical; midrib of at least the lower scales of spikelets (do not confuse with lowermost bracts) conspicuously projecting into a tip 0.5–1 mm. long 5. *R. HARVEYI*
- e. Surface of achene with transverse (horizontal) wavy ridges between series of narrow cells or spaces longer than broad; tubercle about $\frac{1}{3}$ as long as body of achene, broadly triangular; midrib of the scales of the spikelet (do not confuse with lowermost bracts) scarcely or not at all projecting beyond tip of scale 6. *R. GLOBULARIS* var. *RECOGNITA*

1. *Rhynchospora macrostachya* Torr. var.
macrostachya Horned Rush Map 430
Flowers July–October.

Occurs in low swampy woods, around margins of sink-hole ponds, and along small streams in upland prairies. Found in the southern part of the state, principally in the southeastern lowland section and

around upland swamps and sink-hole ponds in Oregon and Howell counties, locally west to moist ground in an upland prairie in Barton County, southwestern Missouri (wet margins of small brook, upland prairie, 3 mi. east of Lamar, September 6, 1950, *Palmer 50932*).

Ranges from Florida to Texas, north to Maine, New York, Indiana, Michigan, Missouri, and Kansas.

1

2

3

4

5

6

433 *Rhynchospora capillacea*434 *Rhynchospora Harveyi*435 *Rhynchospora globularis* var. *recognita*

2. ***Rhynchospora corniculata*** (Lam.) Gray
var. ***corniculata*** Horned Rush Map 431
Rhynchospora corniculata (Lam.) [Gray [G, BB, P & S]
Flowers June–September.

Occurs in swamps, low wet woods, along ditches, drainage canals, and spring branches. Mostly in southeastern Missouri, where it is a characteristic plant of the southeastern lowland section, northward in eastern Missouri locally in St. Louis and Audrain counties, and at a single location in southwestern Missouri in Christian County (wet sandy margins of spring branch, 2 mi. southwest of Billings, July 13, 1955, *Palmer 60557*).

Ranges from Florida to Louisiana, north to Delaware, Kentucky, and Missouri.

Another variety, var. *interior* Fern., with achenes 4.4–5.3 mm. long and 2.4–2.8 mm. wide, instead of 5–6 mm. long and 2.8–3.3 mm. wide, ranges west to Texas and north to Arkansas and Indiana. A Missouri collection from Ripley County approaches the var. *interior*.

3. ***Rhynchospora capitellata*** (Michx.) Vahl f.
capitellata False Bog Rush Map 432
Flowers late May–October.

Occurs along rocky or sandy banks of streams and spring branches, and moist places in upland, or granite substrata. Found in the southern third of the state, north to Ste. Genevieve, St. Francois, Phelps, and Vernon counties.

Ranges from Florida to Texas, Oklahoma, and Missouri, north to Nova Scotia, Quebec, Ontario, and Wisconsin; also in California and Oregon.

Two forms which may be expected in Missouri, but so far have not appeared in collections in the state, are: *Rhynchospora capitellata* f. *controversa* (S. F. Blake) Gale, with the bristles upwardly toothed, and *R. capitellata* f. *discutiens* (C. B. Clarke) Gale, with the bristles smooth. The usual form encountered in Missouri with the downwardly toothed bristles is *R. capitellata* f. *capitellata*.

4. ***Rhynchospora capillacea*** Torr. Map 433
Flowers early June–September.

Occurs in wet seepy ground of spring-fed calcareous meadows of small valleys or on moist limestone ledges and rocks by small streams. Restricted to the Ozark section, and primarily to the eastern part of the Ozarks north to Jefferson and Miller counties, west to Laclede, Douglas, and Ozark counties.

Ranges from Newfoundland to Saskatchewan, south to New Jersey, Pennsylvania, Virginia, Tennessee, Ohio, Indiana, Illinois, Missouri, and South Dakota.

In Missouri *R. capillacea* is at its southwesternmost limit of range, where it represents a survivor from a time during the Ice Age (Pleistocene) when more northerly-distributed species pushed southward in the wake of the ice sheets and then remained stranded in their present relatively warmer sites following the retreat of the glaciers.

This fine-leaved *Rhynchospora* with delicate slender culms is a characteristic sedge of calcareous swampy meadows of the eastern Ozarks, occurring with other narrow-leaved sedges, such as *Carex interior*, *C. leptalea*, and *Scleria verticillata*.

5. ***Rhynchospora Harveyi*** Boott Map 434
Flowers June–July.

Occurs in sandstone glades and in swales of upland prairies, where it is known only from the unglaciated prairie section of southwestern Missouri, from St. Clair (ferruginous sandstone glade south of Birdsong, July 13, 1934, *Steyermark 13416*) and Newton (swales in upland prairie, 4 mi. northwest of Diamond, June 17, 1957, *Palmer 65631*) counties.

Ranges from Florida to Texas, north to Virginia, Tennessee, Missouri, and Oklahoma.

The stations in Missouri represent the most northwesterly known ones in the range of the species. *Rhynchospora Harveyi*, *R. capitellata*, and *R. globularis* var. *recognita* occur, in most cases, in soils of an acid reaction.

6. **Rhynchospora globularis** (Chapm.) Small var.
recognita Gale Map 435
Rhynchospora cymosa [of P & S], not Ell.
Flowers late May–October.

Occurs in wet or dry places in upland sandy prairies and meadows, and wet rocky banks. Restricted to the southern third of the state, north to Ste. Genevieve, Shannon, Polk, and Vernon counties, but commonest in the unglaciated prairie region in the southwestern section.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Maryland, North Carolina, Tennessee, Ohio, Illinois, Missouri, and Oklahoma.

Sometimes plants of this species may have the flowers infected by a smut, which produces a peculiar condensed appearance of the inflorescence, with only the scales of the spikelets remaining, and the rest of the flowers modified into smut spores. Such a specimen is *Palmer 65881* from Burkhart Prairie in Newton County.

This and other related species of the genus are apparently not browsed by cattle, as the margins and tips of the leaves possess microscopic teeth of silica which renders the leaves unfit for fodder (Gale in Rh. 46: 97. 1944).

10. **Scleria** Bergius Nut Rush

Annual or perennial plants with 3-cornered leafy culms (stems). Flowers few, the lower scales empty. Stamens 1–3. Style 3-cleft. Achene bony or enamel-like in hardness, the base surrounded by a simple, scalloped, or lobed disk (hypogynium) or ornamented with rounded or knob-like portions (tubercles).

- a. Main body of achene smooth *b*
- b. At the base of the achene are 8–9 small rounded tubercles; leaves thin; rootstock soft . . . 3. *S. OLIGANTHA*
- b. The base of the achene does not have 8–9 rounded tubercles but is set in a spongy ring whose surface is covered by minute pebble- or papillae-like grains; leaves hard and firm; rootstock hard, somewhat woody in texture *c*
- c. Surface of the ventral part of leaf-sheath (the side opposite the one that ends in the leaf-blade) covered with a fine dense hairiness, and scarcely contrasted in color with the ligule (thickened summit or appendage in which the ventral sheath ends); achene 2.8–3.3 mm. high, gradually rounded at the tip 2. *S. NITIDA*
- c. Surface of the ventral part of leaf-sheath glabrous or nearly glabrous (the margins of the sheath usually hairy), contrasting strongly in color with the darker ligule; achene 2–2.5 mm. high, strongly rounded at the tip 1. *S. TRIGLOMERATA*
- a. Main body of achene either warty, roughened with papillae, wrinkled, or honeycombed *d*
- d. Surface of achene with hairs in addition to the sculpturing and other ornamentation; lateral (those arising from the side) inflorescences on long, drooping, hair-like peduncles (stalk of inflorescence) 6. *S. MUHLENBERGII*
- d. Surface of achene without hairs, although other ornamentation is present; inflorescences not as above, either sessile (without stalks), or if stalked, the peduncles short and erect or ascending. *e*
- e. Clusters of spikelets 2–6 (rarely 1), sessile (stalkless) along an elongated interrupted axis; achene with transverse (horizontal) ridges or wrinkles; no rounded knobs (tubercles) at base of achene; annuals with delicate hair-like culms (stems) and soft leaves 7. *S. VERTICILLATA*
- e. Clusters of spikelets 1–3, close together at the top of the culm (stem), not spaced along an interrupted axis; achene warty or covered with granular or papillose projections; 3, 6, or 9 rounded knobs (tubercles) at base of achene; perennials with stiff or firm culms and hard or firm leaves *f*
- f. Rounded knobs (tubercles) at base of achene 3 (each of the 3 may be lobed into 2 parts); achene 2–3 mm. in diameter 5. *S. CILIATA*
- f. Rounded tubercles at base of achene 6 or 9; achene 1.5–2 mm. in diameter . . . 4. *S. PAUCIFLORA*

1. **Scleria triglomerata** Michx.
Tall Nut Grass Map 436
Flowers late May–September.
- Occurs on dry upland prairies, rocky glades, and rocky open woods. Throughout Missouri. This is the commonest species in the state, although unknown from more than half the counties of the state.

Ranges from Florida to Texas, north to Massachusetts, Vermont, New York, Ontario, Ohio, Michigan, Wisconsin, Minnesota, and Kansas.

The leaf-blades average the broadest (5–9 mm.) and the culms the thickest (2.5–6 mm. at base) of any of the species occurring in Missouri.

436 *Scleria triglomerata* (Tall Nut Grass)437 *Scleria nitida*438 *Scleria oligantha***2. *Scleria nitida* Willd.**

Map 437

Flowers May–October.

Occurs on sandy slopes along spring branches and on dry sandstone rock exposures. Known only from southeastern Missouri in Ste. Genevieve (dry exposed bluff tops, Pickle Springs, May 22, 1955, *Mohlenbrock 5244*) and Stoddard (sandy and mossy slopes above and along spring branch in valley at junction of Crowley Ridge and bottomland, on property of Mr. Martin, T₂₅N, R₁₁E, sect. 6, 3¼ mi. southeast of Bloomfield, October 17, 1955, *Steyermark 80375*) counties. The locality in Ste. Genevieve County is in the Ozark section of the state, while the Stoddard County station is in the Crowley Ridge section, in a unique botanical area (*Steyermark*, Rh. 60: 205–8, 1958) where the species is associated with such rarities as *Trisetum pensylvanicum*, *Paspalum setaceum*, *Bartonia paniculata*, *Pyrus melanocarpa*, and *Trichostema setaceum*.

Ranges from Florida to Louisiana, north to New Jersey, Kentucky, and Missouri.

The puberulent-tomentulose leaf-sheaths are sometimes dull purple throughout.

3. *Scleria oligantha* Michx.

Map 438

Flowers May–July.

Occurs in rocky, often cherty, open woods and glades, where restricted to the southernmost section of the Ozarks, extending east to Carter and Ripley counties and west to Barry County.

Ranges from Guatemala and Honduras in Central America to Mexico, Florida to Texas, north to Virginia, Kentucky, Indiana, and Missouri.

4. *Scleria pauciflora* Muhl.

Map 439

Flowers May–September.

Occurs in acid soils of sandstone, chert, or granite of glades and barrens, open woodland, edges of bluffs,

and upland prairies. Restricted to the Ozark section of southern and east-central Missouri southeast of a line extending from Lincoln, Montgomery, Maries, Camden, Hickory, and St. Clair counties to Vernon County, but absent from the southeastern lowland section of the state.

Missouri material may be divided into two varieties:

Culms (stems) glabrous or scarcely hairy; leaves glabrous or sparsely short-hairy . 4a. *S. PAUCIFLORA*

var. *PAUCIFLORA*

Culms conspicuously hairy; leaves conspicuously hairy, the hairs often 1 mm. long . 4b. *S. PAUCIFLORA*

var. *CAROLINIANA***4a. *Scleria pauciflora* var. *pauciflora* Map 439**

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Kentucky, Missouri, and Kansas.

4b. *Scleria pauciflora* var. *caroliniana* (Willd.)

Wood

Map 439

Ranges from Florida to Tennessee and Missouri, north to New Hampshire, New York, Ohio, and Michigan.

5. *Scleria ciliata* Michx.

Map 440

Flowers June–October.

Occurs in acid soils of sandstone, chert, or granite substrata in openings of glades or rocky open woods and on upland sandy prairies.

Missouri material may be divided into the following two varieties:

Leaf-blades 1–2.5 mm. wide, soon turning back the margins (revolute); culms glabrous or slightly hairy; margins of bracts of inflorescence with short hairs; scales of spikelets glabrous or nearly so 5a. *S. CILIATA* var. *CILIATA*

Leaf-blades 3–7 mm. wide, mostly remaining flat;

PLATE NO. 83

culms hairy; margins of bracts of inflorescence conspicuously long-hairy; scales of spikelets hairy. . . . 5b. *S. CILIATA* var. *ELLIOTTII*

5a. ***Scleria ciliata* var. *ciliata*** Map 440
Scleria ciliata Michx. [G, BB, P & S in part]

Known only from southwestern Missouri in Taney (rocky woods, Swan, September 27, 1905, *Bush* 3473) and McDonald (rocky open woods, 1½ mi. SE of Pineville, August 15, 1957, *Palmer* 66253) counties. Both these collections represent the more glabrate extremes of Missouri collections and are therefore referred to the var. *ciliata*.

Ranges from Florida to Texas, north to Virginia and Missouri.

5b. ***Scleria ciliata* var. *Elliottii*** (Britt.) Fern.

Map 440

Scleria Elliottii Britton [as synonym of *S. ciliata* var. *ciliata* in P & S]

This is the commoner variety in Missouri, with more pubescent culms, bracts, and scales, and wider leaves. However, transitional types which have the narrower leaf-blades of var. *ciliata* and the pubescent culms of var. *Elliottii* are frequent.

Ranges from Florida to Texas, north to Virginia, Missouri, and Oklahoma.

Achenes are often gray or of a smoky color.

6. ***Scleria Muhlenbergii*** Steud. Map 441

Scleria setacea [of P & S], not Poir.

Scleria reticularis var. *pubescens* Britt. [BB]

Flowers August–October.

Known only from Greene County, southwestern Missouri (wet ground, August 16, 1892, *Bush*).

Ranges from Florida to Texas, north to New York, New Jersey, Pennsylvania, Tennessee, Indiana, and Missouri; also in the West Indies, Mexico, and Central America.

This species has not been re-collected since Bush's original collection.

7. ***Scleria verticillata*** Muhl. Map 442
Flowers July–September.

Occurs in spring-fed calcareous swampy meadows and in moist seepage at base of limestone bluffs. Rare and local in the Ozark region, where known from Jefferson, Reynolds, Camden, and McDonald counties.

Ranges from Connecticut and Ontario to Minnesota, south to Florida and Texas, Mexico, the West Indies, Central and South America.

The leaves of this species, 0.5–2 mm. wide, average narrower than any of the other species in Missouri.

In the calcareous swampy meadows which this species inhabits, it is associated with other calciphiles, such as *Rhynchospora capillacea*, *Juncus subcaudatus*, *Parnassia grandifolia*, *Pedicularis lanceolata*, *Selaginella apoda*, *Solidago patula*, and *Aster puniceus* var. *firmus* f. *lucidulus*.

It is probable that the species will be eventually found at many more stations throughout the Ozarks.

11. *Carex* L. Sedge

Perennial plants with usually narrow leaves. Flowers either staminate (male) or pistillate (female), in short head-like or long, slender spikes, with the staminate and pistillate flowers occurring on the same plant in different parts of the same spike, or in separate spikes on the same culm (stem), or rarely on separate plants (dioecious). At the base of the spike is a bract, which is leaf-like and may or may not have a sheath, or is not leaf-like and reduced to a sheath only. Sometimes these spikes appear (a) all *alike* with the staminate flowers at the base of the spike and the pistillate flowers at the top of the same spike (gynecandrous), or with the staminate flowers at the top of the spike and the pistillate flowers at the base of the same spike (androgynous), or the sexes scattered in different parts of the same spike; or sometimes these spikes are (b) all pistillate, or all or part staminate. Each staminate or pistillate flower is in the axil of a scale. The staminate flowers consist of 3 stamens. The pistillate flower consists of 1 pistil with a style of 2 or 3 stigmas enclosed by a loose or tightly-fitting green, yellow, or brown sac (perigynium). The ovary (turning into the mature achene) within the perigynium is either 2-sided (lenticular) or 3-sided (trigonus). Sometimes the achene is nearly rounded.

There are always those who attempt to evaluate all living objects in relation to mankind, and require some explanation as to the possible use or economic value concerned. In the present case of *Carex*, with such an abundance of species and individual plants comprising the flora, it is perhaps surprising that the group as a whole has little or no economic importance. However, the important ecological role performed by the various species is a great one, often overlooked by those who are not satisfied unless they have some immediate explanation for the usefulness of the carices. In Deam's *Flora of Indiana* the thought about the importance of this group is well expressed by the following statement taken from that work (p. 212): 'The species of marshes and muddy borders of lakes which form extensive colonies, and to some extent the less gregarious species, comprise an essential step in the successional stages from open water to the culmination in climax forest or prairie. Much of the fertile soils of our region today would still be barren mudflats were it not for the part played by these sedges in the conversion of the once great boggy areas into a turf, thus enabling less hydrophytic plants to become established and add further to the fertility of the soil.' Furthermore, the achenes of the plants are eaten by various birds, while the leaves are often grazed upon by deer, rabbits, and other wild animals, as well as by cattle. Some species with their large tussocks or mounds of leaves offer nesting sites for some kinds of ground birds, protective cover for certain small birds and fur-bearing animals, and insect habitats. Marsh hay from the northern and eastern states, used for winter mulches and bedding purposes for wintering animals, often includes species of *Carex*. The tough and long leaves of some species may be used for tying loose objects temporarily together.

In order to be certain of one's identification in this group, the largest genus encountered in Missouri, it is necessary to have fully mature pistillate flowers with well developed achenes, and a complete specimen with roots and all. There follow three separate categories which may be used in identification: (1) a summarized listing of species into various groups offered more as a guide which may be useful in the field or for bypassing more technical characters; (2) a key to the sections of the genus in Missouri; and (3) a key to species of the genus.

Category 1.

It may prove of some help and advantage in enabling one to identify various species of *Carex* in the field or to simplify some of the steps in identification by utilizing certain obvious characters to be found associated with a particular habitat, habit, or with easily observable gross features of the plant. With a view towards making available such information for this purpose, the following leads or groupings are offered (species are arranged alphabetically within each grouping):

1. *Leaves glaucous or silvery green* (either slightly or greatly)
Carex albursina, *C. blanda*, *C. Crawei*, *C. crus-corvi*, *C. flaccosperma* var. *flaccosperma*, *C. flaccosperma* var. *glaucodea*, *C. granularis*, *C. hyalinolepis*, *C. Joori*, *C. laxiculmis*, *C. Meadii*.
2. *Leaves (leaf-sheaths or blades) and/or culms hairy*
Carex atherodes, *C. Bushii*, *C. caroliniana*, *C. complanata* var. *complanata*, *C. complanata* var. *hirsuta*, *C. Davisii*,

- C. debilis* (leaf-blades merely scabrous-hirtellous), *C. hirtifolia*, *C. Hitchcockiana* (leaf-sheaths only), *C. oxylepis*, *C. Swanii*, *C. virescens*.
3. *Perigynia hairy*
Carex abdita, *C. artitecta*, *C. communis*, *C. Grayii* var. *hispidula*, *C. hirtifolia*, *C. lanuginosa*, *C. nigromarginata*, *C. pensylvanica*, *C. physorhyncha*, *C. × subimpressa*, *C. Swanii*, *C. trichocarpa*, *C. umbellata*, *C. virescens*.
 4. *Perigynia white or gray-white*
Carex Buxbaumii, *C. communis*, *C. Meadii*, *C. nigromarginata*, *C. pensylvanica*.
 5. *Plants forming large colonies or beds*
Carex Buxbaumii, *C. Emoryi*, *E. Haydenii*, *C. hyalinolepis*, *C. lacustris*, *C. laevisconica*, *C. lanuginosa*, *C. × subimpressa*, *C. trichocarpa*, *C. vesicaria* var. *monile*.
 6. *Pistillate spikes nodding, curving, or loosely spreading (at least some of them)*
Carex cherokeensis, *C. comosa*, *C. crinita*, *C. Davisii*, *C. debilis*, *C. digitalis*, *C. gracillima*, *C. Joori*, *C. hystericina*, *C. laxiculmis*, *C. lurida*, *C. oxylepis*, *C. torta*.
 7. *Pistillate flowers 1-9 in a spike*
Carex abdita, *C. amphibola* var. *amphibola*, *C. amphibola* var. *globosa*, *C. amphibola* var. *rigida* (or more), *C. amphibola* var. *turgida* (or more), *C. blanda*, *C. Careyana*, *C. communis*, *C. convoluta*, *C. digitalis*, *C. eburnea*, *C. flaccosperma* (or more), *C. gracilescens*, *C. Hitchcockiana*, *C. interior*, *C. intumescens* (or more), *C. Jamesii*, *C. laxiculmis*, *C. leptalea* (or more), *C. nigromarginata*, *C. oligocarpa*, *C. pensylvanica*, *C. physorhyncha*, *C. retroflexa*, *C. rosea*, *C. texensis*, *C. tonsa*, *C. umbellata*.
 8. *Pistillate spikes or mixed spikes globose or nearly so or as broad as or broader than long*
Carex abdita, *C. albolutescens*, *C. arkansana*, *C. artitecta*, *C. Bicknellii*, *C. brevior*, *C. Bushii*, *C. caroliniana*, *C. cephalophora*, *C. communis*, *C. complanata*, *C. convoluta*, *C. cristatella*, *C. eburnea*, *C. Grayii*, *C. interior*, *C. intumescens*, *C. Jamesii*, *C. Leavenworthii*, *C. mesochorea*, *C. molesta*, *C. Muhlenbergii*, *C. nigromarginata*, *C. normalis*, *C. pensylvanica*, *C. physorhyncha*, *C. projecta*, *C. retroflexa*, *C. rosea*, *C. Sartwellii*, *C. sparganioides*, *C. straminea*, *C. Swanii*, *C. tenera*, *C. texensis*, *C. tonsa*, *C. umbellata*.
 9. *Plants of limestone glades*
Carex austrina, *C. Crauei*, *C. granularis* var. *Haleana* (or other habitats), *C. Meadii*, *C. microdonta*.
 10. *Plants of crevices of limestone bluffs*
Carex eburnea, *C. granularis* var. *Haleana*.
 11. *Plants of upland natural sink-hole ponds of the Ozarks (* exclusively)*
*Carex alata**, *C. annectens*, *C. comosa*, *C. crinita*, *C. × Deamii*, *C. decomposita**, *C. hyalinolepis*, *C. lupulina*, *C. scoparia*, *C. Shortiana*, *C. stipata*, *C. straminea**, *C. tribuloides*.
 12. *Plants of calcareous spring-fed swampy meadows of the Ozarks (* exclusively or nearly so)*
Carex annectens var. *xanthocarpa*, *C. Buxbaumii*, *C. crinita*, *C. cristatella*, *C. Frankii*, *C. granularis*, *C. hystericina*, *C. interior**, *C. lanuginosa*, *C. leptalea**, *C. lurida*, *C. Shortiana*, *C. squarrosa*, *C. stricta**, *C. suberecta**, *C. trichocarpa**, *C. vulpinoidea*.
 13. *Plants in the water of or along the banks of small or large streams (* characteristic or mostly)*
Carex aggregata, *C. amphibola*, *C. aquatilis* var. *altior*, *C. blanda*, *C. conjuncta*, *C. crinita*, *C. Davisii*, *C. Emoryi**, *C. Frankii*, *C. granularis*, *C. Haydenii*, *C. Leavenworthii*, *C. laevisconica*, *C. leptalea*, *C. lurida*, *C. normalis*, *C. oklahomensis*, *C. squarrosa*, *C. stipata*, *C. torta**, *C. tribuloides*, *C. vulpinoidea*.
 14. *Plants of north-facing wooded limestone slopes*
Carex albursina, *C. amphibola*, *C. blanda*, *C. Careyana*, *C. cephalophora*, *C. communis*, *C. convoluta*, *C. digitalis*, *C. Hitchcockiana*, *C. Jamesii*, *C. laxiculmis*, *C. oligocarpa*, *C. sparganioides*.
 15. *Plants characteristic of rich woods not subject to flooding (on or at the base of slopes, ravines, and wooded valleys)*
Carex aggregata, *C. amphibola*, *C. blanda*, *C. Careyana*, *C. conjuncta*, *C. convoluta*, *C. Davisii*, *C. digitalis*, *C. gracilescens*, *C. grvida* var. *Lunelliana*, *C. hirtifolia*, *C. Hitchcockiana*, *C. Jamesii*, *C. laxiculmis*, *C. normalis*, *C. oligocarpa*, *C. oxylepis*, *C. Muhlenbergii*, *C. retroflexa*, *C. rosea*, *C. Shortiana*, *C. sparganioides*, *C. typhina*, *C. virescens*.

16. *Plants of dry acid soils in woodland* (either open woods on upland, along sandstone ledges, sandstone bluffs, or cherty or granite slopes)
Carex abdita, *C. arkansana*, *C. artitecta*, *C. austrina*, *C. cephalophora*, *C. complanata*, *C. digitalis*, *C. flaccosperma* var. *glaucoidea*, *C. gracilescens*, *C. Muhlenbergii*, *C. nigromarginata*, *C. oxylepis*, *C. pensylvanica*, *C. retroflexa*, *C. tonsa*, *C. virescens*.
17. *Base of plant with purple-red or wine-red or maroon-magenta coloring*
Carex amphibola var. *amphibola*, *C. aquatilis* var. *altior*, *C. artitecta*, *C. Bushii*, *C. Buxbaumii*, *C. Careyana*, *C. caroliniana*, *C. communis*, *C. complanata*, *C. conoidea* (often), *C. convoluta* (sometimes), *C. crinita* (frequently), *C. Davisii*, *C. debilis*, *C. Emoryi*, *C. Frankii*, *C. gigantea*, *C. gracillima*, *C. gracilescens* (sometimes to often), *C. Grayii*, *C. Haydenii*, *C. hirtifolia*, *C. Hitchcockiana*, *C. hystericina*, *C. intumescens*, *C. lacustris*, *C. laeviconica*, *C. lanuginosa*, *C. louisianica*, *C. lupuliformis*, *C. lupulina* (sometimes), *C. lurida*, *C. nigromarginata*, *C. oligocarpa*, *C. oxylepis*, *C. pensylvanica*, *C. physorhyncha*, *C. Schweinitzii*, *C. Shortiana*, *C. stricta* var. *strictior*, *C. × subimpressa*, *C. Swanii*, *C. tetanica*, *C. texensis* (sometimes), *C. tonsa*, *C. torta*, *C. trichocarpa*, *C. typhina* (sometimes), *C. umbellata*, *C. virescens*, *C. Woodii*.
18. *Leaf-blades mostly between 0.5–3.5 mm. wide* (leaf-blades which vary to 4.5 mm. wide are not included)
Carex abdita, *C. albulutescens*, *C. amphibola* var. *amphibola*, *C. arkansana*, *C. artitecta*, *C. brevior*, *C. Buxbaumii*, *C. complanata*, *C. convoluta*, *C. Crawei*, *C. Douglasii*, *C. eburnea*, *C. festucacea*, *C. interior*, *C. Jamesii*, *C. Leavenworthii*, *C. leptalea*, *C. molestia*, *C. nigromarginata*, *C. pensylvanica*, *C. physorhyncha*, *C. praegracilis*, *C. retroflexa*, *C. rosea*, *C. scoparia*, *C. straminea*, *C. suberecta*, *C. Swanii*, *C. tenera*, *C. texensis*, *C. tonsa*, *C. umbellata*, *C. virescens*, *C. Woodii*.
19. *Leaf-blades averaging 10–30 mm. or more wide* (and with blades never less than 7 mm. wide)
Carex albusina, *C. Careyana*, *C. lupuliformis*, *C. stipata* var. *maxima*.

Category 2.

For those who wish to key their plants to sections, the following key, based upon the monograph of *Carex* by Mackenzie (*North American Flora* 18: 1–478), and the treatments of Fernald in *Gray's Manual*, eighth edition, of Kükenthal in *Das Pflanzenreich* IV. 20. 1909, and of Hermann in *Deam's Flora of Indiana*, is offered.

Key to the Sections of Missouri Carices

Stigmas 2; achenes lenticular (2-sided); spikes usually with both staminate and pistillate flowers (bisexual), the lateral spikelets sessile Subgenus I. VIGNEA

Stigmas 3; achenes more or less 3-sided or triangular, or if stigmas 2 and achenes 2-sided, then the lateral spikes peduncled (stalked); spikes mostly either staminate or pistillate (unisexual) . . . Subgenus II. EUCAREX

Subgenus I. Vignea

- a. Terminal or all spikes androgynous (staminate flowers at apex) b
- b. Culms from long-creeping rootstocks, mostly arising singly or few together c
- c. Beak of perigynium 1/2–5/8 as long as main body of perigynium; upper leaf-sheaths hyaline (transparent) or brown, not finely striate (lined) on the ventral (inner) side . . . 1. DIVISAE (p. 330, C. PRAEGRACILIS, C. DOUGLASII)
- c. Beak of perigynium 1/4–1/3 as long as main body of perigynium; upper leaf-sheaths green and finely striate on the ventral side 2. INTERMEDIAR (p. 330, C. SARTWELLII)
- b. Culms caespitose with the leafy shoots and culms rather crowded or close together, the rootstocks not long-creeping d
- d. Spikes generally 10 or fewer (up to 15), in mostly simple close or interrupted heads, often greenish . . . 3. BRACTEOSAE (p. 330, C. RETROFLEXA, C. CONVOLUTA, C. ROSEA, C. CEPHALOPHORA, C. LEAVENWORTHII, C. ARKANSANA, C. MUHLENBERGII, C. GRAVIDA, C. AGGREGATA, C. SPARGANIOIDES)
- d. Spikes numerous, in panicle spike-like heads, at least the lowest lateral branches of the spike bearing 2 or more spikes e
- e. Leaf-sheaths tightly enveloping the culm (stem); culms firm and more or less slender; perigynia firm or rigid, flattened or convex on the inner (upper) face, rather closely surrounding the achene, 1.7–4 mm. long f

- f. Perigynia flat on inner face, convex on outer face, thin, yellow, buff, or greenish; inner (ventral) side of leaf-sheath usually roughened or wrinkled transversely; pistillate scales awned; at least the lower bracts of the inflorescence prolonged and setaceous or leaf-like 4. MULTIFLORAE (p. 335, *C. VULPINOIDEA*, *C. ANNECTENS*, *C. TRIANGULARIS*)
- f. Perigynia more or less convex on each side, thick and inflated; inner side of leaf-sheath not transversely roughened or wrinkled; pistillate scales acute to shortly mucronate-tipped; bracts of inflorescence not present or very short 5. PANICULATAE (p. 336, *C. DECOMPOSITA*)
- e. Leaf-sheaths loose around the culm; culms soft, becoming flattened when pressed; perigynia soft and thin, with a soft spongy or corky base, more or less inflated and loosely surrounding the achene, 4-9 mm. long 6. VULPINAE (p. 338, *C. OKLAHOMENSIS*, *C. STIPATA*, *C. LAEVIVAGINATA*, *C. CRUS-CORVI*, *C. CONJUNCTA*)
- a. Terminal or all spikes gynecandrous (upper flowers pistillate, lower staminate) or the staminate flowers scattered in the spike g
- g. Perigynia without winged borders, at most only with thin edges; perigynia thickened or spongy at base 7. STELLULATAE (p. 340, *C. INTERIOR*)
- g. Perigynia with winged borders; perigynia not thickened nor spongy at base 8. OVALES (p. 340, *C. MUSKINGUMENSIS*, *C. SCOPARIA*, *C. TRIBULOIDES*, *C. PROJECTA*, *C. CRISTATELLA*, *C. NORMALIS*, *C. TENERA*, *C. FESTUCACEA*, *C. ALBOLUTESCENS*, *C. SUBERECTA*, *C. BREVIOR*, *C. MOLESTA*, *C. BICKNELLII*, *C. ALATA*, *C. STRAMINEA*)

Subgenus II. *Eu-Carex*

- a. Style articulated (jointed) with the achene, deciduous (falling) in age from the mature achene b
- b. Spike solitary, terminal, androgynous (staminate flowers at apex); perigynia without a beak, rounded at the summit, glabrous 9. POLYTRICHOIDEAE (p. 346, *C. LEPTALEA*)
- b. Spikes 2 or more, the perigynia not as above c
- c. Lower pistillate scales prolonged, leaf- or bract-like; staminate scales with margins united at base, tightly clasping the axis (rachis) 10. PHYLLOSTACHYAE (p. 346, *C. JAMESII*)
- c. Lower pistillate scales not prolonged or leaf- or bract-like; staminate scales loosely ascending, the margins free and not united at base d
- d. Achenes with rounded or convex sides, closely surrounded by the perigynium; lowest bract of inflorescence scale- or bristle-like, without any sheath 11. MONTANAE (p. 347, *C. ARTITECTA*, *C. NIGROMARGINATA*, *C. PHYSORHYNCHA*, *C. PENNSYLVANICA*, *C. COMMUNIS*, *C. UMBELLATA*, *C. ABDITA*, *C. TONSA*)
- d. Achenes with flat or concave sides; lowest bract of inflorescence with or without a sheath e
- e. Perigynia closely surrounding the achene, tightly filled to the summit by the achene; bracts, when present, with definite sheaths f
- f. Perigynia glabrous; leaves and culms glabrous 12. ALBAE (p. 350, *C. EBURNEA*)
- f. Perigynia pubescent; leaves and culms pubescent 13. TRIQUETRAE (p. 351, *C. HIRTIFOLIA*)
- e. Perigynia not closely surrounding the achene, the summit usually empty and not filled by the achene; bracts with or without sheaths g
- g. Styles 2; achenes lenticular h
- h. At least the lower pistillate scales with long rough awns mostly 2-4 times longer than perigynia (sometimes only slightly longer); pistillate spikes mostly all peduncled (stalked), usually nodding or arching 28. CRYPTOCARPAE (p. 372, *C. GRINITA*)
- h. Pistillate scales obtuse to acute, rarely with a short awn, shorter than or somewhat longer than the perigynia; pistillate spikes usually sessile (without stalks), rarely on long peduncles, erect to arching or nodding 27. ACUTAE (p. 368, *C. AQUATILIS* var. *ALTIOR*, *C. NEBRASKENSIS*, *C. HAYDENII*, *C. EMORYI*, *C. STRICTA*, *C. TORTA*)
- g. Styles 3; achenes 3-sided (trigonus) i
- i. Bract at base of inflorescence without a sheath or scarcely with a sheath (if the sheath prolonged, then the perigynia are plump, pubescent, and with a 2-toothed beak) j
- j. Leaves and perigynia glabrous (perigynia minutely scabrous in some species) k
- k. Perigynia without any beak or with a toothless or slightly 2-toothed short-beaked tip l
- l. Perigynia closely appressed-ascending, flattened, 1-2 mm. broad 26. ATRATAE (p. 366, *C. BUXBAUMII*)

1. Perigynia squarrose (tips turning outward from the center) or spreading, plump or with bulging sides, 1.7–3.5 mm. thick *m*
- m. Terminal spike completely staminate; perigynia longer than broad, strongly nerved, 4–5 mm. long 25. PENDULINAE (p. 366, C. JOORI)
- m. Terminal spike pistillate except at base; perigynia as broad as long, without nerves, 2.5–3 mm. long 24. SHORTIANAE (p. 366, C. SHORTIANA, C. × DEAMII)
- k. Perigynia with a definite beak, minutely scabrous 23. ANOMALAE (p. 366, C. SCABRATA)
- j. Leaves or perigynia or both pubescent *n*
- n. Beak of perigynium without teeth at summit or at most the summit barely notched; leaf-sheaths or blades or both more or less pubescent; plants with long creeping rootstocks
 21. VIRESCENTES (p. 363, C. VIRESCENS, C. SWANII, C. COMPLANATA, C. CAROLINIANA, C. BUSHII)
- n. Beak of perigynium definitely 2-toothed at summit; leaves glabrous; plants cespitose, without creeping rootstocks 22. HIRTAE (p. 364, C. LANUGINOSA)
- i. Bract at base of inflorescence with a prolonged closed sheath; perigynia always glabrous *o*
- o. Terminal spike mostly pistillate except at base where staminate 18. GRACILLIMAE (p. 360, C. GRACILLIMA, C. OXYLEPIS, C. DAVISII)
- o. Terminal spike usually completely staminate *p*
- p. Pistillate spikes short, oblong or linear, erect, or if drooping, the perigynia sharply 3-sided *q*
- q. Perigynia with few to many strongly raised nerves *r*
- r. Perigynia tapering at base, triangular; perigynia closely surrounding and tight about the achenes *s*
- s. Plants with creeping rootstocks and small tufts of leaves; perigynia glaucous or gray-green 14. PANICEAE (p. 351, C. MEADII, C. TETANICA, C. WOODII)
- s. Plants without creeping rootstocks; leaves prominently developed; perigynia green or olive-green 15. LAXIFLORAE (p. 352, C. CAREYANA, C. DIGITALIS, C. LAXICULMIS, C. ALBURSINA, C. BLANDA, C. GRACILESCENS)
- r. Perigynia rounded at the base, somewhat rounded in cross-section; perigynia loosely surrounding the achenes 16. GRANULARES (p. 355, C. GRANULARIS, C. CRAWELI, C. MICRODONTA)
- q. Perigynia with many fine impressed nerves 17. OLIGOCARPAE (p. 356, C. OLIGOCARPA, C. HITCHCOCKIANA, C. CONOIDEA, C. AMPHIBOLA, C. FLACCOSPERMA)
- p. Pistillate spikes elongate, linear to cylindric, on slender peduncles (stalks), at least the lower drooping, nodding, or spreading *t*
- t. Base of plant purple or reddish-purple; no green leaf-blades produced from the lower sheaths at the base of the culm; pistillate spikes narrowly linear, 3–4 mm. wide 19. SYLVATICAE (p. 362, C. DEBILIS)
- t. Base of the plant strongly marked with brown; well-developed green leaf-blades produced from the lower sheaths at the base of the culm; pistillate spikes oblong-cylindric, 5–10 mm. wide 20. LONGIROSTRES (p. 363, C. CHEROKEENSIS)
- a. Style not articulated but continuous with the achene, persistent to the summit of the achene. *u*
- u. Perigynia broadest in the upper half, obovoid or obconic, abruptly contracted and rounded above to a beak 31. SQUARROSAE (p. 378, C. FRANKII, C. SQUARROSA, C. TYPHINA)
- u. Perigynia broadest between the base and the middle, gradually tapering to the beak *v*
- v. Perigynia at maturity subcoriaceous, of firm or thick texture, scarcely inflated; perigynia glabrous or pubescent; leaf-blades and sheaths glabrous or pubescent 30. PALUDOSAE (p. 374, C. LACUSTRIS, C. HYALINOLEPIS, C. × SUBIMPRESSA, C. ATHERODES, C. LAEVICONICA, C. TRICHOCARPA)
- v. Perigynia at maturity membranaceous, of thin or papery texture, usually conspicuously inflated; perigynia usually glabrous; leaf-blades and sheaths glabrous. *w*
- w. Pistillate scales with scabrous awns equaling or longer than the rest of the scale 29. PSEUDO-CYPHEREAE (p. 372, C. HYSTRICINA, C. COMOSA, C. LURIDA, C. SCHWEINITZII)
- w. Pistillate scales blunt or cuspidate, if awned the awn smooth and less than half as long as the rest of the scale *x*
- x. Staminate spike usually 1 (sometimes 2–5); perigynia 10–20 mm. long; achenes 2.5–6 mm. long, 2–4 mm. wide 33. LUPULINAE (p. 380, C. GRAYII, C. INTUMESCENS, C. LOUISIANICA, C. LUPULINA, C. LUPULIFORMIS, C. GIGANTEA)
- x. Staminate spikes usually 2–4 (in the Missouri species); perigynia 5–8 mm. long (in Missouri species); achenes 2–3 mm. long, 1.25–2.5 mm. wide. 32. VESICARIAE (p. 380, C. VESICARIA)

The following key to species attempts to utilize characters to be found in the foliage, flowers, and fruit, as well as in the habit and habitat of the plant:

Category 3.

Key to species

- a. Hairs present on some part of the surface of the leaves (leaf-sheaths or leaf-blades or both), bracts, or culms (stems) (sometimes the hairs are found on the lower leaf-sheaths only) (rough-margined scabrous leaves and culms are placed in the other *a.* section) *b*
- b. Perigynia hairy *c*
 - c. Perigynia 3.5–5 mm. long; topmost (terminal) flower spike of staminate (male) flowers only; leaf-blades 3–10 mm. wide 50. *C. HIRTIFOLIA*
 - c. Perigynia 1.8–2.5 mm. long; topmost (terminal) flower spike mostly of pistillate (female) flowers except at the base where staminate; leaf-blades 2–4 mm. wide *d*
 - d. Pistillate spikes linear, narrowed to the base, (11–) 15–40 mm. long, 4–8 times longer than broad; leaves usually shorter than the flowering culms 73. *C. VIRESCENS*
 - d. Pistillate spikes broadly oblong to oblong-globose, rounded or broadened at the base, mainly 4–15 mm. long, mainly $1\frac{1}{2}$ –4 times longer than broad; leaves usually longer than the flowering culms 74. *C. SWANII*
- b. Perigynia glabrous *e*
 - e. Topmost (terminal) flower spike of staminate (male) flowers only *f*
 - f. Styles 2; achenes 2-sided or 2-angled 87. *C. STRICTA* var. *STRICTIOR*
 - f. Styles 3; achenes 3-sided or 3-angled *g*
 - g. Plant forming large colonies with creeping rhizomes; mature perigynia 7–12 mm. long, ending in a conspicuous 2-pronged beak with teeth 1.6–3 mm. long; pistillate spikes 6–10 mm. wide 96. *C. ATHERODES*
 - g. Plants in single clumps or tufts; mature perigynia 4.5–7 mm. long, either without beaks or the beaks without conspicuous teeth; pistillate spikes 2–4 mm. wide *h*
 - h. Only 1–8 flowers in a pistillate (female) spike; plant brown at base (near soil); pistillate spikes erect, 8–25 mm. long; leaf-sheaths with hairs 64. *C. HITCHCOCKIANA*
 - h. Ten or more flowers in a pistillate spike; plant with purple or red-purple at base; pistillate spikes spreading or nodding, 28–60 mm. long; no hairs on leaf-sheaths 71. *C. DEBILIS*
- e. Topmost (terminal) flower spike with pistillate (female) flowers in the upper part and staminate (male) flowers at the base *i*
 - i. All spikes 18–45 mm. long, 6–8 times longer than broad, linear to narrowly oblong-cylindrical *j*
 - j. At least the upper scales of pistillate flowers usually with a long awn or narrowed tip about as long or half as long as the main part of the scale; spikes mainly 5–7 mm. thick; perigynia inflated and loose around the achene, oblong-ovoid, broadest in the lower half; common and throughout Missouri 70. *C. DAVISII*
 - j. At least the upper scales of pistillate flowers with a short point or tip much shorter than the main part of the scale; spikes 3–5 mm. thick; perigynia not inflated, close to the achene, narrowly ellipsoid and narrowed below the middle; rare, found only in the southeastern lowland section of Missouri 69. *C. OXYLEPIS*
 - i. All spikes, except the topmost (terminal) one, mainly 5–20 mm. long, $1\frac{1}{2}$ –4 times longer than broad, narrowly ovoid or short cylindric *k*
 - k. Scales of pistillate flowers 3–6 mm. long, with a prominent awn or projection from the tip and longer than the perigynium; perigynia 3–4 mm. long 77. *C. BUSHII*
 - k. Scales of pistillate flowers 2–3 mm. long, obtuse to short-pointed, and shorter than the perigynium; perigynia 2.2–3.5 mm. long *l*
 - l. Culms, leaf-sheaths, and leaf-blades conspicuously hairy 75b. *C. COMPLANATA* var. *HIRSUTA*
 - l. Culms, leaf-sheaths, and leaf-blades sparsely hairy to nearly or quite hairless *m*
 - m. Perigynia conspicuously nerved on both faces; perigynia spreading, plump, about equally rounded on outer and inner faces, nearly as thick as wide, short-pointed at the tip; achenes very abruptly bent at tip; common species 76. *C. CAROLINIANA*
 - m. Perigynia usually without nerves on the upper face, only weakly nerved on

the lower face; perigynia more appressed or closely ascending, somewhat flattened with the inner face flattish, much wider than thick, rounded at tip; achenes only slightly bent at tip; rare 75a. *C. COMPLANATA* var. *COMPLANATA*

- a. Hairs absent on leaves, bracts, and culms (rough or scabrous margins or surfaces are keyed out in this section) n
- n. Surface of perigynia hairy or with a minute rough puberulence (rough-toothed or serrulate beaks of glabrous perigynia are not included here) o
- o. Pistillate spikes 20-40 mm. thick, forming a ball- or globe-shape; perigynia 12-20 mm. long 103b. *C. GRAYII* var. *HISPIDULA*
- o. Pistillate spikes and perigynia smaller p
- p. Most or all of the flowering culms much shorter than and/or hidden by the leaf-blades (do not confuse leaf-like bracts of inflorescence with ordinary leaf-blades; on late-season plants, remains of old fruiting stalks [peduncles] may be found among the leaf-bases); flowering culms mostly 0.1-2 dm. tall q
- q. Only 1 peduncle (stalk supporting inflorescence) arising from each culm; most of peduncles conspicuous and elongated, 5-20 cm. long, mostly all similar and producing both staminate and pistillate flowers; rare species of southern and southeastern Missouri 42. *C. NIGROMARGINATA*
- q. 2 to 4 peduncles of different lengths arising from each culm; peduncles not alike, 1 elongated with staminate or staminate and pistillate flowers, the other 1-3 very short (1-5 cm. long) and pistillate only and hidden in the densely tufted bases, or rarely a few of the pistillate peduncles elongated (5-20 cm. long); common species r
- r. Beak of perigynium 0.9-1.7 mm. long, about 3/4 as long as the main body of perigynium; scales of pistillate flowers with usually long-pointed (acuminate) tips 46. *C. UMBELLATA*
- r. Beak of perigynium 0.5-1 mm. long, about 1/2 as long as the main body of perigynium; scales of pistillate flowers with usually short-pointed (acute) tips 47. *C. ABDITA*
- p. Without the above combination of characters; most or all of the flowering culms longer than and not hidden by the leaf-blades (do not confuse leaf-like bracts of inflorescence with ordinary leaf-blades); or culms 2-12 dm. tall s
- s. Topmost (terminal) flower spike with pistillate (female) flowers in the upper part and staminate (male) flowers at the base t
- t. Scales of pistillate flowers 3-6 mm. long, with a prominent awn or point projecting and longer than the perigynium; perigynia 3-4 mm. long 77. *C. BUSHII*
- t. Scales of pistillate flowers 2-3 mm. long, obtuse to short-pointed, and shorter than the perigynium; perigynia 2.2-3.5 mm. long u
- u. Perigynia conspicuously nerved on both faces; perigynia spreading, plump, about equally rounded on outer and inner faces, nearly as thick as wide; common species 76. *C. CAROLINIANA*
- u. Perigynia usually without nerves on the upper face, only weakly nerved on the lower face; perigynia more appressed or closely ascending, somewhat flattened, much wider than thick, with the inner face flattish; rare 75a. *C. COMPLANATA* var. *COMPLANATA*
- s. Topmost (terminal) flower spike all staminate (male) flowers v
- v. Perigynia with a minute roughened (scabrous) puberulence; no purple-red or wine-purple color at base of plant; beak of perigynium curved, nearly as long as main body of perigynium 79. *C. SCABRATA*
- v. Without the above combination; perigynia with short or long, sparse or dense hairs; purple-red or wine-purple color at base of plant; beak of perigynia, if present, straight w
- w. Plants of wet or swampy ground, forming large colonies with creeping rhizomes; pistillate spikes 10-90 mm. long, much longer (3-6 times) than thick; culms mostly 5-12 dm. tall x
- x. Perigynia 2.5-5 mm. long; pistillate spike 3-8 mm. thick; no raised lines or ribs showing on surface of perigynia 78. *C. LANUGINOSA*
- x. Perigynia 5-10 mm. long; pistillate spike 8-15 mm. thick; faint or prominent raised lines or ribs showing on surface of perigynia y
- y. Ribs strong or prominent on perigynia; perigynia ending in 2 conspicuous teeth 0.7-2.7 mm. long 98. *C. TRICHOCARPA*

- y. Ribs weak or faint on perigynia; perigynia ending in 2 short teeth 0.5–1 mm. long 95a. *C. × SUBIMPRESSA*
- w. Plants of dry ground or dry rocky places, forming tufts or clumps; pistillate spikes mainly 3–9 mm. long, either as thick as long or only slightly longer (1½–2 times) than thick; culms mostly 0.5–5 dm. tall 2
- z. Main body of perigynium about as long as wide, at maturity not or very slightly 3-angled 1
1. Plant with elongated horizontal scaly stolons at base (plants must be dug up completely to show this); base of leafy shoots conspicuously fibrillose; ligule at summit of leaf-sheath short, much wider than long; leaf-blades 1–3 mm. wide; plants of acid soils of northern and central Missouri 44. *C. PENNSYLVANICA*
1. Plant without long horizontal stolons; base of leafy shoots faintly or not fibrillose; ligule at summit of leaf-sheath prominent, longer than wide; leaf-blades 3–7 mm. wide; plants of wooded limestone slopes of southwestern Missouri 45. *C. COMMUNIS*
- z. Main body of perigynium longer than wide, at maturity noticeably 3-angled 2
2. Leaves mainly 3–7 mm. wide; ligule at summit of leaf-sheath prominent, longer than wide; perigynia about 1.5 mm. thick 45. *C. COMMUNIS*
2. Leaves 0.5–3 mm. wide; ligule at summit of leaf-sheath, short, wider than long; perigynia 0.5–1.3 mm. thick 3
3. Base of plant with elongated horizontal scaly stolons; staminate spike usually with a short stalk; perigynia whitish-green 43. *C. PHYSORHYNCHA*
3. Base of plant without elongated horizontal stolons; staminate spike usually sessile (without a stalk); perigynia olive green or dull green 4
4. Common plant throughout Missouri; scales of staminate spike often dark or purplish or purple-red; pistillate spikes usually not bunched together; staminate spike 3–15 mm. long; scales of staminate spike obtuse (blunt) or short-pointed, closely appressed; flowering culms upright, rather stiff 41. *C. ARTITECTA*
4. Rare plant of southeastern Missouri lowlands; scales of staminate spike often green or green and brown; pistillate spikes, at least the upper ones, bunched together; staminate spike 3–8 mm. long; scales of staminate spike pointed, ascending or loosely spreading; flowering culms curving, arching, or spreading, weak 42. *C. NIGROMARGINATA*
- n. Perigynia glabrous or nearly so (roughened, toothed, or serrulate margins of beaks are included here) 5
5. Leaves thread-like, 0.5–1.5 mm. wide (mainly 1 mm. or less); growing in the crevices and ledges of limestone bluffs; 2–4 thread-like peduncles appearing from the top of the main peduncle; perigynia 1.5–2 mm. long; stigmas 3 and achenes 3-sided 49. *C. EBURNEA*
5. Without the above combination of characters 6
6. Lowermost broadest basal leaves (overwintering or last year's) mostly 15–40 mm. wide (rarely 10), bluish- or gray-green; no purple or red-purple color at base of plant; plants mainly of north-facing or east-facing wooded limestone slopes; stigmas 3 and achenes 3-sided; perigynia with rounded angles at least below the middle. 57. *C. ALBURSINA*
6. Without the above combination of characters 7
7. Pistillate spikes globose or nearly globose (ball-like or spherical); perigynia 10–20 mm. long; 1 staminate (male) spike at the top of the inflorescence 8
8. Found throughout the state, including the southeastern section; perigynia cuneate (tapering inward or narrowed) at the base, not shining; staminate spike often sessile (without a stalk) 103. *C. GRAYII*
8. Found only in southeastern Missouri lowland section; perigynia rounded at base, shining; staminate spike usually with a long peduncle (stalk) 104. *C. INTUMESCENS*
7. Without the above combination of characters 9
9. Lowest scale of pistillate flower prolonged, green, and leaf-like, 15–50 mm. long (do not confuse this with a leaf-like bract at base of a flowering spike); each culm with only 1 spike with 2–4 perigynia; all flowering culms much shorter than the dense clump of dark green leaves; styles 3; body of perigynium rounded, globe-shaped, abruptly tapering to a long beak; plants of rich low woods or wooded slopes 40. *C. JAMESII*
9. Without such a combination of characters; no leaf-like pistillate scales, all reduced in size and less than 10 mm. long (the leaf-like bract at base of the pistillate inflorescence may be greatly prolonged but should not be confused here with the lowest pistillate scale) 10
10. Flowering culms 1–10 cm. tall; most or all of the flowering culms much shorter than the leaf-blade, the pistillate spikes hidden in the densely tufted leaf-bases (remains of

- old fruiting stalks [peduncles] may be found among the leaf-bases; do not confuse leaf-like bracts of inflorescence with ordinary leaf-bases); flowering peduncles of a culm not alike, 1 elongated with staminate or staminate and pistillate flowers, the other 1-3 very short and pistillate only 48. *C. TONSA*
10. Without the above combination of characters 11
11. Each culm with only 1 spike, the male flowers at the top; leaves all thread-like, 0.5-1.3 mm. wide; plants of limey open swampy meadows or at the base of moist shaded limestone river bluffs; perigynia beakless, 2.5-3.5 mm. long; styles 3 39. *C. LEPTALEA*
11. Without the above combination of characters 12
12. Styles 3; achenes (inside perigynia) 3-sided or 3-angled 13
13. Topmost (terminal) flower spike with pistillate (female) flowers in the upper part and staminate (male) flowers at the base 14
14. Mature pistillate spikes 10-22 mm. thick; mature perigynia 3.5-8.5 mm. long; beak at the summit of perigynium 2-3.5 mm. long 15
15. Beaks of mature perigynia widely to nearly horizontally spreading; style strongly curved near its base (look inside perigynium); scales of pistillate flowers with an awn or sharp point at tip 100. *C. SQUARROSA*
15. Beaks of mature perigynia upwardly pointing or ascending; style nearly or quite straight (look inside perigynium); scales of pistillate flowers mainly blunt or only a short point at tip. 101. *C. TYPHINA*
14. Mature pistillate spikes 2-8 mm. thick; mature perigynia 2-4 mm. long; perigynium either without a beak or the beak at most 1.5 mm. long 16
16. Some or all of the pistillate spikes drooping, nodding, or spreading at maturity on thread-like peduncles (stalks) nearly equaling the length of the spikes 16a
- 16a. Pistillate spikes narrowly linear, 10-12 times longer than thick, 2-3 mm. thick 68. *C. GRACILLIMA*
- 16a. Pistillate spikes cylindric, oblong-cylindrical or linear, 4-7 times longer than thick, 5-7 mm. thick 70. *C. DAVISII*
16. Pistillate spikes erect to ascending at maturity, either sessile (no stalk) or at least the upper ones nearly sessile or with a short stalk 17
17. Only 2-4 leaves present at base of culm (stem); leaves pale green and glaucous (bluish-green); perigynia whitish 82. *C. BUXBAUMII*
17. Leaves at base of culm more numerous; leaves olive or dark green, not glaucous; perigynia olive green to dark brown 18
18. Pistillate spikes mostly $3\frac{1}{2}$ -7 times as long as thick; leaf-blades 4-10 mm. wide; perigynia without nerves on the faces, the tip or upper half of mature perigynium spreading outward (suarrose) 19
19. Perigynium with a beak 1-1.5 mm. long; pistillate spikes 7-8 mm. thick; rarely found 80a. *C. x DEAMII*
19. Perigynium beakless or with only a minute beak less than 0.5 mm. long; pistillate spikes mostly 3.5-6 (up to 7) mm. thick; common throughout Missouri 80. *C. SHORTIANA*
18. Pistillate spikes mostly $1\frac{1}{2}$ -3 times as long as thick; leaf-blades 1.5-5 mm. wide; perigynia with 1 or more nerves on at least one of the faces, the tip or upper half continuing in the same direction as the rest of the perigynium 20
20. Perigynia usually without nerves on the upper face, only weakly nerved on the lower face; perigynia closely ascending or appressed, somewhat flattened, much wider than thick, with the inner face flattish; rare 75a. *C. COMPLANATA* var. *COMPLANATA*
20. Perigynia conspicuously nerved on both faces; perigynia spreading, plump, about equally rounded on outer and inner faces, nearly as thick as wide; common species 76. *C. CAROLINIANA*
13. Topmost (terminal) flower spike with all the flowers staminate (male) 21
21. Perigynia minutely roughened (scabrous); beak of perigynium curved, nearly as long as the body of perigynium 79. *C. SCABRATA*
21. Without the above combination; perigynia glabrous or smooth; beaks of perigynia straight or bent 22
22. Beak of perigynium abruptly bent or turned to one side 23

23. Perigynia rounded or at least not long tapering at the base, rounded in cross-section, loosely surrounding the achenes, dark brown or olive green 60. *C. GRANULARIS*
23. Perigynia tapering and conspicuously narrowed at the base, 3-sided, closely surrounding the achenes, whitish, pale green, gray-green, or pale brown 24
24. Pistillate scales usually purplish brown on each side of midrib; plants with underground elongated rootstocks; leaves gray-green or glaucous, stiffish, most of them at base of plant; plants of limestone glades and prairies 51. *C. MEADII*
24. Without the above combination of characters; pistillate scales pale green or greenish-white; plants growing in tufts, without creeping rootstocks; leaves mostly dark or dull green, soft, scattered on the plant; plants of dry or wet woodland 25
25. Dark purplish-red, reddish-brown, mahogany-red, or similar color at base of plant; staminate spike on usually a long peduncle (stalk) 1-4 cm. long standing well above the uppermost pistillate spike; scales of staminate spike usually tinged brown or purplish; beak of perigynium snout-like, long and narrow 59. *C. GRACILESCENS*
25. Green or pale to dull brown color at base of plant; staminate spike either sessile (stalkless) or on a very short peduncle, very close to and not much, if any, longer than the uppermost pistillate spike; scales of staminate spike usually greenish-white to whitish; beak of perigynium short and broad 58. *C. BLANDA*
22. Beak of perigynium, if present, straight or slightly curved, not abruptly bent or turned to one side 26
26. Mature perigynia 10-20 mm. long 27
27. Perigynia widely or nearly horizontally spreading at maturity, the beak 2-3 times as long as the inflated body of the perigynium; achene broader than long, nearly straight across (subtruncate) at summit 108. *C. GIGANTEA*
27. Perigynia either closely overlapping and appressed to one another or spreading-ascending at maturity, but not horizontally widely spreading, the beak shorter or at most somewhat longer than the inflated body of the perigynium; achene longer than broad or as broad as long, tapering or narrowed above to the summit 28
28. Pistillate spikes short-cylindric to broadly oblong-cylindric, mainly $1\frac{1}{2}$ -2 times longer than thick; achene (inside perigynium) much longer than broad, the angles not prominently knobbed, the sides flat or nearly so 29
29. Common species throughout Missouri; culms (stems) bunched together in tufts; perigynia closely overlapping, appressed-ascending, 13-20 mm. long; scales of pistillate spikes long-tapering or awned at tip; leaf-blades mainly 5-15 mm. wide 106. *C. LUPULINA*
29. Found only in the southeastern lowland section; culms not bunched, arising solitary or a few from a creeping elongated rootstock; perigynia spreading-ascending, loosely arranged, 10-14 mm. long; scales of pistillate spikes blunt (obtuse) to short-pointed (acute); leaf-blades 2-6 mm. wide 105. *C. LOUISIANICA*
28. Pistillate spikes long-cylindric, mainly 2-4 times longer than thick; achenes about as broad as long, the angles prominently knobbed, the sides deeply sunken in center (concave) 107. *C. LUPULIFORMIS*
26. Mature perigynia 2-9 mm. long (or, if 10 mm. or more, the pistillate spikes either 2-4 mm. thick or drooping or on slender thread-like peduncles) 30
30. Perigynium ends in a prominent 2-toothed or 2-pronged beak, the teeth of the beak 0.2-2.2 mm. long 31
31. Pistillate spikes very slender, linear-cylindric, 10-15 times longer than thick, 2-4 mm. thick, the lower drooping or spreading; perigynia only faintly nerved at the base, otherwise nerveless; base of achene raised on a stalk 0.5-1.5 mm. long 71. *C. DEBILIS*
31. Pistillate spikes thick-cylindric to shortly oblong, mostly 2-5 times longer than thick, mainly 4-20 mm. (rarely 3) thick, erect to drooping; perigynia usually many-nerved or ribbed, rarely nerveless; base of achene without a stalk 32
32. Plants of limestone glades or upland limey soils; pistillate spikes 10-23 mm. long, 3-7.5 mm. thick; low plants with creeping rootstocks, the culms mainly 1-2 dm. tall; leaves glaucous, 3-15 cm. long, the short basal ones 3-10 cm. long; perigynia 3-4.5 mm. long 62. *C. MICRODONTA*
32. Without the above combination of characters; plants of wet or swampy ground of valleys and lowlands; pistillate spikes mainly 25-105 mm. (rarely 10) long, mainly 4-13 mm. thick; taller plants, the mature ones usually 3-15 dm. tall; basal and other leaves generally much longer, 30-100 cm. long; perigynia mainly 4-9 mm. long 33

- 33. Main body of perigynium (excluding its beak) broadest in the upper half; all scales of pistillate spike with a long awn much longer than the length of the perigynium; perigynia 3.5-5 mm. long . 99. C. FRANKII
- 33. Main body of perigynium broadest in the lower half; scales of pistillate spike mostly shorter than or equaling the length of the perigynia (in some cases slightly exceeding); perigynia mainly 5-9 mm. long 34
- 34. Staminate spike only 1 on each flowering culm; scales of pistillate flowers tipped with a rough (scabrous) awn which is equal to or longer than the main body of the scale 35
- 35. No red-purple or wine-purple color at base of plant; most of the mature perigynia, or at least the lower ones, pointing downward (reflexed); teeth of the beak 1.2-2.2 mm. long, outwardly arching 91. C. COMOSA
- 35. Red-purple or wine-purple color at base of plant; mature perigynia ascending or spreading, not reflexed; teeth of the beak 0.1-1 mm. long (averaging 0.5 mm. long) 36
- 36. Scales of staminate spike with a short slender tip or a short abrupt cusp at tip; all pistillate spikes erect or ascending, narrowed or tapering at base; perigynia erect or strongly ascending; culms (stems) not in clumps, but 1 or few from long-creeping underground rhizomes 93. C. SCHWEINITZII
- 36. Scales of staminate spike tipped with a rough (scabrous) awn; at least the lower mature pistillate spikes drooping or spreading, not narrowed or tapering at base, but about as thick at base as higher up; perigynia spreading or spreading-ascending; culms growing in clumps. 37
- 37. Perigynia with 12-20 nerves; teeth of perigynia spreading or ascending; mature perigynia 1.5-2 mm. thick, only barely inflated 90. C. HYSTRICINA
- 37. Perigynia with 7-10 nerves; teeth of perigynia erect or very close to one another; mature perigynia mostly 2.5-3 mm. (2-4) thick, conspicuously inflated 92. C. LURIDA
- 34. Staminate spikes 2-6 on each flowering culm; scales of pistillate spike smooth or rough-tipped, with or without an awn 38
- 38. Plants growing in large colonies from creeping underground rhizomes; perigynia of thick or firm texture, either smooth and without nerves or with many (12-25) conspicuous, delicately impressed or barely elevated nerves 39
- 39. Rarely with wine-red or wine-purple at base of plant; leaves glaucous or pale bluish-green; mature perigynia smooth and without nerves or with fine, impressed or barely elevated nerves 95. C. HYALINOLEPIS
- 39. Purple-red or wine-purple commonly at base of plant; leaves grass-green; mature perigynia with conspicuous strong ribs or nerves 40
- 40. Teeth at end of perigynia 1-2.2 mm. long; the inner band of the middle and upper leaf-sheath conspicuously feather-veined (pinnate) at the summit; leaf-blades mainly 2-6 mm. (-8) wide 97. C. LAEVICONICA
- 40. Teeth at end of perigynia averaging 0.5 mm. (0.3-1) long; no feather-veined (pinnate) summit on the inner band of the leaf-sheath; leaf-blades mainly 8-15 mm. (rarely only 6) wide 94. C. LACUSTRIS
- 38. Plants growing in dense clumps, not in large colonies; mature perigynia thin or papery, 7-10-nerved 102. C. VESICARIA var. MONILE
- 30. Tip of perigynium ends abruptly and cut off straight across or at an angle (obliquely), either without teeth or with only a slight notch without conspicuous projections 41
- 41. At least the lower mature pistillate spikes spreading, nodding, or drooping from very slender peduncles (stalks supporting inflorescences) 42
- 42. Pistillate spikes many-flowered (10-60 or more); perigynia tapering into an obvious or prominent beak 1-2 mm. long 43
- 43. Red-purple or wine-purple color at base of plant; pistillate spikes very slender, linear-cylindric, 10-15 times longer than thick, 2-4 mm. thick; perigynia 6-10 mm. long, only faintly nerved at the base, otherwise nerveless; base of achene raised on a stalk 0.5-1.5 mm. long 71. C. DEBILIS
- 43. Shades of brown at base of plant; pistillate spikes thick-cylindric, 3-5 times longer than thick, 5-10 mm. thick; perigynia 4-6 mm. long, strongly nerved; base of achene without a stalk 44
- 44. Scales of pistillate spike with a rough (scabrous) awn projecting at the tip; mature perigynia squarrose (outwardly spreading or curving from the center), broadest at or above the middle 81. C. JOORI

44. Scales of pistillate spike with a smooth sharp-pointed (acuminate) tip; mature perigynia erect or straight, not curving outward or squarrose, broadest in the lower half. 72. *C. CHEROKEENSIS*
42. Pistillate spikes mainly with only 3-9 flowers; perigynia without any beak or the beak, if present, less than 1 mm. long. 45
45. Leaf-blades 1.5-5 mm. wide, dull or dark green, not glaucous or gray-green; pistillate spikes without any staminate (male) flowers at the base. 55. *C. DIGITALIS*
45. Leaf-blades 6-15 mm. wide, glaucous or gray-green; pistillate spikes with 1-2 staminate (male) flowers or empty scales at base. 56. *C. LAXICULMIS*
41. Mature pistillate spikes erect or ascending. 46
46. Lowermost basal leaves mainly 10-17 mm. wide (less often 8), forming an evergreen spreading rosette; base of leaf-tufts, culms, and sheaths of bracts of the inflorescence dark red- or maroon-purple. 54. *C. CAREYANA*
46. Without the above combination of characters. 47
47. Pistillate spikes with only 1-9 perigynia. 48
48. Plants of limestone glades and prairies, rarely in wet meadows, with horizontally creeping underground slender rootstocks or superficial stolons; perigynia glaucous (whitish) or pale greenish, with several strong ribs at maturity; scales of pistillate spikes with usually purplish-brown margins. 49
49. Common species throughout Missouri on limestone glades and prairies; with horizontally creeping underground slender rootstocks; leaves glaucous, gray- or blue-green, stiffish; lower leaf-sheaths bearing leaf-blades; lower pistillate spike 5-10 mm. thick; perigynia usually in 6 rows in the spike, mostly overlapping, 2-2.5 mm. wide. 51. *C. MEADII*
49. Rare species, known only from swampy meadows in Howell County; with superficial stolons at the base of plant; leaves green, thin; lower leaf-sheaths mostly without leaf-blades; lower pistillate spikes 3-5 mm. thick; perigynia alternate-flowered, in 2 rows in the spike, at least the lower not overlapping, 1.5-2 mm. wide. 53. *C. WOODII*
48. Plants growing in clumps or bunches, without horizontally creeping rhizomes or stolons; perigynia dull or dark green or brown, not glaucous, either with many fine lines (striate) or impressed nerves, but not with strong elevated ribs; scales of pistillate spikes mostly pale green and white to pale or dull brown, rarely tinged with red. 50
50. Perigynia more or less narrowed or tapering from the middle to the base. 51
51. Scales of pistillate spike acute or only short-pointed, smooth; perigynia with distinct elevated nerves; peduncles (supporting stalk) of at least the lower pistillate spikes much elongated, longer than their own length as well as their leaf-sheath; base of plant dull green, drab, or brownish. 55. *C. DIGITALIS*
51. Most of the scales of the pistillate spike with long rough (scabrous) awns; perigynia with many impressed nerves, producing a vertically wrinkled or lined surface; peduncles of the lower pistillate spikes slightly longer than the leaf-sheath; base of plant dark wine-red purple or brown-purple, sometimes brown or greenish-white. 52
52. Base of plant always dark purplish-red or reddish-purple; leaf-blades mainly 2-3 mm. (-5) wide; perigynia very loosely alternately scattered, the tip of the lowest perigynia in the spikelets barely or not reaching the base of the next higher perigynia on the same side of the rachis; perigynia abruptly constricted at the tip into a short beak, definitely 3-angled and nearly completely filled to the top by the achene; lowest leaf-like bract (at base of lowest pistillate spike) usually shorter than the uppermost spikes; lowest leaves of plant usually much shorter than the culms; staminate spike conspicuous, usually on a long peduncle (stalk) often 2-3 or more cm. long and projecting usually 2-5 cm. above the uppermost pistillate spike. 63. *C. OLIGOCARPA*
52. Base of plant variable in color, some with greenish-white or brown, others with dark brown-purple or reddish-purple; leaf-blades mainly 3-10 mm. wide; perigynia more or less closely overlapping, in at least the uppermost pistillate spike with the tip of the perigynium usually reaching to and above the base of the next higher perigynium on the same side of the rachis; perigynia usually more gradually tapered, curving, or rounded

- at the tip (sometimes more abruptly constricted as in *C. oligocarpa*, in which case use other key characters), the sides mostly curved or rounded (sometimes more definitely angled, in which case use other key characters), mainly empty inside above and not filled by the achene, much longer than the achene; lowest leaf-like bract usually equaling or longer than the uppermost spikes; lowest leaves of plant nearly equaling or only slightly shorter than the culms; staminate spike nearly or quite sessile, usually inconspicuous and projecting usually only 0.5–2 cm. beyond uppermost pistillate spike 66. *C. AMPHIBOLA*
50. Perigynia round or broadened at the base 53
53. Leaves firm, more or less glaucous (silvery-white) or gray-green, or pale green; sheaths of the bracts at the base of the spikes enlarged and loose at summit; scales of pistillate spike smooth-tipped with a long point or short awn, usually shorter than or at most equaling the length of the mature perigynia 67. *C. FLAGGOSPERMA*
53. Leaves thin, grass-green or dull or dark green, not glaucous; sheaths of the bracts at the base of spikes tight and narrowly cylindrical, not enlarged at summit; scales of pistillate spikes with a conspicuous long and rough (scabrous) awn, usually longer than the perigynia 66. *C. AMPHIBOLA*
47. Pistillate spikes usually with 10–60 perigynia 54
54. Leaf-like bract of the lowest pistillate spike without a sheath or nearly without one; base of plant conspicuously chestnut brown; scales of pistillate spike with a rough (scabrous) awn; mature perigynia squarrose (outwardly spreading or curving from the center), broadest at or above the middle 81. *C. JOORI*
54. Without the above combination of characters; leaf-like bract of the lowest pistillate spike with an elongated tubular closed sheath; base of plant silvery, green, brown, purple, or reddish-tinged 55
55. Staminate spike very conspicuous, usually on a prominent long peduncle (stalk) much longer than the uppermost pistillate spike; plants of open limestone glades, and wet or dry prairies, rarely of wet meadows 56
56. Perigynia glaucous (whitish) or pale greenish, with several strong ribs at maturity, broadest in the upper half, narrowed toward the base; scales of pistillate spikes usually with purplish-brown margins; perigynia closely enveloping the achene 57
57. Rare plant of swampy meadows in Howell County; with superficial stolons at the base of plant; lower leaf-sheaths mostly without leaf-blades; perigynia alternate-flowered, in 2 rows in the spike, at least the lower not overlapping 53. *C. WOODII*
57. Common plants of limestone glades and prairies (except for the rare *C. tetanica*); with horizontally creeping underground slender rootstocks; lower leaf-sheaths bearing leaf-blades; perigynia in 3 or 6 rows in the spike, more crowded and overlapping 58
58. Common plant of limestone glades and prairies; leaves glaucous, gray- or blue-green, stiffish; lower pistillate spike 5–10 mm. thick; perigynia usually in 6 rows in the spike, 2–2.5 mm. wide, more or less spreading and inflated when mature, with an abruptly narrowed tip, somewhat turned or curved to one side 51. *C. MEADII*
58. Rare, known only from dry prairie in Atchison County, northwestern Missouri; leaves green, rather thin or membranous; lower pistillate spike 3–4.5 mm. thick; perigynia usually in 3 rows in the spike, 1.5–2.2 mm. wide, appressed or straight and not inflated when mature; without any curvature at the tip 52. *C. TETANICA*
56. Perigynia dull or dark green or brown, not glaucous, with many vertically lined impressed nerves or nearly nerveless or few-nerved, broadest at the base or in the lower half, rounded at the base; scales of pistillate spikes either pale green and white or pale or dull brown with white or green, rarely tinged purplish or reddish; perigynia loosely enveloping the achene 59
59. Plants of limestone glades in the Ozark region; culms solitary, arising from horizontally creeping underground rootstocks; leaf-blades glaucous, gray- or blue-green, stiffish; perigynia with a few raised nerves, often resinous-dotted 61. *C. CRAWEI*
59. Rare plant of dry prairie in Callaway and Phelps counties; culms several in a dense clump; leaf-blades deep green, not stiffish; perigynia with many vertically lined impressed nerves, not resinous-dotted 65. *C. CONOIDEA*

55. Staminate spikes either sessile or shortly stalked, close to, shorter, and almost hidden by uppermost pistillate spike (in some variations of *C. amphibola* the staminate spike is more prominently raised on a longer stalk exceeding the uppermost pistillate spike); shade-loving plants typically of rich, moist, dry or rocky woodlands, or on moist shaded bluffs and banks along streams . . . 60
60. Scales of pistillate spikes usually only $1/3$ – $1/2$ length of perigynia, either short-pointed or with a short inconspicuous smooth awn 1 mm. or less long; leaves often or usually glaucous (whitish or silvery) and firm or thickish . . . 61
61. Perigynia 2–4 mm. long, with strong elevated nerves, the tip of the mature perigynium bent over or curving outward (scurrose), or straight in one variety; pistillate spikes mainly 3–5 mm. thick; sheaths of leaf-like bracts tight and not enlarged at the summit . . . 60. *C. GRANULARIS*
61. Perigynia mostly 3–6 mm. long, with fine slender nerves, the tip of the perigynium straight; pistillate spikes 5–8 mm. thick; sheaths of leaf-like bracts enlarged and loosened at the summit . . . 67. *C. FLACCOSPERMA*
60. Most of the scales of pistillate spikes usually equal or longer than the perigynia, with a conspicuous rough (scabrous) awn usually 1–4 mm. long (scales sometimes shorter than perigynium, but still prominently rough-awned); leaves usually dull or dark green, more rarely glaucous . . . 66. *C. AMPHIBOLA*
12. Styles 2; achenes (inside perigynia) 2-sided or 2-angled . . . 62
62. Uppermost spike completely staminate (male); lower or lowermost spikes completely pistillate (female) or some of the spikes all staminate and some all pistillate . . . 63
63. Inflorescence a more or less continuous cluster 15–60 mm. long, of very short crowded spikes, each of the spikes only slightly longer than broad and only 4–12 mm. long, often not distinguishable from one another . . . 64
64. Upper leaf-sheaths green and finely lined (striate) on the inner (ventral) side; beak of perigynium $1/4$ – $1/3$ as long as main body of perigynium . . . 3. *C. SARTWELLII*
64. Upper leaf-sheaths transparent (hyaline) or brown, not finely lined on the inner (ventral) side; beak of perigynium $1/2$ – $5/8$ as long as main body of perigynium . . . 65
65. Culm smooth below the spikes . . . 2. *C. DOUGLASII*
65. Culm rough below the spikes . . . 1. *C. PRAEGRACILIS*
63. Inflorescence of distinctly separated spikes which are several to many times (3–20) longer than broad . . . 66
66. At least the lower scales of pistillate spikes with a long bristle-like awn mostly 2–4 times as long as the perigynia (sometimes only slightly longer than perigynia); pistillate spikes usually nodding or arching; tip of perigynium not 2-toothed; face of perigynium without 2–4 ribs . . . 89. *C. CRINITA*
66. Without the above combination of characters; scales of pistillate spikes blunt (obtusate) or acute to sharp pointed (cuspidate), rarely with a short awn, usually shorter than or somewhat longer than the perigynia; pistillate spikes erect to drooping or arching; tip of perigynium either entire or 2-toothed; face of perigynium nerveless or with 2–4 strong ribs . . . 67
67. Beak of perigynia with 2 small teeth at the summit; in addition to the rib on each side, the perigynia have 2–4 strong nerves on each face . . . 84. *C. NEBRASKENSIS*
67. Beak of perigynia entire or cut off flat on the top or at least without 2 small teeth at the summit; faces of perigynia completely nerveless or with 1 or 2 faint nerves if any . . . 68
68. At least the lowest mature pistillate spikes widely spreading, arching, or drooping; tip of mature perigynium twisted or bent and rather conspicuous when dry . . . 88. *C. TORTA*
68. Pistillate spikes erect or definitely ascending; tip of mature perigynium when dry not twisted, but more or less flat and straight . . . 69
69. Leaves usually glaucous (silvery or gray mixed with green); plants usually in small tufts of few culms; flowering or fruiting (fertile) culms surrounded at the base by the dried-up leaves of the previous year; flowering or fruiting culms shorter than or at most as long as the leaves; lowest leaves of the current year possessing leaf-blades (phyllopodic); mature perigynia mainly 2.7–3.1 mm. long . . . 83. *C. AQUATILIS* var. *ALTIOR*
69. Leaves grass- or dark green, not glaucous; plants in dense large clumps, beds, or patches; flowering or fruiting (fertile) culms arising laterally (at

- the side), not surrounded at the base by the dried-up leaves of the previous year; flowering or fruiting culms usually longer or taller than the clump of leaves; lowest leaves of the current year with sheaths only, without leaf-blades (aphyllopodic); mature perigynia mainly 2-2.7 mm. long . . . 70
70. Plants of the wet limey meadows of the Ozark section; at least some of the lowest leaf-sheaths consisting of thread-like or fiber-like parts on the inner (ventral) side. . . 87. *C. STRICTA*
var. *STRICTIOR*
70. Plants along banks of streams throughout Missouri, or prairies or along railroads of northern Missouri; lowest leaf-sheaths without thread-like or fiber-like parts . . . 71
71. Plants mostly of prairie habitats along railroads of northern Missouri; mature perigynia inflated, each side convex (bulging at center); scales of pistillate spike loose, somewhat spreading away from the perigynia at maturity, sharp-pointed or slender-tipped; ligule at summit of leaf-sheath usually slightly longer than wide; pistillate spikes 10-40 mm. (averaging 12-27) long . . . 85. *C. HAYDENII*
71. Plants most commonly found along banks of streams throughout Missouri; mature perigynia not inflated, rather closely enveloping the achene; scales of pistillate spike appressed-ascending, close to or pressed against the perigynia, obtuse (blunt) to acute; ligule at summit of leaf-sheath usually wider than long; pistillate spikes 20-100 mm. long . . . 86. *C. EMORYI*
62. All the spikes alike or nearly so and/or with both staminate (male) and pistillate (female) flowers in the same spike (where stamens have fallen or disappeared from mature or old spikes, the location of the staminate flowers may usually be detected by the empty scales at base or tip of spike) . . . 72
72. Plants with long black or brown creeping rootstocks; the culms (stems) arising solitary or few together . . . 73
73. Upper leaf-sheaths green and finely lined (striate) on the inner (ventral) side; beak of perigynium $1/4-1/3$ as long as main body of perigynium . . . 3. *C. SARTWELLII*
73. Upper leaf-sheaths transparent (hyaline) or brown, not finely lined on the inner (ventral) side; beak of perigynium $1/2-5/8$ as long as main body of perigynium . . . 74
74. Culm smooth below the spikes . . . 2. *C. DOUGLASHII*
74. Culm rough below the spikes . . . 1. *C. PRAEGRACILIS*
72. Plants growing in close tufts or clumps, the leafy shoots and those with flowers or fruits arising from a non-creeping or compact base . . . 75
75. Scales of the pistillate flowers (located by the perigynia) rounded or obtuse (blunt) at tip, not tapering or slender-pointed . . . 76
76. Plants usually of wooded situations, throughout Missouri; lower part or base of mature perigynium corky, spongy, or soft-thickened as contrasted with the firmer upper part; some or all of the spikes with the staminate (male) flowers at the top, pistillate (female) flowers at the base and middle of the same spike (where stamens have fallen or disappeared from mature or old spikes, the location of the staminate flowers may usually be detected by the empty or closely overlapping or bunched scales at the tip or base of the individual spikes) . . . 77
77. Stigmas long, slender, straight, not twisted; perigynium more or less gradually tapering into a beak . . . 6. *C. ROSEA*
77. Stigmas shorter, stout, twisted; perigynium more abruptly contracted or narrowed into a beak . . . 5. *C. CONVOLUTA*
76. Plants typically of swampy limey meadows or on dripping limestone ledges at the base of bluffs, only in the Ozark section; mature perigynia firm throughout, not corky nor soft spongy-thickened at base; at least the topmost (terminal) spike with the staminate (male) flowers at the base . . . 23. *C. INTERIOR*
75. Scales of the pistillate flowers (with the perigynium) short- to long-pointed or awned at the tip, at least tapering or narrowed at the tip . . . 78
78. Staminate (male) flowers located at the tip of some or all of the spikes (where stamens have fallen or disappeared from mature or old spikes, the location of the staminate flowers may usually be detected by the empty or closely overlapping or bunched scales at the top of the individual spikes) . . . 79
79. Lower part or base of mature perigynium corky, spongy, or soft-thickened as contrasted with the firmer upper part (test the perigynium with a dissecting needle or pin) . . . 80
80. Margins of the perigynia, including their beak, smooth (use 10 × magnifying lens) . . . 81

81. Common throughout the Ozark section, usually in dry or rocky woodland or on ledges of bluffs; lower $1/2$ to $2/3$ of mature perigynia spongy and distinctly nerved or with vertical lines 4a. *C. RETROFLEXA* var. *RETROFLEXA*
81. Known only from wet woodland in Dunklin County, southeastern Missouri; only the lowest $1/4$ or $1/5$ part of the mature perigynia spongy, not nerved on the inner side 4b. *C. RETROFLEXA* var. *TEXENSIS*
80. Upper margins of body or beak of perigynium minutely roughened or serrulate (saw-toothed) (use magnifying lens of $10\times$) 82
82. Leaf-blades 1–3 (–4) mm. wide; lowest bract (at base) of inflorescence greatly prolonged and leaf-like, 50–200 mm. long, 1–2 mm. wide; inflorescence 6–8 mm. thick, simple and unbranched, all the spikes arising directly from the main axis (rachis) with 1 spike at each node of the axis; leaf-sheaths tight and closely enveloping the culms; culms firm and slender 9. *C. ARKANSANA*
82. Leaf-blades mainly 3–17 mm. (rarely 2.5) wide; inflorescence without a lowest bract or lowest bract not conspicuous or elongated; inflorescence 7–40 mm. thick, compound, with 2 or more spikes placed on at least the lowest lateral (side) branch from the main axis; leaf-sheaths loose, not closely enveloping the culms, the inner thinner (ventral) side (the thinner side without vertical ribs or stripes) either with tiny brown- or purple-red dots or cross-wrinkled (seen especially when old or dried); culms rather soft and flattened 83
83. Beak of perigynium shorter than the length of the main body of the perigynium; the flat inner face of the perigynium not nerved or with short nerves only at base 84
84. Inner (ventral) side (the thinner side without vertical ribs or stripes) of leaf-sheath cross-wrinkled; leaf-blades mainly 5–10 mm. wide; scales of pistillate flowers whitish 22. *C. CONJUNCTA*
84. Inner thinner (ventral) side of leaf-sheath not cross-wrinkled; leaf-blades mainly 2.5–4.5 (–5) mm. wide; scales of pistillate flowers brownish or tinged brown 18. *C. OKLAHOMENSIS*
83. Beak of perigynium as long as or longer than length of the main body of perigynium; the flat inner face of the perigynium either strongly nerved, or, if not nerved, the perigynium very long-beaked or of a lanceolate shape and tapering into the beak 85
85. Beak of perigynium 2–3 times the length of the main body of perigynium; mature perigynia abruptly enlarged at base and noticeably wider there, not nerved or faintly nerved on the flat inner side; inner (ventral) side of leaf-sheath red-purple dotted but not cross-wrinkled 21. *C. CRUS-CORVI*
85. Beak of perigynium about as long as or $1\frac{1}{2}$ (rarely 2) times length of main body of perigynium; mature perigynium with the base continuous with the rest of the body, tapering gradually, not abruptly enlarged at base, strongly nerved on the flat inner side; inner thinner (ventral) side of the leaf-sheath either cross-wrinkled, or (as in *C. laevivaginata*) not cross-wrinkled 86
86. Leaf-sheaths with a thin summit which is prolonged as a loose membranous projection beyond the base of the leaf-blade; inner thinner (ventral) side of the leaf-sheath usually cross-wrinkled 19. *C. STIPATA*
86. Leaf-sheaths with a thick-margined summit which is sunken in the middle (concave) or nearly straight-edged (subtruncate); inner thinner (ventral) side of leaf-sheath not or rarely cross-wrinkled 20. *C. LAEVIVAGINATA*
79. Perigynia not corky, spongy, or softer-thickened at the base, but firmer throughout from base upward 87
87. Plants of sink-hole ponds; inflorescence compound, with conspicuous side branches, some of the lower branches up to 4 cm. long; perigynium abruptly contracted into a beak, broadest above the middle and tapering at the base, 2–2.6 mm. long, nearly as broad as long; 1 or both sides of perigynium bulged out in the middle, olive-brown to black 17. *C. DECOMPOSITA*
87. Plants not of sink-hole ponds, but if so, then without the above combination; inflorescence without conspicuous side branches or these not usually elongated; perigynia broadest at the base or at the middle; perigynium flat on at least one side, greenish, straw-colored, yellow, or brown 88
88. Leaf-sheaths loose, mottled or speckled with green and white and here and there marked with dark green or brown transverse or cross lines or thickenings (septate-nodulose) between the vertical or long ribs or lines of the dorsal (back) side 89

89. Spikes crowded and dense in a more or less uninterrupted ovoid or cylindric head, 1-4 cm. long, the spikes all touching or with little space between the lowest spike and the others; perigynia pale brown or drab; beak of perigynium $1/4-1/3$ the length of the ovate or suborbicular body of the perigynium; culms rough and minutely toothed on the angles 11. *C. GRAVIDA*
89. Spikes in a more elongated interrupted cylindrical inflorescence, 2.5-15 cm. long, at least the lower spikes distant and well-separated from the others, or, if all spikes close together, then the culms usually smooth on the angles; perigynia green; beak of perigynium $1/3-1/2$ the length of the ovate body of the perigynium 90
90. Inflorescence 2-10 cm. long, the lower spikes of inflorescence usually distant and well-separated, sometimes as much as 2-3 cm. from those above; summit of inner thinner side of leaf-sheaths with a truncate (as if cut straight across) edge, the inner thinner side of lower leaf-sheaths usually cross-wrinkled and delicate; flowering culms minutely toothed on angles; leaf-blades 4.5-10 mm. long; stigmas short and stout 13. *C. SPARGANIOIDES*
90. Inflorescence 2-5 cm. long, all the spikes close together; summit of inner thinner side of leaf-sheaths with a concave or sunken center, the inner side of the lower leaf-sheaths usually firm and not cross-wrinkled; flowering culms smooth on the angles; leaf-blades 3-6 mm. wide; stigmas long and slender 12. *C. AGGREGATA*
88. Leaf-sheaths tight, closely enveloping the culms, not marked with dark green or brown transverse or cross lines or thickenings (septate-nodulose) between the vertical or long ribs or lines of the dorsal (back) side 91
91. Inflorescence a dense, more or less solid, single, unbranched, head-like mass of spikes, mostly 4-25 mm. long, usually without any interrupted areas or spaces between the spikes 92
92. Perigynia widest at the broadly rounded or truncate (as if cut straight across) base; scales of pistillate flowers short-pointed; leaf-sheaths not thickened at summit 8. *C. LEAVENWORTHII*
92. Perigynia widest near or below the middle, more or less tapering to the base; scales of pistillate flowers long-pointed or awned; leaf-sheaths thickened at summit 93
93. Perigynia 1.5-1.9 mm. wide, 2-3.3 mm. long; scales much shorter than the bodies of the perigynia and mostly concealed by the perigynia. 7a. *C. CEPHALOPHORA*
var. *CEPHALOPHORA*
93. Perigynia 2-2.5 mm. wide, 3-3.5 mm. long; scales longer than to slightly shorter than the bodies of the perigynia, the body of the scale nearly or quite as long as the body of the perigynium. 7b. *C. CEPHALOPHORA* var. *MESOCHOREA*
91. Inflorescence more elongated and more interrupted, varying from linear-oblong to oblong, or cylindric to narrowly ovoid, mostly 15-100 mm. long, usually with interrupted areas or spaces between the spikes 94
94. Inner (thinner) side of leaf-sheath usually cross-wrinkled, at least in the mature stage of growth; perigynia 1.7-3.5 mm. long; inflorescence compound, with 2 or more spikes placed on at least the lowest lateral (side) branch from the main axis (the lateral branches are often closely pressed against the main axis, making it necessary to examine them carefully) 95
95. Known only from swampy areas of southeastern Missouri; perigynia 2.5-3 mm. wide, suborbicular (nearly round) to reniform (kidney-shaped) 16. *C. TRIANGULARIS*
95. Throughout Missouri; perigynia 1-2.4 mm. wide, usually longer than broad, ovate to broadly ovate-lanceolate 96
96. Beak of perigynium about equaling main body of perigynium; perigynium 1-1.8 mm. wide; leaves usually longer than the flowering or fruiting culms 14. *C. VULPINOIDEA*
96. Beak of perigynium much shorter than the main body of perigynium; perigynium 1.5-2.4 mm. wide; leaves usually shorter than the flowering or fruiting culms 15. *C. ANNECTENS* and var. *XANTHOCARPA*
94. Leaf-sheath usually not cross-wrinkled; perigynia 3-4.5 mm. long; inflorescence simple, all the spikes arising directly from the main axis (rachis) with 1 spike at each node of the axis, not on any lateral (side) branches from the axis. 97
97. Perigynia 3-3.5 (-4) mm. long, 2-2.5 mm. wide, usually spreading at maturity; scales shorter or equal to and narrower than the main body of the perigynium, short-awned or pointed; bracts of inflorescence narrow at the base, not broadly dilated 10. *C. MUHLENBERGII*
97. Perigynia 3.5-4.5 mm. long, 2.5-3 mm. wide, mostly ascending at maturity; at least the lower scales longer and broader than the perigynia, long-awned; bracts of inflorescence broad and dilated at the base 10c. *C. MUHLENBERGII* var. *AUSTRALIS*

78. Staminate (male) flowers located at the base of some or all of the spikes (where stamens have fallen or disappeared from mature or old spikes, the location of the staminate flowers may usually be detected by the empty or closely overlapping or bunched scales at the base of the individual spikes) 98
98. Spikes 15–25 mm. long, fusiform and narrowed at both ends, 3–4 times as long as wide; perigynia 6.5–10 mm. long, lanceolate 24. *C. MUSKINGUMENSIS*
98. Without the above combination; spikes either shorter or, if as long, of a different shape; perigynia either shorter and/or of a different shape 99
99. Perigynia lanceolate or ovate-lanceolate, 3–4 times as long as wide 100
100. Sterile leafy culms abundant and strongly developed with spreading leaf-blades, these not clustered at the tip; main leaf-blades 2.5–8 mm. wide; mature perigynia 1–1.5 mm. wide, the wing rather abruptly narrowed just below the middle part; leaf-sheaths loose 101
101. Perigynia erect with strongly ascending, closely appressed tips; spikes crowded and overlapping 26. *C. TRIBULOIDES*
101. Perigynia with spreading, slightly recurved, or loosely ascending tips, not closely appressed to one another; spikes scattered and separated in an elongated inflorescence 27. *C. PROJECTA*
100. Sterile leafy culms few with ascending leafblades clustered at the tip; main leaf-blades 1–3 mm. wide; mature perigynia 1.2–2.6 mm. wide, the wing continuous to the base; leaf-sheaths closely enveloping the culms 25. *C. SCOPARIA*
99. Perigynia ovate or obovate or suborbicular, nearly as broad as long or, when longer than broad, then $1\frac{1}{4}$ – $2\frac{1}{2}$ times as long as wide 102
102. Tips of mature perigynia widely spreading or recurved; spikes globose (ball-shaped), usually crowded; sterile leafy culms abundant and strongly developed with spreading leaf-blades, these not clustered at the tip; main leaf-blades 3–7 mm. wide; leaf-sheaths loose; wing of perigynium abruptly narrowed below the middle 28. *C. CRISTATELLA*
102. Without the above combination of characters 103
103. Mature perigynia less than 2 mm. wide and mostly less than 4 mm. long 104
104. Main body of perigynium broadest in the upper half or toward the summit, nearly orbicular (rounded) to broadly obovate 32. *C. ALBOLUTESCENS*
104. Main body of perigynium broadest in the lower half at the base or near the middle, not obovate 105
105. Sterile leafy culms present and frequent with leaves clustered at summit; principal leaf-blades 4–7, mainly 3.5–6.5 mm. (rarely 2) wide; leaf-sheaths loosely enveloping the culms; spikes mostly close together and crowded (except scattered and distant in *f. perlonga*) 29. *C. NORMALIS*
105. No sterile leafy culms present; principal leaf-blades 3–5, mainly 0.5–3.5 mm. wide; leaf-sheaths tight, closely enveloping the culms; spikes mostly scattered and distant or well-separated from one another 106
106. Body of perigynium suborbicular (nearly round), rounded above and rather abruptly continuing into the beak, usually $\frac{3}{4}$ as wide as long or nearly as wide as long; spikes conspicuously tapering at the base, 6–10 mm. long; leaf-blades up to 3.5 mm. wide; inflorescence arching to nearly straight, but not nodding 31. *C. FESTUCEA*
106. Body of perigynium narrowly ovate, gradually tapering into the beak, about $\frac{1}{2}$ as wide as long; spikes mostly rounded or slightly tapering at the base, 4–8 mm. long; leaf-blades up to 2.5 mm. wide; inflorescence usually nodding from above the lowest spike 30. *C. TENERA*
103. Mature perigynia more than 2 mm. wide and usually more than 4 mm. long (sometimes only 3.5 mm. long) 107
107. Main body of perigynium broadest in the upper half or toward the summit, broadly obovate to nearly orbicular 108
108. Plants of sink-hole ponds, and of swamps in southeastern Missouri, forming large dense clumps; scales of pistillate flowers with a slender or short birstle-like tip; perigynia 2.5–4 mm. wide; achenes constricted to a slender stalk-like base; leaf-blades 2.5–5.5 mm. wide 37. *C. ALATA*

442 *Scleria verticillata*

443 *Carex praegracilis*

444 *Carex Douglasii*

108. Plants of other habitats, forming small tufts or clumps; scales of pistillate flowers short- to slender-pointed (acute to acuminate); perigynia 1.5-2.5 (-3.5) mm. wide; achenes without a constricted stalk-like base or with a slight stalked base; leaf-blades 2-3.5 (-4) mm. wide 109
109. Perigynia pale green to dull brown, nerved on both faces, 1.5-2.5 mm. wide; scales of pistillate flowers pale, whitish or white with green. 32. *C. ALBOLUTESCENS*
109. Perigynia brown, or brown and green, not nerved on the inner (ventral) face or rarely faintly nerved, 2.5-3.5 mm. wide; scales of pistillate flowers usually rusty- or yellow-brown with green midnerve 34. *C. BREVIOR*
107. Main body of perigynium broadest in the lower half at the base or near the middle, not obovate 110
110. Mature perigynia with erect or appressed tip 111
111. Spikes rounded or obtuse at summit 34. *C. BREVIOR*
111. Spikes tapering to a rather pointed summit 112
112. Plants of swampy limey meadows and at the base of wet limestone bluffs along creeks, only in the Ozark section; heads tawny or rusty-brown; perigynia of firm texture, obviously thicker than their scales and well expanded across and covering the achene, the achene not showing its impression, the inner face of the perigynium nerveless or only faintly nerved 33. *C. SUBERECTA*
112. Plants of prairies and meadows and other open habitats, throughout Missouri; heads straw-colored to yellow-brown; perigynia of very thin texture, of about the same as that of their scales, only barely stretched over the achene within, the achene easily showing its outline, the inner face of the perigynium finely nerved 25. *C. SCOPARIA*
110. Mature perigynia with spreading or ascending loose or free tips 113
113. Mature perigynium flat, thin and nearly transparent, mainly 5.5-7.5 mm. long, 2.7-4.8 mm. wide, buff- or straw-colored, nerved on both faces; pistillate scales pale brown or straw-colored 36. *C. BICKNELLII*
113. Without the above combination of characters; mature perigynia usually plano-convex (one side flat, the other side convex or slightly raised in the middle), thicker, firmer, subcoriaceous (leathery or hard), not transparent, pale green, brown, or green and brown; pistillate scales pale brown, yellow-brown with green, or gray-green 114
114. Scales of pistillate flowers tipped with a long point or awn; leaf-sheaths green, strongly nerved on the thinner inner (ventral) side nearly to the summit; plants of sink-hole ponds in the Ozark section 38. *C. STRAMINEA*
114. Scales of pistillate flowers short- or slender-pointed or blunt, not awned; leaf-sheaths mostly white and transparent on the thinner inner (ventral) side; plants found throughout Missouri in prairie swales, along railroad tracks, meadows, and other open habitats 115
115. Inflorescence mostly compact, of crowded, pale green, whitish-green, or drab spikes; spikes broadly rounded at top and bottom; perigynia nerved on both sides, more gradually tapering with a long slope from the body into the relatively longer beak; scales of pistillate flowers rather blunt or dull-pointed, reaching only to base of the beak of perigynium 35. *C. MOLESTA*
115. Inflorescence of a more elongated type with the spikes more separated from one another, brown or brown and green; spikes usually more narrowed or tapering at the bottom, conic to slightly rounded at the top; perigynium

445 *Carex Sartwellii*446 • *Carex retroflexa* var. *retroflexa*
446 □ *Carex retroflexa* var. *texensis*447 *Carex convoluta*

nerveless or nearly so on the inner (ventral) face, more abruptly changing from the rounded upper side of the body on a shorter slope into the relatively shorter beak; scales of pistillate flowers usually slender-pointed (acuminate) and almost as long as the beak of perigynium 34. *C. BREVIOR*

The following sequence of species indicates the sections or species-groups to which they belong, and the arrangement follows essentially that of Mackenzie (*North American Flora* 18: 1-478. 1931-35).

Subgenus I. **Vigneae**

Section 1. **Divisae**

1. ***Carex praegracilis*** W. Boott
Flowers June-July.

Map 443

Occurs in dry open ground and along railroads. Known only from St. Louis (right-of-way of the Manufacturers' Railway, Arsenal Street, St. Louis, on the banks of the Mississippi River, June 7, 1959, *Muehlenbach 1522*) and Jackson (Sheffield, *Bush 4798*) counties.

Ranges from Manitoba, Michigan, Iowa, Missouri, and Oklahoma, west to Yukon and California and south to northern Mexico.

2. ***Carex Douglasii*** Boott
Flowers early May-late June.

Map 444

Occurs along railroad tracks in St. Louis County, where collected several times at the Carrie Avenue Freight Yard in St. Louis by Dr. Victor Muehlenbach (May 8, 1955, *Muehlenbach 571*; June 24, 1956, *Muehlenbach 971*; June 1, 1957, *Muehlenbach 1178*).

Ranges from Missouri, Iowa, and Manitoba, west to British Columbia and south to Colorado and California.

Section 2. **Intermediae**

(included under section *Arenariae* in *Gray's Manual*)

3. ***Carex Sartwellii*** Dewey
Flowers June-July.

Map 445

Known only from low meadows in Jackson County, western Missouri.

Ranges from Quebec to British Columbia, south to New York, Ohio, Indiana, Illinois, Missouri, Nebraska, and Colorado.

Section 3. **Bracteosae**

4. ***Carex retroflexa*** Muhl.

Map 446

The species occurs in two varieties as indicated above in the key to species.

Flowers late April-June.

Frequents dry open, rocky, or sandy woods, wooded sandstone ledges of bluffs, cherty slopes, rich ravine slopes, wooded valleys, and rarely in grassy open places. Most frequently in acid soils. Throughout the Ozark section and locally northeast in northern

- 4a. ***Carex retroflexa*** var. ***retroflexa***
Carex retroflexa Muhl. [G, P & S]

Map 446

448 *Carex rosea*449 • *Carex cephalophora* var. *cephalophora*
449 □ *Carex cephalophora* var. *mesochorea*450 *Carex Leavenworthii*

Missouri in Monroe, Shelby, and Schuyler counties.

Ranges from Florida to Texas, north to New Hampshire, Vermont, New York, Ohio, Michigan, Illinois, Missouri, and Kansas.

4b. ***Carex retroflexa* var. *texensis*** (Torr.)

Fern. Map 446

Carex texensis (Torr.) Bailey [G, P & S]

Flowers May–June.

Known only from the southeastern lowland section in Dunklin County (wet places, May 24, 1893, *Eggert*). A collection from Cape Girardeau County, previously identified as *C. texensis*, is now placed in *C. convoluta*.

Ranges from Georgia to Texas, north to New Jersey, Maryland, Ohio, Kentucky, and southeastern Missouri.

The small differences separating the two variations appear to justify their being maintained as varieties rather than as species.

5. ***Carex convoluta*** Mackenz.

Map 447

Flowers mid-May–late June.

Frequents rich wooded ravines, slopes, and valleys. Throughout Missouri, but not recorded from some sections.

Ranges from Nova Scotia to Manitoba, south to South Carolina, Alabama, Arkansas, and Kansas.

6. ***Carex rosea*** Schkuhr

Map 448

Flowers April–July.

Frequents rich wooded ravines, slopes, and valleys. Throughout Missouri, but not recorded from some sections.

Ranges from Nova Scotia and Quebec to North Dakota, south to Georgia, Alabama, and Louisiana.

Except for the chief difference in the styles, this species cannot be readily distinguished from *C. convoluta*, and by Gleason (*New Illustrated Flora* 1: 309, 1952) the two are united, along with *C. radiata*, under

C. rosea. In the present work the two species are being retained as separate, pending further observations and experimental evidence on the significance of straight versus twisted styles.

7. ***Carex cephalophora*** Muhl.

Map 449

The species is represented in Missouri, by two varieties, as indicated in the key to species.

7a. ***Carex cephalophora* var. *cephalophora***

Map 449

Carex cephalophora Muhl. [G, P & S]

Flowers May–August.

Frequents dry or rocky wooded slopes, ridges, uplands, and openings of woods, mostly in cherty or sandy soils, pastured fields, and rarely at the base of bluffs along stream banks. Most frequently in acid soils. Throughout Missouri.

Ranges from Florida to Texas, north to Maine, Quebec, Ontario, Michigan, and Manitoba.

7b. ***Carex cephalophora* var. *mesochorea***

(Mackenz.) Gl.

Map 449

Carex mesochorea Mackenz. [G, P & S]

Flowers May–August.

Occurs in dry upland prairies, pastured fields, openings on dry chert or limestone wooded slopes, open fields, and rocky open valleys. Scattered in southern and central Missouri north to Pike, Boone, and Caldwell counties.

Ranges from Massachusetts to Wisconsin, south to Virginia, Tennessee, Missouri, and Texas.

Separated from var. *cephalophora* only by the larger perigynia, generally taller culms, and coarser habit of growth.

8. ***Carex Leavenworthii*** Dew.

Map 450

Carex cephalophora var. *angustifolia* Boott [Shinners]

Flowers April–June.

451 *Carex arkansana*452 • *Carex Muhlenbergii* var. *Muhlenbergii*
452 □ *Carex Muhlenbergii* var. *enervis*
452 x *Carex Muhlenbergii* var. *australis*453 • *Carex gravida* var. *gravida* f. *gravida*
453 x *Carex gravida* var. *gravida* f. *laxifolia*
453 □ *Carex gravida* var. *Lunelliana*

Occurs in a variety of situations, from rich and low wet woodland, wet wooded valleys, along streams, and alluvial open ground in valleys, to prairie swales, wet meadows in open valleys, and open or dry woods and ridges in cherty, sandstone, limestone, or granitic soils. Throughout Missouri.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Ontario, Michigan, Illinois, Iowa, and Kansas.

This species is easily distinguished from the two varieties of *C. cephalophora* above by the broad-based perigynia. Both varieties of *C. cephalophora* and *C. Leavenworthii* have a small congested usually single head of spikes.

9. ***Carex arkansana* Bailey**

Map 451

Flowers May–June.

Occurs in wet river bottom prairies, prairie swales, and openings in oak woods. Rare, known only in western Missouri in Linn, Livingston, Bates, and Jasper counties. In the wet bottom prairies of the Grand River and tributaries in Linn and Livingston counties this species reaches its northeastern known limits of geographical distribution.

Ranges from northeastern Texas to western Arkansas northeast to western Missouri.

This species is readily recognized by the very long leafy bracts of the inflorescence, being much longer than in any other species of this group.

10. ***Carex Muhlenbergii* Schk.**

Map 452

Missouri material is represented by three varieties:

a. Perigynia strongly nerved on both faces . . .

10a. *C. MUHLENBERGII* var. *MUHLENBERGII*

a. Perigynia nerveless on the inner (ventral) face

or with only short nerves at the base . . . b

b. Perigynia 3–3.5 mm. long, 2–2.5 mm. wide, usually spreading at maturity; scales shorter or equal to and narrower than the main body of the perigynia, short-awned or pointed; bracts of inflorescence narrow at the base, not broadly dilated . . .

10b. *C. MUHLENBERGII* var. *ENERVIS*

b. Perigynia 3.5–4.5 mm. long, 2.5–3 mm. wide, mostly ascending at maturity; at least the lower scales longer and broader than the perigynia, long-awned; bracts of inflorescence broad and dilated at the base

10c. *C. MUHLENBERGII* var. *AUSTRALIS*

10a. ***Carex Muhlenbergii* var. *Muhlenbergii***

Map 452

Carex Muhlenbergii Schk. [G, P & S]

Flowers mid-May–July.

Frequents usually dry rocky or open woods, usually in acid soils of chert, sandstone, or granite, but also in limestone areas; also in sandy open ground, along railroads, and occasionally in rich woods or low wet woodland. Throughout Missouri, less common than var. *enervis*, into which it overlaps.

Ranges from Florida to Texas, north to Maine, Quebec, Ontario, Ohio, Michigan, Wisconsin, and Minnesota.

10b. ***Carex Muhlenbergii* var. *enervis* Boott**

Map 452

Flowers mid-May–June.

Frequents the same habitats as var. *Muhlenbergii*, but commoner in the state.

Ranges from Florida to Texas, north to Maine, Ontario, Michigan, Illinois, Iowa, and Nebraska.

10
PLATE NO. 84

11

454 *Carex aggregata*455 *Carex sparganioides*456 *Carex vulpinoidea* (Fox Sedge)

10c. ***Carex Muhlenbergii* var. *australis*** Olney
Map 452

Carex austrina (Small) Mackenz. [G, P & S]

Carex Muhlenbergii var. *austrina* Small

Flowers late April–July.

Occurs in dry upland woods, openings on dry chert or limestone wooded slopes, but mostly in dry upland, cherty limestone glades, sandy prairies, roadside open banks, and railroads. Mostly in western and southern Missouri.

Ranges from Arkansas and Texas, north to Missouri and Kansas.

Intergrading plants between var. *australis* and var. *Muhlenbergii* and var. *enervis* would appear to justify treating var. *australis* as a well-marked variety rather than as a species.

11. ***Carex grvida*** Bailey Map 453

Missouri material is represented by 3 variations:

- a. Perigynia ovate, 2–3 mm. wide, gradually tapering into a beak about 1 mm. long, faintly nerved or without nerves on the outer lower (dorsal) face; scales of pistillate flowers mostly with long awns or long slender points . . . b

b. Inflorescence 1–3 cm. long . . . 11a. *C. GRAVIDA*
var. *GRAVIDA* f. *GRAVIDA*

b. Inflorescence 3–5 cm. long . . . 11b. *C. GRAVIDA*
var. *GRAVIDA* f. *LAXIFOLIA*

- a. Perigynia broadly ovate to suborbicular, up to 3.8 mm. wide, abruptly passing into a shorter beak about 0.5 mm. long, usually more strongly and definitely nerved on the outer lower (dorsal) face; scales of pistillate flowers usually only short slender-pointed (acuminate) or short-awned

11c. *C. GRAVIDA* var. *LUNELLIANA*

11a. ***Carex grvida* var. *grvida* f. *grvida***

Map 453

Carex grvida Bailey [G, P & S]

Flowers early May–July.

Occurs in prairie swales, dry open banks, and open places in wooded sections. Scattered in northern, western, and central Missouri; apparently absent from most of the Ozark section.

Ranges from Ontario and North Dakota to Wyoming, south to Ohio, Indiana, Illinois, Missouri, and Kansas.

11b. ***Carex grvida* var. *grvida* f. *laxifolia***

(Bailey) Kükenth.

Map 453

Carex grvida f. *laxifolia* [G]

Known only from a single collection in Greene County (Palmer 62263).

11c. ***Carex grvida* var. *Lunelliana*** (Mackenz.)

Herm.

Map 453

Carex Lunelliana Mackenz. [P & S]

Flowers May–June.

More common in Missouri than var. *grvida*, occurring in dry upland prairies and prairie openings, open grassy slopes and pastures, and less commonly in rich wooded slopes or wooded valleys. Scattered in northern, central, and western Missouri; apparently absent from the Ozark and southeastern lowland sections of the state.

Ranges from Indiana, Michigan, Illinois, Iowa, and Kansas, south to Arkansas, Oklahoma, Texas, and New Mexico.

12. ***Carex aggregata*** Mackenz.

Map 454

Carex sparganioides Muhl. var. *aggregata* (Mackenz.) Gl. [BB]

Carex cephaloidea [of P & S], not Dewey

Flowers early May–early June.

Frequents wooded valleys, rich wooded slopes and ravines, low wet woodland, along streams, alluvial thickets and fields, and in wet river bottom prairies. Scattered over the state.

Ranges from New York to Iowa, south to D. C., Kentucky, Missouri, and Oklahoma.

457 • *Carex annectens* var. *annectens*
457 • *Carex annectens* var. *xanthocarpa*

458 *Carex triangularis*

459 *Carex decomposita*

The status of this as a species distinct from *C. sparganioides* is doubtful. In their extremes the two can be readily distinguished. But some plants (such as *Palmer 59972* from Christian County and *Palmer 59577* and *Palmer 60085* from McDonald County) may show certain characters of *C. sparganioides* (inner ventral side of leaf-sheaths prominently cross-wrinkled) and other characters of *C. aggregata* (leaf-blades 3–6 mm. wide, concave summit of firm inner band of leaf-sheath). Additional collections may show other types of intergradation, casting considerable doubt as to the validity of *C. aggregata* as a true species. Pending further and more detailed studies of plants so identified, *C. aggregata* is being retained in the specific category.

Some specimens from St. Louis and Jackson counties, previously erroneously placed under *C. cephaloidea* in *Palmer and Steyermark's Annotated Catalogue*, are now referred to *C. aggregata*.

13. ***Carex sparganioides* Muhl.** Map 455
Carex sparganioides var. *sparganioides* [BB]
Flowers late April–July.
Usually found in rich woodland of valleys, ravines,

slopes (especially north-facing limestone or sandstone), moss-covered boulders, more rarely in river bottom prairie or wet open valleys. Throughout Missouri, but apparently absent from the southeastern lowland section.

Ranges from New Hampshire and Quebec to Ontario, Minnesota, and South Dakota, south to Virginia, Tennessee, Missouri, and Kansas.

Usually abundantly distinct in its relatively broad leaf-blades, well-separated lower spikes of the elongated inflorescence, and other characters indicated in the key, but, as stated above under *C. aggregata*, intergrading and overlapping specimens are found, making it sometimes difficult to place collections with absolute certainty.

The perigynia in this species vary from 3–4.5 mm. long. The pistillate scales are usually acuminate both in this species and in *C. aggregata*. Although separated vegetatively from *C. Muhlenbergii* var. *Muhlenbergii* and var. *enervis* by the loose leaf-sheaths which are conspicuously mottled and cross-marked on the back side, the perigynia of *C. sparganioides* are longer (3–4.5 mm. as contrasted with 3–3.5) with longer beaks than those of *C. Muhlenbergii* var. *Muhlenbergii* and var. *enervis*.

Section 4. **Multiflorae**

14. ***Carex vulpinoidea* Michx.** Fox Sedge Map 456
Flowers May–July.

Frequents prairie swales, wet river bottom prairies, wet open valleys, margins of ponds, streams, and spring branches, limy open or wooded swamps, and low wet woods. Throughout Missouri, and one of the most abundant species in the state.

Ranges from Newfoundland to British Columbia, south to Florida, Texas, Arizona, and Oregon.

Although many plants show the typical cross-wrinkled inner (ventral) side of the leaf-sheath, other

plants may exhibit only a purple-red-dotted leaf-sheath. Although the bracts of the inflorescence are usually bristlelike or setaceous, the lowest one is sometimes rather leaflike (foliaceous) rather than setaceous.

15. ***Carex annectens* Bickn.** Map 457
Two varieties are usually distinguished:

Perigynia 1.7–2.4 mm. wide, mostly more than 2 mm. wide, usually clearly nerved on the outer lower (dorsal) side, and with a rather conspicuous beak. . . . 15a. *C. ANNECTENS* var. *ANNECTENS*

460 *Carex oklahomensis*461 • *Carex stipata* var. *stipata*
461 □ *Carex stipata* var. *maxima*462 *Carex laevivaginata*

Perigynia 1.4–1.8 mm. wide, mostly less than 2 mm. wide, without nerves or only faintly nerved on the outer lower (dorsal) side, and with a very small beak. 15b. *C. ANNECTENS* var. *XANTHOCARPA*

15a. ***Carex annectens* var. *annectens*** Map 457
Carex annectens Bickn. [G, P & S in part]

Occurs in dry and wet prairies, open wet ground in valleys, borders of sink-hole or other ponds, and swampy limey meadows.

Less common in Missouri than var. *xanthocarpa*.

Ranges from Maine to Wisconsin, south to Florida and Texas.

15b. ***Carex annectens* var. *xanthocarpa*** (Bickn.) Wieg. Map 457

Carex annectens [of P & S in part], not Bickn.
Carex brachyglossa Mackenz.

Frequents the same situations as var. *annectens*, but the commoner variety in Missouri.

Ranges from Maine and Quebec to Wisconsin and Iowa, south to Virginia, Ohio, Illinois, Missouri, and Kansas.

Most of the material encountered in Missouri pertains to var. *xanthocarpa*, which intergrades freely with var. *annectens*. The two varieties are not separated on the distribution map. The perigynia of *C. annectens* are appressed-ascending in the spikes, whereas in *C. vulpinoidea* and *C. triangularis*, they spread out widely at maturity.

16. ***Carex triangularis*** Boeckl. Map 458

Flowers early May–June.

Known only from swamps and swampy ground in southeastern Missouri from Wayne (swamps, May 12, June 5, 1893, Williamsville, *Eggert*) and Dunklin (May 17, 1892, *Bush*) counties.

Ranges from Mississippi to Texas, north to southeastern Missouri and Oklahoma.

Section 5. **Paniculatae**

17. ***Carex decomposita*** Muhl. Map 459
Flowers late April–July.

Known only from sink-hole ponds in the southeastern Ozarks and in the lowland swamps of Dunklin County, southeastern Missouri.

Ranges from Florida to Louisiana, north to Virginia, New York, Ohio, Indiana, Michigan, and Missouri.

A very distinct species, found in greatest abundance in the natural sink-hole ponds in the upland oak-

hickory woods of the southeastern Ozarks, where it is associated with *C. alata*, *C. comosa*, *C. lupulina*, and *C. tribuloides*. Like *C. alata* and *C. comosa*, it forms dense large tussocks or leafy mounds in the water. Its distinctive habitat and habit, together with its compound inflorescence of elongated thick lower branches, and thick swollen perigynia broadest in the upper half, readily prevent this species from being confused with other sedges.

PLATE NO. 85

463 *Carex crus-corvi*464 *Carex conjuncta*465 *Carex interior*Section 6. **Vulpinae**

18. ***Carex oklahomensis*** Mackenz. Map 460
Carex stipata var. *oklahomensis* (Mackenz.) Gl. [BB]
 Flowers May–July.

Occurs in low river bottom prairies, wet places in upland prairies, swampy open meadows around upland ponds, wet sandy ground bordering sloughs and streams, and swales in low open woods. Known only from Laclede, Christian (*Palmer 59918*), Jasper (*Palmer 1962, 2174, 2442, and 25299*), and Newton (*Palmer 54200*) counties of southwestern Missouri.

Ranges from southwest Missouri and Arkansas, south to Oklahoma and Texas.

Some Missouri material previously referred to this species has been found to be erroneously identified, and is now referred to *C. stipata* var. *stipata* and *C. conjuncta*.

19. ***Carex stipata*** Muhl. Map 461
 Two varieties may be recognized in Missouri:

Perigynia 4–5 mm. long, the beak about equaling the length of the main body; leaf-blades 4–8 mm. wide 19a. *C. STIPATA* var. *STIPATA*

Perigynia 5–6 mm. long, the beak longer than the main body; leaf-blades 8–17 mm. wide 19b. *C. STIPATA* var. *MAXIMA*

- 19a. ***Carex stipata*** var. *stipata* Map 461
Carex stipata Muhl. [G, P & S]
 Flowers May–July.

Occurs along streams, spring branches, wet river bottom prairies, wet open ground in valleys, and low wet woods. Scattered throughout the state.

Ranges from Labrador to Alaska, south to North Carolina, Tennessee, Missouri, Kansas, New Mexico, and California.

- 19b. ***Carex stipata*** var. *maxima* Chapm. Map 461

Carex uberior (Mohr) Mackenz.

Occurs in wet low ground in eastern Missouri, where known from St. Louis (Allenton, July 30, 1900, *Letterman*) and Shelby (open alluvial meadow along east side of Tiger Fork, 1½ mi. north of Burksville, June 5, 1951, *Steyermark 71719*) counties.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Indiana, and Missouri.

The two varieties intergrade and are not separated on the distribution map of the species.

20. ***Carex laevivaginata*** (Kükenth.) Mackenz. Map 462

Flowers May–June.

Occurs in swampy meadows along valleys of small streams and in low wet woods in the southeastern quarter of the state.

Ranges from Maine to Minnesota, south to Florida, Alabama, and Missouri.

21. ***Carex crus-corvi*** Shuttlw. Map 463
 Flowers late May–July.

Occurs in wooded swamps and swales, and alluvial wooded flood plains, where especially common along the Mississippi and Missouri rivers and other large streams tributary to those waters; also in wet river bottom prairies. Mainly found in eastern and central Missouri, and in the western part of the state mostly south of the Missouri River; absent from northwestern Missouri and most of the Ozark section.

The foliage of *C. crus-corvi* varies from glaucous (gray-green or bluish green) to deep green. The species is easily recognized by the compound much-

8
PLATE NO. 86

466 *Carex muskingumensis*467 • *Carex scoparia* var. *scoparia* f. *scoparia*
467 □ *Carex scoparia* var. *scoparia* f. *moniliformis*468 *Carex tribuloides*

branched inflorescence with elongated lower branches, the whole up to 25 cm. long and 6 cm. thick, and by the very elongated beak of the perigynium.

22. ***Carex conjuncta*** Boott Map 464
Flowers early May-late June.
Occurs in wet river bottom prairies, prairie swales, wet open valleys, alluvial thickets, along streams, but

most commonly in low wet, alluvial, or rich woods. Common in northern, central, and western Missouri; apparently rare or absent in most sections of the Ozarks and altogether absent from the southeastern lowland section.

Ranges from New York to South Dakota, south to Virginia, Tennessee, Missouri, and Kansas.

Section 7. **Stellulatae**

23. ***Carex interior*** Bailey Map 465
Flowers early April-June.
Frequents swampy, calcareous, spring-fed meadows and occasionally found on dripping limestone ledges at the base of bluffs. Mainly in the southeastern Ozark section and locally west in Camden and Douglas counties.
Ranges from Labrador to British Columbia, south to Delaware, Pennsylvania, West Virginia, Ohio, Indiana, Illinois, Missouri, Kansas, New Mexico, California, and northern Mexico.

This well-marked species of *Carex* with very narrow leaf-blades (1-3 mm. wide) and few-flowered small clusters of widely spreading or recurving perigynia is a characteristic inhabitant of swampy, spring-fed, calcareous meadows, where it is associated with *C. leptalea*, *C. suberecta*, and *C. stricta*.

It is another one of the boreal North American species at one of its southern limits in the swampy calcareous meadows of the Ozarks, where it probably represents a relict survivor of an Ice Age (Pleistocene) flora.

Section 8. **Ovales**

24. ***Carex muskingumensis*** Schwein. Map 466
Flowers late May-October.
Frequents wooded swamps and alluvial flood plain woods of the Mississippi River in eastern Missouri and of other large streams (Fabius, Wyaconda, Salt, Chariton, Locust, Grand, Thompson, South Grand, and Marais des Cygnes) of northern and west-central Missouri. Absent from the Ozark region, southeastern lowland, and most of the unglaciated prairie sections.
Ranges from Ontario to Manitoba, south to Kentucky, Missouri, and Kansas.
This well-marked species is easily recognized by the narrowly elliptical, long and pointed, pale brown

spikes containing long, narrow, thin perigynia, together with the numerous leafy sterile shoots with conspicuously spreading leaf-blades.

25. ***Carex scoparia*** Schkuhr Map 467
Represented in Missouri by two variations:

Spikes crowded or overlapping one another in an erect or slightly arching inflorescence . . .

25a. *C. scoparia* var. *scoparia* f. *scoparia*
All spikes, or at least the lower ones, distant from one another in a more or less stretched out, flexuous (zigzag curving) type of inflorescence

25b. *C. scoparia* var. *scoparia* f. *moniliformis*

469 *Carex projecta*

471 □ *Carex normalis* f. *perlonga*

25a. *Carex scoparia* var. *scoparia* f. *scoparia*

Map 467

Carex scoparia Schkuhr [G, BB, P & S]

Flowers late May–July.

Frequent in wet river bottom prairies, wet open valleys, prairie swales, upland prairies, margins of sink-hole ponds, and roadside ditches. Throughout Missouri, and the common variation encountered.

Ranges from Newfoundland to British Columbia, south to South Carolina, Tennessee, Arkansas, New Mexico, and Oregon.

Sometimes mistaken for *C. tribuloides*, but easily distinguished vegetatively from that species by the much narrower leaf-blades and culms, tightly fitting leaf-sheaths, and few ascending leaf-blades bunched near the top of the sterile culms; the spikes in *C. scoparia* usually taper to a point, whereas they are blunt or obtuse in *C. tribuloides*.

25b. *Carex scoparia* var. *scoparia* f.

moniliformis (Tuckerm.) Kükenth. Map 467

Carex scoparia f. *moniliformis* (Tuckerm.) Kükenth.

[G]

Carex scoparia var. *moniliformis* Tuckerm. [BB]

Represented by a single collection from southwestern Missouri in Barton County (sandy soil, upland prairie, along small stream, $\frac{1}{2}$ mi. west of Duvall, May 26, 1952, Palmer 53945).

Ranges from Newfoundland to British Columbia, south to Virginia, New York, and Missouri.

The inflorescence in this form varies from 3.5–6 cm. long, that in f. *scoparia* from 1.5–5 cm. long.

26. *Carex tribuloides* Wahlenb.

Map 468

Carex tribuloides var. *sangamonensis* Clokey

Flowers May–August.

Frequent in swampy or low wet woods of alluvial soils, borders of streams and spring branches, sink-hole and other ponds, wet river bottom prairies, wet open

valleys, and low meadows. Throughout Missouri, and one of the commonest species in the state.

Ranges from Quebec, Ontario, Michigan, Wisconsin, Minnesota, and Nebraska, south to Florida, Louisiana, and Oklahoma.

The gray-green or pale brown blunt spikes are somewhat variable in size, shape, and in the length of the perigynia, but are readily spotted by the thin and erect or appressed perigynia with the wing abruptly tapering below the middle, and by the numerous sterile culms bearing many spreading leaves.

Plants having more slender culms, narrower leaves, and narrow perigynia 3–4 mm. long have been separated as *C. tribuloides* var. *sangamonensis*, but do not appear to merit recognition. Plants answering this description are two Daniels collections from wet meadow near dam, Columbia, Boone County, July 3, 1903, and specimens from St. Louis and Jackson counties.

27. *Carex projecta* Mackenz.

Map 469

Flowers May–October.

Occurs in wet river bottom prairies, prairie swales, wet open valleys, swampy ground in bald cypress forest, and low wet woods or wooded alluvial soils of flood plain. Scattered throughout Missouri, but probably more common.

Ranges from Newfoundland to Manitoba, south to D. C., West Virginia, Ohio, Indiana, Illinois, and Missouri.

Very similar to *C. tribuloides*, from which it is mainly distinguished by the more loosely ascending to spreading tips of the perigynia and by the more usually elongated, loosely arranged, more scattered heads of the inflorescence.

28. *Carex cristatella* Britt.

Map 470

Flowers late May–July.

Frequents wet river bottom prairies, swampy

472 *Carex tenera*473 *Carex festucacea*474 *Carex albolutea*

meadows, alluvial soils in wet open valleys, thickets, borders of natural ponds, swamps, sloughs, and ditches, along spring branches, along railroads, and in rich wooded valleys. Northern and central Missouri south to Jefferson, Callaway, Johnson, and Jackson counties, and locally south in Camden Co.; absent from the Ozark region, the southeastern lowland and southwestern unglaciated prairie sections.

Ranges from Quebec to North Dakota, south to Virginia, Kentucky, Missouri, and Nebraska.

This species is usually readily identified in the field by the crowded nearly globose spikes with the perigynia widely spreading in all directions in a series of little rosettes, and, vegetatively, by the many widely spreading leaves produced from the numerous sterile culms. Some authors consider it to have probably originated as a hybrid between *C. tribuloides* and *C. Bebbii*.

29. ***Carex normalis* Mackenz.** Map 471

Represented in Missouri by two variations:

Spikes more or less crowded and usually overlapping in a rather straight or erect inflorescence 1.5–4 cm. long . . . 29a. *C. NORMALIS* f. *NORMALIS*

Most or all the spikes rather remote and separated from one another and not overlapping in a flexuous (alternately zigzag curving) arching inflorescence 3–7 cm. long . . . 29b. *C. NORMALIS* f. *PERLONGA*

29a. ***Carex normalis* f. *normalis*** Map 471

Carex normalis Mackenz. [G, BB, P & S]

Flowers early May–July.

Frequents low wet woods, wooded swamps or alluvial soils, rich wooded valleys, dry and open wooded slopes, open alluvial soils, prairie swales, low river bottom prairies, along small streams, and along railroads. Scattered over the state, but most common in northern, central, and eastern Missouri; absent from most parts of the Ozark section.

Ranges from Maine to Manitoba, south to North Carolina, Tennessee, Missouri, and Oklahoma.

29b. ***Carex normalis* f. *perlonga* Fern.** Map 471

Known from Randolph County, central Missouri. Scattered throughout the range of f. *normalis*.

30. ***Carex tenera* Dewey** Map 472

Flowers late April–June.

Occurs in upland prairies, fields, and grassy open places, wet low woods bordering ditches, occasionally in dry open woods. Scattered in Missouri, and infrequently collected.

Ranges from Quebec to Alberta, south to North Carolina, Ohio, Indiana, Illinois, Missouri, South Dakota, and Montana.

This species, with small spikes of relatively few flowers and small perigynia, has been found in less than a dozen counties of the state. Perhaps future collecting will reveal its greater abundance and frequency. The absence of sterile leafy culms in this species and in *C. festucacea* is a distinctive character separating the two species from others of the *Ovales* section in Missouri.

31. ***Carex festucacea* Schkuhr** Map 473

Flowers May–July.

Occurs in prairie swales, upland dry prairies, and low or flat wet woods. Scattered over most sections of the state, but not common.

Ranges from Massachusetts, New York, Ohio, Michigan, Illinois, and Iowa, south to Georgia, Louisiana, and Oklahoma.

Like *C. tenera*, this species, although well-marked by the small spikes of relatively small perigynia, has been collected from less than twenty counties in the state. *Carex festucacea* is very close to and difficult to distinguish from *C. tenera*, the main distinction being in the shape of the body of the perigynium, which in *C. tenera* is narrowly ovate and half as wide as long,

475 *Carex suberecta*

476 *Carex brevior*

477 *Carex molesta*

while in *C. festucacea* it is suborbicular to broadly ovate and from nearly 3/4 as wide as long to nearly as wide as long. Other differences, as given in the key, indicate additional items of divergence of these two species.

32. **Carex albolutescens** Schwein. Map 474
Carex straminea according to Mackenzie [P & S], not *C. straminea* Willd.
Flowers May–July.

Occurs in moist depressions and swales of upland prairies, low wooded swamps, open places, and along shaded banks of streams. Infrequently collected, and known from less than six counties in southern Missouri north to Henry County; future collecting should reveal a greater frequency of occurrence.

Ranges from Florida to Texas, north near the coast to Nova Scotia, and inland to Pennsylvania, Michigan, Indiana, Illinois, and Missouri.

This species is stated to hybridize with *C. tribuloides*. Its small spikes with relatively small perigynia resemble most closely those of *C. tenera* and *C. festucacea*, and sometimes may also be mistaken for plants of *C. brevior* with small spikes and short perigynia less than 4 mm. long. From these other three species it is mainly distinguished by the body of the perigynia being broadest above the summit of the achene in the upper third and by the nerved inner face of the perigynium.

33. **Carex suberecta** (Olney) Britt. Map 475
Flowers late April–August.

Frequents calcareous (limy), spring-fed, swampy meadows and moist limestone ledges along small creeks in the eastern Ozark section west to Miller, Camden, Texas, and Howell counties.

Ranges from Ontario to Minnesota, south to Virginia, Ohio, Indiana, Illinois, and Missouri.

A characteristic sedge of spring-fed, calcareous, swampy meadows, where it is associated with *C. leptalea*, *C. stricta*, and *C. interior*, and other calciphiles.

In most parts of its range, *C. suberecta* is a species of glaciated terrain, but in Missouri it is in strictly unglaciated stations, and is probably a relict survivor of a more boreal flora that took refuge or migrated southward during one of the advances of the recent Ice Age (Pleistocene). The habitat and rather pointed, somewhat crowded, rusty-brown or tawny spikes, with closely appressed perigynia, should help identify this species in the field.

34. **Carex brevior** (Dew.) Mackenz. Map 476
Flowers May–June.

Most frequent in dry upland prairies and prairie swales along railroads, open grassy slopes and prairie openings, wet river bottom prairies, and wet open valleys. Mostly absent from the Ozark section, but elsewhere common, especially in northern, central, and western Missouri.

Ranges from Maine to British Columbia, south to D. C., Tennessee, Arkansas, Texas, New Mexico, and Oregon.

Somewhat variable in the shape and size of the perigynia, which vary from broadly ovate to suborbicular, and 3.5–5.5 mm. long by 2.5–3.5 mm. broad. Spikes with short perigynia less than 4 mm. long are distinguished from *C. festucacea* by having the beak of the perigynia less than half the length of the body instead of as in *C. festucacea* half or more the length of the body, and the perigynia more than 2 mm. wide, while from *C. tenera* such plants may be distinguished by the broader perigynia and the suborbicular instead of narrowly ovate body of the perigynia.

35. **Carex molesta** Mackenz. Map 477
Flowers May–early July.

Usually found in dry or wet prairies of upland or river bottom, open thickets in valleys, pastures, grassy slopes, and dry open woodland or low wooded alluvial soils of flood plain. Throughout Missouri, except not recorded in the southeastern lowland section.

478 *Carex Bicknellii*479 *Carex alata*480 *Carex straminea*

Ranges from Massachusetts and Vermont to Saskatchewan, south to D. C., Tennessee, Arkansas, Kansas, and Colorado.

Sometimes mistaken for *C. brevior*, from which it is mainly distinguished by the gray-green or pale green spikes rounded at both ends, the perigynia nerved on both faces, shorter, blunter pistillate scales, and the more gradually tapering beak of the perigynia. Specimens of *C. molesta* are sometimes confused with *C. Bicknellii* having ovoid heads rounded at the base, but may be distinguished by the relatively shorter as well as thicker perigynia 3 mm. or less broad.

Although apparently a recognizable species in Missouri and in most other parts of its range, Gleason (*New Ill. Fl.* 1: 325. 1952) indicated that it may represent only a hybrid with *C. normalis*. However, as shown by Mr. Richard J. Eaton (Rh. 59: 33-36. 1957), it appears to be a recognizable species exhibiting occasional intermediate transitions to *C. brevior* at the northeast margin of its range, as indicated by Dr. Hermann, who considers it quite distinct from *C. brevior* in the midwestern states and east to Pennsylvania and western New York.

36. ***Carex Bicknellii* Britt.** Map 478
Flowers April-July.

Most frequently found in both dry upland prairie and wet river bottom prairie, also in openings on dry wooded chert or limestone slopes. Throughout Missouri, except apparently absent from the extreme southeastern lowland section.

Ranges from Maine to Saskatchewan, south to Delaware, Pennsylvania, Ohio, Indiana, Illinois, Arkansas, Oklahoma, and New Mexico.

This is a fairly tall-growing *Carex*, attaining a height of 1 meter with the flowering culms, which greatly exceed the narrow leaves. The thin, transparent, large

perigynia, mostly 5.5-7.5 mm. long by 2.7-4.8 mm. wide, many-nerved on each face, and the silvery brown or straw-buff light-colored scales and perigynia are marks of recognition. The spikes vary from elongate and tapering at the base to ovoid or subglobose with rounded bases. Specimens with the latter type of rounded bases are sometimes confused with *C. molesta*, from which they may be distinguished by the thinner, flatter, and more translucent perigynia over 3 mm. wide.

37. ***Carex alata* T. & G.** Map 479
Flowers late April-June.

In sink-hole ponds of the southeastern Ozarks in Reynolds, Ripley, Oregon, and Howell counties, and occasionally in open swamps of ditches in the southeastern lowland section in Scott County.

Ranges from Florida to Texas, north near the coast to Massachusetts, New York, and Pennsylvania, inland from New York to Michigan, Indiana, and Missouri.

This is a characteristic species of sink-hole ponds in the Ozarks, where it forms large tussocks or mounds of culms and leaves, often in the crotches of *Cephalanthus* bushes. In such places it is often associated with *Carex comosa*, *C. decomposita*, *Glyceria acutiflora*, *Rosa palustris*, *Viola lanceolata*, *Galium tinctorium*, and *Bidens discoidea*, some of which are also found growing in the tussocks of the *Carex* or among the crotches of *Cephalanthus* bushes.

38. ***Carex straminea* Willd.** Map 480
Carex straminea var. *straminea* [BB]
Carex Richii Mackenz.

Carex hormathodes var. *Richii* Fern.
Flowers early May-June.

Known only from a sink-hole pond in the southern

PLATE NO. 87

481 *Carex leptalea*482 *Carex Jamesii*483 *Carex artilecta*

Ozarks in Shannon County (T₃₁N, R₆W, sect. 32, 7 mi. south of Cedar Grove, May 3, 1947, *Steyermark* 64267; also same locality, June 26, 1951, *Steyermark* 71854, 71855).

Ranges from Massachusetts to Michigan, south to D. C., Indiana, and Missouri.

In this species the culms attain 1 meter in height,

exceeding the leaves. The pale brown spikes are mostly distant and well-separated from one another in an arched, curving or nodding, flexuous, elongated inflorescence, the perigynia are round-ovate to suborbicular, abruptly narrowed to a pronounced beak, and the spikes are long-tapering at the base.

Subgenus II. *Eucarex*

Section 9. *Polytrichoideae*

39. *Carex leptalea* Wahlenb.

Map 481

Flowers May–July.

Occurs in swampy, calcareous, spring-fed meadows and at the base of moist shaded limestone ledges of bluffs along streams and spring branches. Mainly concentrated in a section of the southeastern Ozarks and locally west to Laclede County.

Ranges from Labrador to Alaska, south to North Carolina, Tennessee, Missouri, North Dakota, Colo-

rado, and California.

This is another one of the boreal North American species, which apparently migrated or was forced southward into the Ozarks during one of the early advances of the Pleistocene ice, and has since remained in its present sites as a relict survivor of that period. It is an easily recognizable species with its fine thread-like leaves and single terminal spike of few-flowered, erect-appressed, beakless perigynia.

Section 10. *Phyllostachyae*

40. *Carex Jamesii* Schwein.

Map 482

Flowers late April–July.

Frequents rich woods, occurring in wet and dry situations, on rocky (mostly calcareous) or nonrocky slopes, at the base of bluffs, in flat lowland, and wet swampy forest; usually in neutral to alkaline soils. Common throughout the state, except absent in the southeastern lowland section.

Ranges from New York and Ontario to Michigan and Iowa, south to Virginia, Tennessee, Missouri, and Kansas.

This species is easily recognized in the field by the low dark green clumps of short, soft leaves which mostly exceed the inconspicuous, few-flowered spikes with subglobose, slender-beaked perigynia.

With its clusters of dark green, grasslike leaves, *C. Jamesii* superficially resembles the familiar lily turf (*Ophiopogon japonicus* and *Liriope spicata*), often used for borders or ground plants in conservatories of the northern states or as outdoor turf and pot plants in the southern states.

484 *Carex nigromarginata* var. *nigromarginata*

485 *Carex physorhyncha*

486 • *Carex pensylvanica* var. *pensylvanica*
486 □ *Carex pensylvanica* var. *digyna*

Section 11. **Montanae**

41. ***Carex artitecta*** Mackenz. Map 483
Carex nigromarginata Schw. var. *Muhlenbergii* (Gray)
Gl. in part [BB]
Flowers March–May.

Frequents mostly acid, dry soils of chert, sandstone, and granite, but also on limestone, and on wooded slopes, ridges, uplands, sandstone ledges, openings in woodland, and occasionally on sandy alluvium of low flat woodlands. Throughout Missouri.

Ranges from Maine and Quebec to Ontario, Michigan, Illinois, and Iowa, south to South Carolina, Tennessee, Kansas, and Texas.

This is one of the earliest-flowering species of *Carex*, along with *C. umbellata* and *C. pensylvanica*, to appear in the spring. *Carex artitecta* may be recognized in the field by its nonstoloniferous dense tufts of long slender leaves, which are purplish-red at the base and mostly shorter than the elongated slender culms. The fact that it is one of the first of the *Carex* species to flower, its relative abundance, and its usual affiliation for dry acid wooded soils are additional aids in its field identification.

42. ***Carex nigromarginata*** Schw. var. ***nigromarginata*** Map 484
Carex nigromarginata var. *nigromarginata* [BB]
Missouri material is referred to typical var. *nigromarginata*, the var. *floridana* (Schwein.) Kükenth. being a local Atlantic Coastal Plain variety.
Flowers April–May.

Occurs on acid soils of wooded sandstone slopes, crevices of sandstone or chert outcrops, and on gravelly wooded soils of Crowley Ridge. Rare and known from a few counties of the southern Ozark section (Ste. Genevieve, Bollinger, Wayne, and Douglas counties) and on Crowley Ridge in Dunklin County (Campbell, *Bush* 6397; *Bush* and *Palmer* 3580).

Ranges from Florida to Louisiana, north to Connecticut, New York, Pennsylvania, Indiana, and Missouri.

43. ***Carex physorhyncha*** Liebm. Map 485
Carex nigromarginata var. *Muhlenbergii* (Gray) Gl. in part [BB]
Flowers late April–June.

Known only from two collections in the lowlands of southeastern Missouri, from Mississippi (sandy open ground in Charleston Cemetery, 2 mi. west of Charleston, May 2, 1936, *Steyermark* 10268) and Dunklin (May 17, 1892, *Bush*) counties.

Ranges from Florida to Texas and Mexico, north to Virginia, Missouri, and Oklahoma.

The Dunklin County specimen in the herbarium of the University of Missouri was originally labeled *C. novae-angliae* by Bush, and later identified by Mackenzie as *C. Emmonsii* Dew. The latter species was later treated by Mackenzie under *C. albicans* Willd. (*N. Am. Fl.* 18: 190. 1935), but *C. albicans* is now considered synonymous with *C. Emmonsii*.

44. ***Carex pensylvanica*** Lam. Map 486
This species, including its varieties, sheds considerable pollen, which is occasionally suspected of causing some hay fever.

Missouri material may be divided into two varieties:

Mature perigynia 1.3–1.8 mm. wide, the body obtusely 3-angled in cross-section; beak of perigynium 1/6–2/5 (averaging 1/4) as long as the body . . . 44a. *C. PENSYLVANICA* var. *PENSYLVANICA*
Mature perigynia 1.5–2.2 mm. wide, the body scarcely angled and round or more or less circular in cross-section; beak of perigynium 1/3–1/2 as long as the body . . . 44b. *C. PENSYLVANICA* var. *DIGYNA*

487 *Carex communis*

488 • *Carex umbellata* f. *umbellata*
489 □ *Carex umbellata* f. *vicina*

489 *Carex abdita*

44a. ***Carex pensylvanica* var. *pensylvanica***

Map 486

Carex pensylvanica Lam. [G]

Flowers early April–June.

Occurs in dry acid soils of upland wooded slopes and ridges. Known in northern Missouri from Shelby and Worth counties. This is the less common of the two varieties in the state.

Ranges from Quebec to Ontario and North Dakota, south to South Carolina, Tennessee, and Missouri.

44b. ***Carex pensylvanica* var. *digyna*** Boeckl.

Map 486

Carex heliophila Mackenz. [BB]

Flowers early April–June.

Occurs in dry acid soils of upland wooded slopes and ridges. Common in northern Missouri south to Pike, Montgomery, Randolph, and Jackson counties.

Ranges from Ontario to Alberta, south to New York, Indiana, Illinois, Missouri, Kansas, and New Mexico.

Sometimes treated as a distinct species by some authors, but it seems preferable to consider var. *digyna* as a well-marked western variety of *C. pensylvanica* with which it intergrades in the width of the perigynia and length of the beak.

Closely resembling *C. artitecta* in the field with similar leaves and purplish-red color at the base of the plants, but with leafless horizontal stolons from the base, and perigynia with a more or less globose or subglobose body. The achenes in *C. pensylvanica* also more often have a more whitish or paler gray-white color than those of *C. artitecta*.

45. ***Carex communis*** Bailey

Map 487

Flowers late April–June.

Known from rich woods and wooded limestone slopes from Livingston County in northern Missouri and two counties in southwestern Missouri (Taney Co.: wooded limestone slopes below Table Rock along White River, April 25, 1936, *Steyermark 10116*; Barry Co.: half-way up wooded limestone slopes along White River, east of Smith Ford, south of Shell Knob, April 26, 1936, *Steyermark 10229*).

Ranges from Quebec to Ontario and Minnesota, south to Georgia, Kentucky, and Arkansas.

The stations noted above along White River have now been destroyed by the impoundment of the Table Rock Dam. Other stations from wooded limestone slopes along streams in southwestern Missouri should be carefully searched for new localities where it is expected the species may exist.

46. ***Carex umbellata*** Schkuhr

Map 488

Represented in Missouri by two variations:

Culms all crowded among the bases of the leaves

46a. *C. UMBELLATA* f. *UMBELLATA*

At least some of the culms elongated, 3–20 cm.

tall 46b. *C. UMBELLATA* f. *VICINA*

46a. ***Carex umbellata* f. *umbellata***

Map 488

Carex umbellata Schkuhr [G, BB, P & S]

Flowers late March–May.

Occurs in acid soils of dry upland woods, often on cherty, sandstone, or granitic soils, on slopes, crests of hills, ridges, and upland areas, also on sandstone outcrops and in dry prairie, prairie openings, open grassy slopes, and upland pastures. The commoner variation in Missouri, where it occurs throughout the Ozark region, and north locally in northern Missouri to Shelby, Linn, Grundy, and Daviess counties; absent

PLATE NO. 88

490 *Carex tonsa*491 *Carex eburnea*492 *Carex hirtifolia*

from the lowland section of southeastern Missouri.

Ranges from Newfoundland to Ontario and Minnesota, south to Virginia, Indiana, Illinois, and Missouri.

Like *C. artitecta* and *C. pennsylvanica*, this species is one of the earliest of *Carex* species to flower in the spring. It is often overlooked, because of its resemblance to a bunch of grass and because the flowering culms are usually hidden among the leaves. In this respect it is like the closely related *C. abdita* and *C. tonsa*.

46b. *Carex umbellata* f. *vicina* (Dew.) Wieg.

Map 488

Scattered throughout the range of the typical form and often occurring with it.

47. *Carex abdita* Bickn.

Map 489

Carex umbellata var. *brevirostris* Boott

Carex microrhyncha Mackenz.

Carex umbellata in part [of P & S], not Schkuhr

Flowers late March–May.

Occurs in rocky open ground, prairies, prairie openings, and dry open woods. Found in western Missouri east to Gentry, Polk, and Douglas counties. Future collecting should reveal a greater frequency of occurrence of this species.

Ranges from Newfoundland and Saskatchewan, south to Virginia, Tennessee, Illinois, and Missouri.

This differs from *C. umbellata* mainly in the smaller perigynia with shorter beaks, and in the shorter, less pointed tips of the pistillate scales.

48. *Carex tonsa* (Fern.) Bickn.

Map 490

Carex umbellata var. *tonsa* Fern.

Flowers April–June.

Known only from the southeastern Ozarks in Ste. Genevieve County (sandstone wooded slopes of La Motte sandstone outcrops and bluffs along River aux Vases, T36N, R7E, sect. 26 and 27, 3½–4 mi. north-west of Coffman, May 11, 1957, *Steyermark 84407*).

Ranges from Quebec and Alberta, south to Virginia, Indiana, Wisconsin, Missouri, and Minnesota.

Differing from *C. umbellata* and *C. abdita* in the glabrous instead of pubescent perigynia with longer beaks, and in the firmer, more scabrous and broader leaves.

By some authors the last three species are united under *C. umbellata*. However, the various characters by which *C. abdita*, *C. tonsa*, and *C. umbellata* are distinguished appear to be fairly constant in the main, and, pending additional experimentation, it would seem preferable to retain them in separate specific rank.

Section 12. *Albae*

49. *Carex eburnea* Boott

Map 491

Flowers April–August.

Frequents the crevices of limestone bluffs, rarely found otherwise on bluffs of St. Peter sandstone or on the ground at the base of limestone talus. Common throughout the entire Ozark section, north to Pike, Monroe, and Boone counties, west to Cooper, Henry, St. Clair, and McDonald counties.

Ranges from Newfoundland to Alaska, south to Virginia, Alabama, Arkansas, and Texas.

By its distinctive habitat alone, this species can be easily identified. This, together with its tufts of numerous, fine, threadlike leaves, few-flowered spikes with pale pistillate scales, and small olive-green to black perigynia, make it further readily recognized in the field.

493 *Carex Meadii*494 *Carex tetanica*495 *Carex Woodii*Section 13. **Triquetrae**50. ***Carex hirtifolia*** Mackenz.

Map 492

Flowers late April–late June.

Frequents rich wooded areas with or without rock outcrops, on slopes, in ravine bottoms, and flat level wooded valleys. Known only from northern, central, and eastern Missouri; absent from the greater part of the Ozarks, southeastern lowland, and unglaciated

prairie sections.

Ranges from New Brunswick and Quebec to Ontario and Minnesota, south to Maryland, Kentucky, Missouri, and Kansas.

The soft hairy leaves and culms, together with the habitat in rich woodland, easily identify this *Carex* in the field.

Section 14. **Paniceae**51. ***Carex Meadii*** Dew.

Map 493

Flowers late March–June.

Occurs principally on limestone glades and dry upland prairies or prairie openings, also in wet meadows in valleys, and along railroads. Throughout Missouri, except absent in the southeastern lowland section; commonly found throughout the Ozark section on limestone or cherty limestone glades and on top of limestone bluffs.

Ranges from New Jersey, Pennsylvania, Ontario, Michigan, Wisconsin, Minnesota, Manitoba, and Saskatchewan, south to Georgia and Texas.

This is usually easily recognized in the field by the combination of limestone glade or prairie habitat, elongated underground rootstocks, usually glaucous or gray-green stiffish leaves, purplish-brown pistillate scales, glaucous or gray-green perigynia, and usually slender club-shaped staminate spike conspicuously raised on a long stalk. The only other species for which it can be mistaken are *C. Crawei*, which also occurs on limestone glades, and *C. tetanica*, known only from the loess hills of Atchison County. The main differences lie in the pistillate spikes and perigynia: in *C. Crawei* there are usually 3 or 4 pistillate spikes scattered along the length of the culm, some of the lower spikes being on distinct stalks, the dull green to brown perigynia, which taper to a short straight beak,

are few-nerved, broadest at or below the middle and often resinous-dotted; in *C. Meadii* there are frequently only 1 or 2 sometimes sessile or stalkless pistillate spikes, the glaucous to pale green or greenish-white perigynia, which taper to the base and have a bent or curved beak, are strongly several-ribbed, broadest in the upper half, and not resinous-dotted.

As compared with *C. Meadii*, *C. tetanica* has the leaves thinner and green without being glaucous, the pistillate spikes are more slender with fewer rows of perigynia, which are closer together, straight, not as wide, less inflated, and more gradually tapering to the tip. However, plants which are intermediate and have overlapping combinations of characters occur and are difficult to place, as likewise noted for Indiana material by Hermann (Deam, *Flora of Indiana*, p. 245. 1940).

52. ***Carex tetanica*** Schkuhr

Map 494

Carex tetanica var. *tetanica* [BB]

Flowers May–late June.

Known only from the loess hills of northwestern Missouri in Atchison County (Watson, June 1, 1894, *Bush* 696).

Ranges from Massachusetts to Alberta, south to Virginia, Pennsylvania, Ohio, Indiana, Illinois, northwestern Missouri, and South Dakota.

496 *Carex Careyana*

497 • *Carex digitalis* var. *digitalis*
497 □ *Carex digitalis* var. *macropoda*

498 *Carex laxiculmis*

Specimens from limestone glades in the White River section of southwestern Missouri, identified by their collectors as *C. tetanica*, have been referred by the present author to *C. Crawei*. *Carex tetanica* differs from *C. Crawei* mainly in having the perigynia glaucous, greenish-white, or gray-green, broadest in the upper half, tapering at the base, and strongly several-ribbed, and in the thinner, greener, not glaucous leaves.

53. ***Carex Woodii* Dew.**

Map 495

Carex tetanica var. *Woodii* (Dew.) Bailey [BB, P & S in part]

Flowers late April-June.

Known only from the southern Ozarks in Howell County (swampy meadow along spring branch along Bennett Bayou, sect. 30, 5 mi. south of Caulfield, April 29, 1938, *Steyermark 5237*).

Ranges from Connecticut and New York to Manitoba, south to D. C., Ohio, Indiana, Illinois, and Missouri.

The only known station thus far encountered in the state is from a moist, calcareous, spring-fed meadow, quite unlike the woodland, although calcareous, habitats ascribed for the species in other parts of its range.

Section 15, **Laxiflorae**

54. ***Carex Careyana* Torr.**

Map 496

Flowers May-June.

Frequents rich woods, especially north-facing wooded limestone slopes, also in ravines, wooded valleys, and at the base of slopes. Restricted to the Ozark section in unglaciated terrain north to Lincoln, Callaway, and Boone counties, and west to Dallas, Christian, and Stone counties.

Ranges from New York to Ontario and Michigan, south to Virginia, Ohio, Indiana, Illinois, and Missouri.

This species develops rosettes of basal evergreen leaves which are prominently many-nerved and dark reddish-purple at the very base. The leaves, which are 8-17 mm. wide, may be distinguished from *C. albursina*, which also has persistent evergreen leaves, by the reddish-purple color at the base, by the darker green, not glaucous upper leaf surface, and by the relatively narrower (8-17 mm. wide as contrasted with usually 15-40 mm.) leaf-blades.

55. ***Carex digitalis* Willd.**

Map 497

Flowers May-July.

Missouri material is represented by 2 variations within the species:

Upper pistillate spikes short-stalked or nearly stalkless; staminate spike on stalks 0.2-3 cm. (rarely 4.5) long; staminate spike of the inflorescence usually rising above the middle bract of the inflorescence; culms 0.5-5 dm. tall . . .

55a. *C. DIGITALIS* var. *DIGITALIS*

All the pistillate spikes on long stalks; staminate spike on stalks 5-20 cm. long; inflorescence more frequently shorter than the leaf-like middle bract; culms 3-6 dm. tall . 55b. *C. DIGITALIS* var. *MACROPODA*

55a. ***Carex digitalis* var. *digitalis***

Map 497

Carex digitalis Willd. [G, BB, P & S]

Occurs usually on north- or northwest-facing dry wooded slopes in acid soils, often of chert, sand, or sandstone, sometimes in crevices of shaded sandstone ledges or bluffs, also in ravines or at the base of

PLATE NO. 89

499 *Carex albursina*500 *Carex blanda*501 *Carex gracilescens*

slopes in limestone areas, and also along wooded moist margins of upland sink-hole ponds.

This, the commoner variety in the state, is found in the Ozark section, occurring north to St. Charles, Franklin, and Maries counties, and west to Wright and Taney counties, and in the southeastern lowland section on Crowley Ridge in Dunklin County.

Ranges from Maine to Ontario and Wisconsin, south to Florida, Mississippi, and Missouri.

55b. ***Carex digitalis* var. *macropoda*** Fern.

Map 497

In similar habitats to var. *digitalis*.

Scattered within the range of var. *digitalis* in Warren (*Steyermark* 73327), Bollinger (*Steyermark* 69613 a), and Crawford counties.

Ranges from Virginia to Missouri, south to Alabama and Louisiana.

Some authors are inclined not to recognize the above variety *macropoda* because of intergrading and noncorrelating characters. Until more studies have been conducted throughout the range of the plants, they are, for the present, being retained as recognizable, intergrading varieties.

56. ***Carex laxiculmis*** Schwein.

Map 498

Flowers May-June.

Frequents rich wooded areas, especially north-facing limestone slopes, ravines, and wooded valleys. Rare, known only from Bollinger, Madison, Ripley, Oregon, and Shannon counties in the southeastern Ozark section.

Ranges from Maine to Ontario and Wisconsin, south to North Carolina, Tennessee, and Missouri.

The specimen from Shannon County, previously included by Palmer & Steyermark in their *Annotated Catalogue* as *C. laxiculmis* var. *copulata* (Bailey) Fern. is now referred to *C. laxiculmis*. *Carex laxiculmis* var. *copulata* is treated by Fernald in the eighth edition of *Gray's Manual* as *C. × copulata* (Bailey) Mack., con-

sidered to be a hybrid between *C. digitalis* var. *digitalis* and *C. laxiculmis*. It differs from *C. laxiculmis* in having culms with sharp instead of blunt angles, sheaths of the bracts of the inflorescence minutely serrulate-toothed, instead of entire, and perigynia rounded, blunt, or round-tapering at the tip and abruptly short-beaked.

57. ***Carex albursina*** Sheldon

Map 499

Carex laxiflora Lam. var. *latifolia* Boott [BB]

Flowers late April-late June.

Usually found on north-facing wooded, rich or limestone slopes, throughout the Ozarks, and locally north to Clark, Schuyler, Boone, Saline, Caldwell, and Jackson counties; absent from the southeastern lowland section and from parts of western Missouri.

Ranges from Quebec and Vermont to Minnesota, south to Virginia, Tennessee, and Arkansas.

The habitat and broad, gray-green, lilylike leaves, which are the largest of any of the species in Missouri, serve to identify this sedge easily in the field.

58. ***Carex blanda*** Dew.

Map 500

Carex laxiflora var. *blanda* (Dewey) Boott [BB]

Carex anceps of P & S, not Muhl.

Flowers April-July.

Found in dry or wet woodland of all types, low wet woods, ravines, rich wooded slopes with or without rocks, alluvial thickets, and along rivers. Found throughout the state, and of expected occurrence in every county.

Ranges from Quebec to Ontario and North Dakota, south to Alabama and Texas.

This species varies in its foliage from dull green to glaucous, with leaf-blades 4-12 mm. wide. It is the most abundant and commonest species of *Carex* in Missouri, as it is also in Indiana and some other states. After eventually becoming acquainted with it, it becomes an easily recognized, if somewhat variable, species.

502 • *Carex granularis* var. *granularis*
502 □ *Carex granularis* var. *haleana*

503 *Carex Crawei*

504 *Carex microdonta*

By Gleason (*New Ill. Fl.* 1: 336. 1952) this species is considered, along with *C. albursina*, *C. gracilescens*, and other species, as varieties of *C. laxiflora*. The group has long been subjected to various interpretations. In the present treatment the works of Fernald and Hermann, which maintain these as separate species, are being followed.

59. ***Carex gracilescens* Steud.** Map 501
Carex laxiflora var. *gracillima* (Boott) Robins. & Fern. [BB]
Carex laxiflora in part [P & S], not Lam.
Flowers late April–June.

Most frequently occurring in rich usually dry woods, with or without rocks, on or at the base of slopes, ravines, and valleys. Scattered over the state, and much less common than *C. blanda*; rare in the northern half of the state.

Ranges from Vermont and Quebec to Ontario and Wisconsin, south to Alabama and Texas.

With repeated experience this species can be readily distinguished from *C. blanda* by the usually long-stalked, brown to purplish staminate spike, the more strongly curved and slender snoutlike beak of the perigynia, and the dark purplish- or mahogany-red or purplish-brown color at the base of the culms.

Section 16. **Granulares**

60. ***Carex granularis* Muhl.** Map 502
Flowers late April–late July.
Two varieties are represented in Missouri:

Perigynia 2.5–4 mm. long, 1.5–2.5 mm. wide, broadly ovoid to subglobose, becoming squarrose at maturity with spreading or outward-turning tapering tips . 60a. *C. GRANULARIS* var. *GRANULARIS*

Perigynia mainly 2–2.8 (–3) mm. long, 1–1.5 mm. wide, narrowly ovoid or oblong-ellipsoid, more or less erect-ascending and appressed at maturity, with rounded and abruptly minutely beaked tips not outwardly spreading or turning

60b. *C. GRANULARIS* var. *HALEANA*

Ranges from Vermont to Ontario and Minnesota, south to Florida, Arkansas, and Kansas.

- 60b. ***Carex granularis* var. *Haleana* (Olney)** Porter Map 502

Most often occurring in moist crevices of limestone bluffs, on rocky limestone glades, along spring branches, in swampy woods or wooded flood plain, and less commonly in wet open prairies. Less common than var. *granularis* in Missouri, where it is restricted to the Ozark section north to St. Louis, Osage, and Cooper counties, west to Hickory and Jasper counties.

This is sometimes treated as a distinct species by some authors. Both varieties often have glaucous or nearly glaucous leaves.

- 60a. ***Carex granularis* var. *granularis*** Map 502
Frequent in wet woods and wooded swamps or alluvial flood plain, along streams, spring branches, spring-fed calcareous swampy meadows, moist limestone ledges of bluffs, river bottom prairies, and prairie swales. Common throughout the Ozark and unglaciated prairie sections and scattered in northern Missouri; apparently absent from the northwestern portion of the state.

61. ***Carex Crawei* Dewey** Map 503
Flowers April–June.

Found on limestone glades, but rather rare, with two concentrations of occurrence, one in the north-eastern sector of the Ozarks, the other in the south-western sector, with an isolated station along the northern Ozark border in Morgan County.

505 *Carex oligocarpa*506 *Carex Hitchcockiana*507 *Carex conoidea*

Ranges from Quebec to Alberta, south to New Jersey, Alabama, Tennessee, Missouri, Kansas, Wyoming, and Washington.

This species is frequently confused with *C. Meadii* and *C. tetanica* (see under *C. Meadii* and *C. tetanica* for their separation).

62. ***Carex microdonta*** Torr. & Hook. Map 504

Flowers April–July.

Occurs on limestone glades, dry prairies, and wet calcareous open soils. Rare, and known only from Osage (*Steyermark 27682*), Clay, Vernon, and Bates (*Palmer 53869*) counties in western and central Missouri.

Ranges from Missouri and Oklahoma, south to Mississippi and Texas.

Section 17. **Oligocarpae** (including section *Griseae*)

63. ***Carex oligocarpa*** Schkuhr Map 505
Flowers late April–July.

Commonly found on north-facing, well-drained, wooded limestone slopes and on rich wooded slopes and ravines, also in alluvial flood plain forest, ledges along limestone bluffs, and rarely on open grassy slopes. Absent from the southeastern lowland section, elsewhere widespread in Missouri, especially in limestone wooded sections of the Ozarks.

Ranges from Vermont, Quebec, Ontario, and Michigan to Iowa, south to Florida and Texas.

Frequently confused with the varieties of *C. amphibola* having narrow leaves and slender pistillate spikes (for discussion of which see under that species). The base of the culms in *C. oligocarpa* has a dark purplish-red color.

64. ***Carex Hitchcockiana*** Dew. Map 506
Flowers May–June.

Occurs in rich woods, with or without rock, often on north-facing wooded limestone slopes, and in rich ravines or forested valleys. Rather rare and scattered in parts of northern Missouri and the Ozark region; apparently absent from the southeastern lowland and unglaciated prairie sections.

Ranges from Quebec and Vermont to Ontario and Wisconsin, south to Virginia, Tennessee, and Missouri.

The habitat, purple-red base of the plants, and pubescent leaf-sheaths are field characters which should aid in identifying this distinct species. The pubescence on the sheaths is short but evident. The species is often associated with other rich woods-inhabiting species of *Carex*, such as *C. hirtifolia*, *C. Jamesii*, *C. oligocarpa*, *C. albursina*, *C. sparganioides*, *C. blanda*, and *C. Careyana*.

65. ***Carex conoidea*** Schkuhr Map 507
Flowers May–June.

Known only from upland virgin prairies in Callaway County, central Missouri (virgin prairie [Tucker Prairie], west of Kingdom City, June 7, 1940, *W. B. Drew 104*) and Phelps County, central Ozarks (virgin prairie along creek, T36N, R7W, sect. 17, 2 mi. southwest of Elk Prairie, about 10 mi. southeast of Rolla, May 7, 1951, *Steyermark 71201*).

Ranges from Newfoundland to Ontario and Minnesota, south to Delaware, Ohio, Indiana, Illinois, and Missouri.

This species is distinguished from *C. Crawei* and *C.*

PLATE NO. 90

508 • *Carex amphibola* var. *amphibola*
 508 x *Carex amphibola* var. *rigida*
 508 + *Carex amphibola* var. *turgida*
 508 □ *Carex amphibola* var. *globosa*

509 • *Carex flaccosperma* var. *flaccosperma*
 509 □ *Carex flaccosperma* var. *glaucodes*

510 *Carex gracillima*

Meadii, which it resembles, in the deep green instead of glaucous leaves, the relatively long- and rough-awned pistillate scales which equal or exceed the perigynia, and the bunched culms.

66. ***Carex amphibola* Steud.** Map 508
 Flowers late April–July.

This species is usually either divided into *C. grisea* and *C. amphibola*, or is split up into 4 separate rather poorly marked varieties of *C. amphibola*. Either procedure has its difficulties, but, since it does not seem that two distinct species can be represented in the mass of variation found in Missouri, the course followed in the present work is to maintain the division into the 4 named varieties, the main distinctions of which are outlined in the following key:

- a. Base of plant strongly tinged purplish- or wine-red; leaves 1.5–4 mm. wide; mature perigynia rather tightly surrounding the achene, scarcely or little inflated; pistillate spikes often widely separated, the lower ones near the base of the plant. 66a. *C. AMPHIBOLA* var. *AMPHIBOLA*
- a. Base of plant usually brown or green; leaves mainly 4–10 mm. (or as little as 2) wide; mature perigynia mostly loose around the achene and more or less definitely inflated; pistillate spikes more approximate, the lowest not near the base of the plant. b
- b. Perigynia somewhat narrowed or tapering at both ends, obtusely angled, somewhat inflated; pistillate spikes 3–6 mm. thick; staminate spike usually elevated conspicuously above the nearest pistillate spike. 66b. *C. AMPHIBOLA* var. *RIGIDA*
- b. Perigynia more rounded at both ends, with rounded angles, definitely more inflated; pistillate spikes 5–8 mm. thick; staminate spike usually partly surpassed or hidden by the upper pistillate spike. c

- c. Main leaf-blades 4–10 mm. wide; larger pistillate spikes 7–20-flowered, 1–3 cm. long; perigynia 4–5.5 mm. long, more or less oblong, definitely longer than thick 66c. *C. AMPHIBOLA* var. *TURGIDA*
- c. Main leaf-blades 2–5 mm. wide; larger pistillate spikes 3–7-flowered, 0.7–2 cm. long; perigynia 4–4.5 mm. long, nearly globose to obovoid-oblong, slightly longer than thick or nearly as thick as long 66d. *C. AMPHIBOLA* var. *GLOBOSA*

66a. ***Carex amphibola* var. *amphibola* Map 508**
Carex amphibola Steud. [BB, P & S, G, Deam]

Found in rich woods, with or without rock, often on north-facing wooded limestone slopes, or in ravines, wooded valleys, low wet or alluvial forested areas, and along streams. Scattered in Missouri, apparently more common in the northern and eastern sectors.

Ranges from Florida to Texas, north to Delaware, Pennsylvania, Tennessee, and Missouri.

The separation of this variety from *C. oligocarpa* often offers great difficulties, as the two overlap in such characters as few-flowered pistillate spikes with cuspidate or awned scales, relatively tight perigynia narrowed or tapering at both ends, narrow leaves, purplish-red base of culms, and elevated staminate spikes. In fact, the only criterion for placing such overlapping types in one or the other species is on the basis of the more definitely angled and beaked perigynium nearly filled by the achene in *C. oligocarpa* contrasted with a more obscurely or obtusely angled, scarcely or not beaked perigynium empty above in *C. amphibola* var. *amphibola*. Since both *C. amphibola* var. *amphibola* and var. *rigida* have the perigynium somewhat tapering to base and summit, the character of the tapering base characteristic of *C. oligocarpa* cannot be used as a mark of separation between these three. Likewise, the few-flowered pistillate spikes and

narrow leaf-blades of *C. amphibola* var. *globosa*, characters also found in *C. oligocarpa*, cannot be used in separating these two.

66b. ***Carex amphibola* var. *rigida*** (Bailey) Fern. Map 508

Carex grisea var. *rigida* Bailey [P & S]

Carex grisea Wahl. in part [BB, Deam]

In similar situations as var. *amphibola*.

Scattered over the state.

Ranges from Florida to Texas, north to Massachusetts, New York, Indiana, Illinois, and Missouri.

The pistillate spikes in this variety are usually 5–20-flowered and 1–2.5 cm. long, and the leaf-blades mainly 3–7.5 mm. wide. As this variety has the perigynia somewhat tapering at the base and summit, similar to the condition in *C. oligocarpa*, the main points for separating it from that species are the relatively broader leaves, and more crowded, usually more numerous, slightly more inflated perigynia of the pistillate spikes.

Some of the earlier students (Bailey, Mackenzie) have been puzzled by this variety, and Fernald (Rh. 44: 314. 1942) considers it intermediate between the var. *amphibola* and var. *turgida*.

66c. ***Carex amphibola* var. *turgida*** Fern.

Map 508

Carex grisea Wahlenb. in part [BB, P & S, Deam]

Usually found in wet, low or alluvial woodland, along streams, and in rich woods, ravines, and valleys. Throughout Missouri, where it appears to be the commonest variation of the species.

Ranges from New Brunswick to Ontario and Minnesota, south to Georgia, Alabama, Louisiana, and Texas.

In this variety the plants are much more robust, from 2–8 dm. tall, the leaf-blades are broader (4–10 mm. wide) than in the other varieties, and the pistillate spikes are thicker and longer with more perigynia. In fact, var. *turgida* stands at the opposite extreme of variation from that shown by *C. amphibola* var. *amphibola*, and in their extremes these two varieties can be readily distinguished. It is the intergradation between them and the other varieties which makes it difficult to recognize sharp distinctions in the group of *C. amphibola*.

66d. ***Carex amphibola* var. *globosa*** Bailey

Map 508

Carex grisea var. *globosa* Bailey [P & S]

Carex grisea Wahlenb. in part [BB, Deam]

In similar habitats to var. *amphibola* and var. *turgida*.

Scattered throughout Missouri.

Ranges from Louisiana and Texas, north to Missouri.

Fernald has discussed at some length the perplexities encountered in the variation and nomenclature of *C. amphibola* and *C. grisea* (Rh. 44: 311–15. 1942). In view of the statement made by him that there is considerable doubt as to the true identity of what is being called *C. amphibola* on account of the mixed material contained in the original specimen, together with the doubtful application of the name *C. grisea*, it can be seen that there would be little justification in assigning two doubtful specific names to the mass of Missouri material. So far as attempting to divide this material into the two species, *C. grisea* and *C. amphibola*, such a course of procedure inevitably leads to the hopeless attempt to place plants having purple-based culms of *C. amphibola* with leaf-blades of 4–10 mm. wide, supposedly characteristic of *C. grisea*. The more conservative treatment as here presented reflects the uncertainties of the present status of an admittedly confused group, which needs considerably more study.

The very fact that there is difficulty in distinguishing some of the variations of *C. amphibola* (such as *C. amphibola* var. *amphibola*) from *C. oligocarpa* would seem to justify the placing of these two species into the same section, as was done by Fernald and likewise followed in the present work, rather than placing *C. oligocarpa* and *C. amphibola* in separate sections *Oligocarpeae* and *Griseae* respectively, as was done in the works of Gleason and Deam.

67. ***Carex flaccosperma*** Dew.

Map 509

Missouri material is represented by two varieties:

Foliage green to somewhat glaucous (gray- or silvery green); perigynia 4–6 mm. long; swampy ground in extreme southeastern Missouri . . .

67a. *C. FLACCOSPERMA* var. *FLACCOSPERMA*

Foliage definitely glaucous; perigynia 3–5 mm. long; throughout the Ozark section in dry, open or rocky woodland, often on ridges and upland slopes, or in valley woods along streams. . .

67b. *C. FLACCOSPERMA* var. *GLAUCODEA*

67a. ***Carex flaccosperma* var. *flaccosperma***

Map 509

Carex flaccosperma Dew. [G, BB, P & S]

Flowers May–early June.

In low wet woodland or swampy ground, in the lowland section of southeastern Missouri, where known only from Dunklin (moist ground, May 17 and May 20, 1892, *Bush*) and Ripley (depression in wooded swamp surrounded by sandy wooded knolls,

511 *Carex oxylepis*512 • *Carex Davisii* f. *Davisii*
513 □ *Carex Davisii* f. *glabrescens*513 *Carex debilis* var. *debilis*

T22N, R4E, southeast sect. 35, 4 $\frac{3}{4}$ mi. south of Naylor, May 28, 1951, *Steyermark* 71239) counties.

Ranges from Florida to Texas, north to Virginia, Tennessee, and southeastern Missouri.

At the station in Ripley County, this sedge was associated with the rare and local shrub, *Lindera melissaefolium*, and with *Carex debilis* var. *debilis*, *C. gigantea*, *C. typhina*, *C. crus-corvi*, *C. caroliniana*, and other species of the genus, as well as with other plants characteristic of the flora of the Atlantic coastal plain and Mississippi River Embayment of the gulf coastal plain.

67b. ***Carex flaccosperma* var. *glaucodea***

(Tuckerm.) Kükenth.

Map 509

Carex glaucodea Tuckerm. [BB, P & S]

Flowers late April–early July.

Frequents usually acid soils of sandstone, chert, or granite wooded slopes, upland ridges, ravines, in usually dry situations, sometimes in wooded valleys along streams. Throughout the Ozark section west to Boone, Moniteau, Morgan, Dallas, Webster, and Douglas counties, north to Pike County, and locally in northeast Missouri in Lewis County.

Ranges from Alabama to Louisiana, north to Massachusetts, New York, Ontario, Ohio, Indiana, Illinois, and Missouri.

An easily recognized *Carex*, because of the thick glaucous leaves, which last throughout the winter months. This sedge is accepted by some authors as a distinct species. The overlapping range of the length of perigynia and the sometimes glaucous foliage of var. *flaccosperma* appear justifiable grounds for including the two under one species.

Section 18. **Gracillimae**

68. ***Carex gracillima* Schwein.**

Map 510

Flowers late May–late June.

Occurs in low woods along streams. Very rare, and known only from St. Louis (Fox Creek bottoms, Allenton, June 10, 1887, *Eggert*) and Greene (Springfield, June 16, 1889, *S. Weller* in Drury College Herbarium) counties.

Ranges from Newfoundland to Manitoba, south to Virginia, Tennessee, and Missouri.

69. ***Carex oxylepis* Torr. & Hook.**

Map 511

Flowers late April–July.

Occurs in low rich damp woodland or in acid soils of dry sandy wooded knolls, and wet sandy ground. Known only from the southeastern lowland section in either low ground or on knolls of Crowley Ridge, in

New Madrid (*Steyermark* 69659), Pemiscot (*Steyermark* 82256), Dunklin (May 24, 1893, *Eggert*; May 17, 1892, *Bush*; *Steyermark* 26580A), and Butler counties.

Ranges from Florida to Texas, north to Virginia, Tennessee, and southeastern Missouri.

This species grows in either rich lowland wooded areas or on dry sandy wooded slopes and knolls. At the Pemiscot County station, where it occurred in a virgin wooded section 3 mi. southwest of Portageville, it was associated with the rare and local *Polymnia laevigata*, and with such species of *Carex* as *C. Grayii*, *C. Frankii*, *C. tribuloides*, and *C. louisianica*. At the New Madrid County locality it occurred on dry sandy acid soils with *Quercus stellata*, *Q. falcata*, *Ulmus alata*, *Panicum Boscii* var. *molle*, *Carex artitecta*, *Galium pilosum*, and *Aster patens*.

PLATE NO. 91

514 *Carex cherokeensis*515 *Carex virescens*516 *Carex Swani***70. *Carex Davisii* Schw. & Torr.**

Map 512

Flowers May–July.

Occurs in low or wet woods, wooded alluvial soils of river flood plain, along streams, open fields and valleys, and on wooded rich slopes in ravines or valleys. Throughout northern, western, and central Missouri, less common in the Ozark section and absent in many parts of that section; apparently absent from the lowlands of southeastern Missouri.

Ranges from Vermont to Michigan and Minnesota, south to Maryland, Tennessee, Missouri, Oklahoma, and Texas.

Two variations are encountered in Missouri:

Leaf-sheaths and usually the lower surface of the leaf-blades more or less hairy. . . 70a. *C. DAVISII* f. *DAVISII*

No hairs present on leaf-sheaths or leaf-blades, the plant completely glabrous. . . 70b. *C. DAVISII* f. *GLABRESCENS*

70a. *Carex Davisii* f. *Davisii*

Map 512

Carex Davisii Schw. & Torr. [G, BB, P & S]

This is the commoner variation found throughout the state.

70b. *Carex Davisii* f. *glabrescens* Kükenth.

Map 512

Known only from Newton (thickets along brook, George Washington Carver National Monument, May 2, 1959, *Palmer 68561*; moist ground, thickets along brook, George Washington Carver National Monument, June 29, 1959, *Palmer 68562*) and St. Louis (*Eggert*) counties.

This species is common throughout the northern half of the state. During the growth of the plant, various modifications in the development of the pistillate spikes and perigynia produce corresponding changes of gross appearance. At first the pistillate spikes are erect, later they may become spreading or nodding. Likewise, the perigynia at first are pale green, but later turn to brown or yellow-brown. The pubescent leaf-sheaths and usually the pubescent lower surface of the leaf-blades are distinctive marks of this species.

Section 19. *Sylvaticae***71. *Carex debilis* Michx.**

Map 513

Flowers late May–August.

Two varieties are represented in Missouri:

Perigynia 6–10 mm. long, narrowly lanceolate, broadest below the middle, gradually tapering to the tip; scales of pistillate flowers usually pale, whitish, or greenish-white. . . 71a. *C. DEBILIS* var. *DEBILIS*

Perigynia 4.5–7 mm. long, broadly or ovate-lanceolate, broadest at or near the middle, more abruptly tapering to the tip; scales of pistillate flowers usually tinged with brown. . . 71b. *C. DEBILIS* var. *RUDGEI*

71a. *Carex debilis* var. *debilis*

Map 513

Known from low swampy woods in the south-

eastern Missouri lowlands in Stoddard (T25N, R11E, sect. 6, 3½ mi. southeast of Bloomfield, August 20, 1954, *Steyermark 76827*) and Ripley (T22N, R4E, southeast sect. 35, 4¼ mi. south of Naylor, May 28, 1951, *Steyermark 71228*) counties.

Ranges from Florida to Texas, north along the coast to Massachusetts and inland north to Indiana and southeastern Missouri.

At the Ripley County station this sedge was growing with the rare and local *Lindera melissaefolium* in swampy depressions surrounded by sandy wooded knolls. At the Stoddard County station it was associated with *Commelina virginica*, *Osmunda cinnamomea*, and *Ilex opaca*.

71b. ***Carex debilis* var. *Rudgei*** Bailey Map 513
Recorded from Missouri.
Ranges from Newfoundland to Ontario, Wisconsin,

and Minnesota, south to Virginia, Tennessee, and Missouri.

Section 20. **Longirostres**

72. ***Carex cherokeensis*** Schw. Map 514
Flowers April–May.
Known only from low wet woods in the lowlands of southeastern Missouri in Butler County (May 1,

1905, *Bush 2658*).
Ranges from Florida to Texas, north to Georgia, Tennessee, southeastern Missouri, and Oklahoma.

Section 21. **Virescentes**

73. ***Carex virescens*** Muhl. Map 515
Flowers mid-May–July.
Occurs usually in acid soils of wooded sandstone ledges, north- or northwest-facing wooded slopes of chert or sandstone, more rarely at the base of wooded limestone slopes, and also in moist ground either in sandy moist soils along spring branches, or in low wet woods in the valleys of streams. Known only from a few stations in the southeastern Ozark section west locally to Texas County, and on Crowley Ridge in Stoddard County adjacent to the southeastern lowland section.
Ranges from Maine to Quebec, Michigan, and Indiana, south to Georgia, Tennessee, and Missouri.

C. virescens is usually found on drier slopes and ledges in better-drained sites.

74. ***Carex Swanii*** (Fern.) Mackenz. Map 516
Carex virescens [of P & S], not Muhl.
Flowers mid-May–July.
Occurs in wet woods and swampy low ground. Known only from the lowlands of southeastern Missouri in Scott, Dunklin, Butler, and Ripley counties.
Ranges from Nova Scotia to Ontario and Wisconsin, south to North Carolina, Tennessee, and Arkansas.
This species is found in low moist woods, whereas

75. ***Carex complanata*** Torr. & Hook. Map 517
Missouri material is represented by 2 varieties, whose differences are indicated in the key to species.

75a. ***Carex complanata* var. *complanata*** Map 517
Flowers May–early July.
Occurs on dry upland open wooded slopes in western Missouri in Vernon and Worth (*Steyermark 65565*) counties.
Ranges from Florida to Texas, north near the coast to New Jersey, inland north to Tennessee and Missouri.

75b. ***Carex complanata* var. *hirsuta*** (Bailey) Gl. Map 517
Carex hirsutella Mackenz. [G, P & S]
Flowers May–July.
Frequents dry acid soils of open wooded slopes, ridges, and upland, mostly in cherty, sandstone, or granitic soils of the Ozarks or in sterile sandy or clay

520 *Carex lanuginosa*521 *Carex scabrata*522 • *Carex Shortiana*
522 □ *Carex X Deamii*

soils elsewhere. Common in most parts of the state, but absent from the extreme northwestern counties and from a few in the extreme western and southeastern lowland sections.

Ranges from Maine and Quebec to Ontario, Michigan and Iowa, south to Alabama, Arkansas, and Texas.

This is one of the commonest and most frequently encountered species of *Carex* in Missouri on the drier upland and acid soils of open woodland, where it is associated frequently with *Carex artitecta*, *C. umbellata*, and *Danthonia spicata*.

The differences separating this from *C. complanata* var. *complanata* do not seem sufficiently well-marked or sharp enough to maintain the two as separate species, and I agree with Gleason's interpretation of this species in his *New Illustrated Flora* 1: 348. 1952.

76. ***Carex caroliniana*** Schw. Map 518
Flowers May-June.

Frequents low wet woods or wooded swamps and river flood plain forest, also in prairie openings, prairie

swales, open grassy slopes, and upland pastures and prairies. Scattered in southern and central Missouri, north to St. Louis, Cooper, and Jackson counties.

Ranges from Georgia to Texas, north to New Jersey, Pennsylvania, Ohio, Indiana, Missouri, and Oklahoma.

77. ***Carex Bushii*** Mackenz. Map 519
Flowers early May-early July.

Frequently found in dry upland prairies, prairie openings, open grassy slopes, dry fields and pastures, wet river bottom prairie, wet open swales in meadows and valleys, along railroads, borders of ponds, open swamps and ditches, openings in dry upland wooded areas, upland sandstone outcrops, rarely on rich woodland slopes and ravines. Frequent in most parts of Missouri, but absent from the northwestern and southeastern lowland sections.

Ranges from Massachusetts and New York to Michigan and Iowa, south to Virginia, Mississippi, Arkansas, and Texas.

Section 22. **Hirtae**

78. ***Carex lanuginosa*** Michx. Map 520
Carex lasiocarpa Ehrh. var. *latifolia* (Boeckl.) Gl.
[BB]
Flowers late April-July.

Occurs most commonly in wet meadows and river bottom prairies of open valleys and alluvial soils, also in swales of upland prairies, calcareous spring-fed

swampy meadows, and more rarely in wooded swamps. Found throughout the state, but most common in the northern half; absent from the southeastern lowland section and from some parts of the Ozarks.

Ranges from Quebec to British Columbia, south to Virginia, Tennessee, Arkansas, Oklahoma, Texas, New Mexico, Arizona, and California.

PLATE NO. 92

523 *Carex Joori*524 • *Carex Buxbaumii* f. *Buxbaumii*
524 □ *Carex Buxbaumii* f. *dilutior*525 *Carex aquatilis* var. *altior*Section 23. **Anomalae**79. ***Carex scabrata*** Schwein.

Flowers June–August.

Known only from a single collection from southwestern Missouri in Greene County (Springfield, July

Map 521

3, 1889, *S. Weller* in the herbarium of Drury College).

Ranges from Nova Scotia and Quebec to Ontario and Michigan, south to South Carolina, Ohio, Tennessee, and Missouri.

Section 24. **Shortianae**80. ***Carex Shortiana*** Dewey

Flowers early May–early July.

Frequents prairie swales, wet river bottom prairies, wet open valleys, borders of ponds, open swamps, and ditches, calcareous spring-fed swampy meadows, wooded swamps and flood plain forests, rich woods usually at the base of slopes, or in ravines and wooded valleys. Common in most parts of the state; apparently absent from extreme northwestern Missouri, most of the lowlands of the southeastern section, and from most parts of the southern Ozarks.

Ranges from Pennsylvania, Ontario to Iowa, south to West Virginia, Tennessee, Missouri, and Oklahoma.

Map 522

Occurs in low wet or alluvial woods and wet margins of upland sink-hole ponds. Found in Missouri at four widely scattered stations in Adair (*Steyermark 79705*), St. Louis (*Letterman*), Howell (*Steyermark 78724*), and Barton (*Palmer 53821*) counties. Known elsewhere only from Indiana.

Originally described from Indiana as a hybrid between *C. Shortiana* and *C. typhina*. At the Missouri stations encountered it has been found growing with *C. Shortiana* and *C. typhina* as well as with *C. squarrosa*, or with *C. Shortiana* and *C. squarrosa*. Probably future exploration will reveal many more stations for this hybrid which has thicker spikes (7–8 mm. thick) and longer beaks (1–1.5 mm. long) of the perigynia than those of *C. Shortiana*, the parent it most resembles. It will be interesting to learn whether *C. typhina* or *C. squarrosa* proves to be the commoner of the other one of the presumed parents of *C. × Deamii*.

80a. ***Carex × Deamii*** F. J. Herm.

Map 522

Carex Shortiana Dew. × *Carex typhina* Michx. and possibly *Carex squarrosa* L.

Flowers late May–September.

Section 25. **Pendulinae**81. ***Carex Joori*** Bailey

Flowers August–October.

Known only from low wet woods in the southeastern Missouri lowlands from Dunklin County (Campbell, September 12, 1910, *Bush 6327* and

Map 523

6327A).

Ranges from Florida to Texas, north to Virginia and Maryland, and in the interior to Tennessee and southeastern Missouri.

PLATE NO. 93

526 *Carex nebraskensis*527 *Carex Haydenii*528 *Carex Emoryi*Section 26. **Atratae**82. ***Carex Buxbaumii* Wahl.**

Map 524

Flowers late April–July.

Two variations occur in Missouri:

Scales of pistillate flowers purple-black, brown, or blackish-brown. 82a. *C. BUXBAUMII* f. *BUXBAUMII*
Scales of pistillate flowers whitish or pale brown

82b. *C. BUXBAUMII* f. *DILUTOR*82a. ***Carex Buxbaumii* f. *Buxbaumii*** Map 524*Carex Buxbaumii* Wahl. [G, BB, P & S]

Occurs in prairie swales of upland prairie along railroads, in wet river bottom prairie and alluvial meadows, and swampy woods. Rare and scattered in northern Missouri, where known from Marion (prairie between Monroe City and Hunnewell, May 28, 1934, *Steyermark* 8315), Linn (bottom prairie, valley of Locust Creek, Pershing State Park, June 26, 1941, *Steyermark* 40432), and Clinton counties, and in the lowlands of southeastern Missouri where known from Butler County (swamps, May 1, 1905, *Bush* 2663).

This species forms large colonies and clumps from

the long horizontal stolons. The whitish, nearly nerveless perigynia, narrow pale green or glaucous leaves, and dark red-purple base of the plant are additional recognition characters of this distinct species. While it bears a superficial resemblance to *C. Bushii*, the two are immediately distinguished in the field by the completely glabrous leaf-sheaths and blades of *C. Buxbaumii*.

82b. ***Carex Buxbaumii* f. *dilutor* Kükenth.**

Map 524

Known only from a calcareous, spring-fed, swampy meadow in the southeastern Ozark region from Reynolds County (along West Fork of Black River, T33N, R3W, sect. 23 and northeast sect. 26, 3–3½ mi. northwest of Greeley, July 6, 1951, *Steyermark* 71984).

Dr. Hermann believes that the pale color of the pistillate scales is the result of bleaching with age. If this is true, it is probable that no definite name should be given this form (Rh. 57: 312. 1955).

Section 27. **Acutae**83. ***Carex aquatilis* Wahlenb. var. *altior* (Rydb.)**

Fern.

Map 525

Carex aquatilis Wahl. in part [BB]*Carex substricta* (Kükenth.) Mackenz.*Carex aquatilis* var. *substricta* Kükenth. [Deam]

Flowers June–August.

Known only in the southeastern Ozark section from Carter County (alluvial banks of Ten Mile Creek, T26N, R3E, sect. 36, July 13, 1936, *Steyermark* 11735).

Ranges from Newfoundland and Quebec to British

Columbia, south to New Jersey, New York, Ohio, Indiana, Wisconsin, Missouri, Nebraska, Colorado, and Oregon.

This is apparently one of the Pleistocene relict species of a more boreal flora which has survived in an isolated sector of the Ozarks.

84. ***Carex nebraskensis* Dewey**

Map 526

Flowers May–July.

Introduced along railroad tracks in St. Louis County (north St. Louis, freight yard of Burlington

PLATE NO. 94

2

Railroad, north of Carrie Avenue, along the fifth track counted from east, June 15, 1957, *Muehlenbach 1199*).

Ranges from western Kansas and South Dakota to British Columbia, south to New Mexico and California; introduced in Missouri.

Dr. F. J. Hermann, *Carex* authority, has identified this specimen.

The plants have long creeping rootstocks with large blackish-brown scales. The leaves on the Missouri material are 3 dm. long, 3.5–5 mm. long, and are longer than the flowering culms which are 2.1–2.5 dm. tall. The pistillate spikes are on short to long slender peduncles which may attain 5 cm. in length. The lowest peduncles are sometimes drooping, but most are erect. The 2–5 pistillate spikes are cylindrical, 2–2.5 cm. long, 6–7 mm. thick in Missouri material. The pistillate scales are lanceolate, brown-purple or dark brown with a pale green or buff-nerved stripe down the middle, tapering into a slender, somewhat rigid cusp or awn 1–1.5 mm. long. The pistillate scales equal to slightly exceed the perigynia which are straw-colored or buff, sometimes speckled with maroon-red near the summit, and strongly nerved on the faces. In the Missouri specimen the perigynia are 2.7–3 mm. long, 1.6–1.8 mm. wide (perigynia up to 3.5 mm. long are described in Rydberg's *Flora of the Prairies and Plains*). The achenes have a hooked or bent style.

This species differs from *C. crinita*, with which it might at first be confused, by the mostly erect pistillate spikes, the bidentate beak of the strongly ribbed perigynia, and the uniformly short-awned or short-cuspidate instead of usually long-awned perigynia.

85. ***Carex Haydenii*** Dew. Map 527
Flowers May–July.

Occurs in wet river bottom prairies and along streams. Infrequent in northern and central Missouri, mostly in the northwestern third of the state.

Ranges from New Brunswick and Ontario to Minnesota, south to New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Missouri, and Nebraska.

Often confused with *C. Emoryi*, a much more common species in the state.

86. ***Carex Emoryi*** Dew. Map 528
Carex stricta [of P & S], not Lam.
Carex stricta var. *elongata* (Boeckl.) Gl. [BB]
Flowers late April–June.

Commonly occurring along banks of streams in the Ozark section or in wet river bottom prairies and

valleys in northern and central Missouri. Widespread in the state, most common in northern Missouri and the Ozark section; apparently absent from the southeastern lowland section, and rare in the unglaciated prairie region.

Ranges from Florida to Texas and New Mexico, north to New Jersey, New York, Ohio, Indiana, Wisconsin, Minnesota, Manitoba, and Colorado.

Along the alluvial banks and among the rocky limestone boulders at the base of bluffs of Ozark streams, this species is conspicuous with its large colonies and masses of long, narrow, dark green leaves. The perigynia start falling from the spikes after the middle of July, so that fruiting material for identification must be collected usually before this time. Once, however, acquaintance has been made in recognizing this species in fruiting condition, it becomes easy to identify it in repeated encounters by habitat, habit, and foliage characters.

Specimens included by Palmer and Steyermark in their *Annotated Catalogue* under *Carex stricta* Lam. are referred to *C. Emoryi* in the present work. The specimen from Greene County (Springfield, June 4, 1889, S. Weller in the herbarium of Drury College) was labelled *C. stricta* var. *angustata* Gray.

87. ***Carex stricta*** Lam. var. ***strictior*** (Dew.)
Carey Tussock Sedge Map 529
Carex stricta var. *stricta* in part [BB]
Flowers May–July.

Known only from calcareous, spring-fed, swampy meadows of the southeastern Ozarks in Maries (valley of Little Tavern Creek, along highway 42, T40N, R11W, W sect. 33, 11 mi. south of Meta, July 6, 1952, *Steyermark 73686*) and Reynolds (along Bee Fork, T32N, R2W, sect. 23, 4½ mi. southeast of Bunker, May 29, 1951, *Steyermark 71303*; and July 7, 1951, *Steyermark 72032*) counties.

Ranges from Quebec to Ontario and Minnesota, south to North Carolina, Tennessee, and Missouri.

Like several other more northern species of *Carex*, this is another one of the elements of the relict Pleistocene flora which has managed to survive in the swampy meadows of the Ozark region.

At the Maries County locality this sedge was growing with and under the tall culms of the rare and local *C. trichocarpa*.

The previous records for *C. stricta* in Missouri, originally included in Palmer and Steyermark's *Annotated Catalogue*, are now referred to *C. Emoryi*.

PLATE NO. 95

529 *Carex stricta* var. *strictior*530 *Carex torta*531 • *Carex crinita* var. *crinita*531 □ *Carex crinita* var. *brevicrinis*

The formation of dense cushions or tussocks of long leaves is very characteristic of the varieties of *C. stricta*.

88. ***Carex torta* Boott**
Flowers mid-April–July.

Map 530

Frequents banks of small running streams and spring branches. Found throughout the eastern Ozark section west to Dent, Douglas, and Howell counties.

Ranges from Quebec and Nova Scotia to Minnesota, south to Georgia, Tennessee, and Arkansas.

Section 28. **Cryptocarpae**

89. ***Carex crinita* Lam.** Fringed Sedge Map 531
Flowers May–July.

Frequents spring branches, fast-running streams, spring-fed calcareous swampy meadows, margins of ponds, wet river bottom prairies, prairie swales, and sloughs. Two varieties are represented in Missouri:

Pistillate spikes rarely with staminate flowers at summit of spike; awns at the tip of the lower scales 2–4 times as long as the perigynia, upper scales longer than perigynia; perigynia 2–3 (–3.5) mm. long, 1–2 mm. thick. 89a. *C. CRINITA* var. *CRINITA*

Pistillate spikes frequently with staminate flowers at summit; awns at the tip of the lower scales equal to or 2 times as long as the perigynia, upper scales about equaling or slightly longer than perigynia; perigynia 3–4 mm. long, 2–3 mm. thick.

89b. *C. CRINITA* var. *BREVICRINIS*

- 89a. ***Carex crinita* var. *crinita***
Carex crinita Lam. [G, P & S]

Map 531

The commoner variety in the state, in southern and central Missouri north to Shelby, Boone, and Caldwell counties.

Ranges from Newfoundland to Manitoba, south to Georgia, Tennessee, and Missouri.

- 89b. ***Carex crinita* var. *brevicrinis* Fern.**

Map 531

Carex crinita var. *crinita* in part [BB]

Carex crinita var. *gynandra* [of P & S], not (Schwein.) Schwein. & Torr.

Scattered in southern and central Missouri.

Ranges from Florida to Texas, north near or along the Coastal Plain to Massachusetts, inland north to Kentucky, Tennessee, and Missouri.

The above varieties grade into one another. They are not recognized as distinct by Gleason.

Section 29. **Pseudo-Cypereae**

90. ***Carex hystericina* Muhl.** Map 532
Flowers May–July.

Most commonly occurring in spring-fed, calcareous, swampy meadows and wet open places. Rare in southern and central Missouri, north to St. Louis, Saline, and Jackson counties.

Ranges from Quebec to Alberta and Washington, south to Virginia, Tennessee, Missouri, Oklahoma, Texas, New Mexico, Arizona, and California.

91. ***Carex comosa* Boott**
Flowers July–late August.

Map 533

PLATE NO. 96

532 *Carex hystericina*533 *Carex comosa*534 *Carex lurida*

Occurs in upland sink-hole ponds in the southeastern Ozarks in Shannon and Oregon counties, in swampy ground in the southeastern lowland section in Butler and Dunklin counties, and along margins of oxbow lakes along the Missouri River in west-central Missouri in Platte County (Iatan Pond, $\frac{1}{2}$ mile north of Iatan, September 5, 1934, *Steyermark 15244*).

Ranges from Florida to Louisiana, north to Nova Scotia, Maine, Quebec, Ontario, Michigan, Wisconsin, Minnesota, and Nebraska; also from Idaho and Washington to California.

92. ***Carex lurida* Wahlenb.** Map 534

Flowers early May–September.

Occurs commonly along spring branches, small streams, borders of ponds in valleys, spring-fed calcareous swampy meadows, prairie swales, wet river bottom prairie, and wet open places in valleys. Common throughout southern and central Missouri north to Jackson, Saline, and Boone counties, northeast to Marion County.

Ranges from Florida to Texas and Mexico, north to Nova Scotia, Maine, Quebec, Ontario, and Minnesota.

This is placed in section *Vesicariae* in the works of Gleason and Deam.

93. ***Carex Schweinitzii* Dew.** Map 535

Flowers May–July.

Known only from three collections, all from St. Louis County (June, 1883, *Letterman 21* in New York Botanical Garden Herbarium; west of engine house of Baden freight yard of Mo.-Kan.-Top. R. R., St. Louis, May 4, 1957, *Muehlenbach 1136*; freight yard Carrie Ave. of Rock Island R. R. on large free place south of Carrie Ave., St. Louis, May 7, 1955, *Muehlenbach & Kramer 548*).

Ranges from Vermont to Ontario and Michigan, south to New Jersey, North Carolina, Tennessee, and Missouri.

This is one of the rarest carices in Missouri. The *Muehlenbach 1136* collection was found among bushes in the low area in the north part of St. Louis adjacent to the Mississippi River.

Carex *Schweinitzii* is placed in section *Vesicariae* in the work of Gleason.

Section 30. **Paludosae**

94. ***Carex lacustris* Willd.** Map 536

Carex lacustris var. *lacustris* [BB]

Carex riparia Curtis var. *lacustris* (Willd.) Kükenth.

Flowers May–July.

Occurs in wet river bottom prairies, prairie swales, and wet alluvial soils.

Known only from northern Missouri in Mercer, Linn, and Caldwell counties.

Ranges from Quebec to Manitoba, south to Virginia, Ohio, Indiana, Illinois, Missouri, and South Dakota; also Idaho.

Previous records attributed to this species from other counties in Missouri are now referred to *C. hyalinolepis*.

95. ***Carex hyalinolepis* Steud.** Map 537

Carex lacustris var. *laxiflora* Dew. [BB]

Flowers late April–July.

Frequents bottom prairies, wet meadows, swampy woods, open wet swales in alluvial flood plain soils especially along the larger rivers, borders of sloughs, open swamps, ditches, oxbow lakes in the valleys of

4

PLATE NO. 97

535 *Carex Schweinitzii*536 *Carex lacustris*537 • *Carex hyalinolepis*
537 □ *Carex subimpressa*

rivers, and rarely along margins of upland sink-hole ponds in the Ozarks. Found mostly in eastern, central, and western Missouri, following principally the Mississippi, Missouri, St. Francis, Grand, and Osage rivers and some of their main tributaries; absent from most of the Ozark section and the tiers of counties in extreme northern Missouri; in the lowlands of southeastern Missouri it often inhabits bald cypress (*Taxodium*) swamps.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Ontario, Ohio, Michigan, Wisconsin, Iowa, and Nebraska.

This species forms dense stands of glaucous or silvery-green leaves and culms, and grows frequently in depressions in flood plains or sloughs where it remains with its culms in water for indefinite prolonged periods of time. It often frequents the wet alluvial soils where forests of silver maple and cottonwood dominate, becoming a dominant ground cover in such areas, and also is found in thickets with buttonbush.

95a. ***Carex* × *subimpressa*** Clokey Map 537
Carex lanuginosa × *Carex hyalinolepis*
Flowers May–June.

Occurs in wet meadows and swampy ground of alluvial flood plain. Known from northern and central Missouri in Bates, Clinton (open swales of meadow in draw along highway C, T54N, R31W, sect. 6, 2¾ mi. southeast of Plattsburg, May 23, 1957, *Steyermark* 84652), and Lewis (swamp in alluvial bottoms of Mississippi River along highway 61, 2 mi. north of Canton, May 14, 1939, *Steyermark* 26489) counties.

Known only from Indiana, Illinois, and Missouri.

This is a supposed hybrid between *C. lanuginosa* and

C. hyalinolepis. It has a more robust appearance than *C. lanuginosa*, but is less robust than *C. hyalinolepis*. The grass-green leaves are similar in color to those of *C. lanuginosa*. At the Lewis County station, only *C. lanuginosa* and *C. vesicaria* were in the immediate neighborhood of the hybrid plant.

96. ***Carex atherodes*** Spreng. Map 538
Flowers May–July.

Occurs in rich swampy woods and in sandy wet swales in northern and west-central Missouri, where it is known from Mercer (rich swampy woods, 4½ mi. northeast of Saline, May 27, 1934, *Steyermark* 9505) and Jackson (sandy swales, Courtney, May 27, 1916, *Bush* 7725 and 7725a) counties.

Ranges from Ontario to Yukon, south to New York, Ohio, Indiana, Wisconsin, Missouri, Nebraska, Colorado, Utah, and Oregon; also in Maine.

97. ***Carex laeviconica*** Dew. Map 539
Flowers late April–July.

Occurs in wooded swamps and in wet soils of alluvial flood plain forests, also along streams, in wet low bottom prairies, wet open valleys, and prairie swales. Infrequent in northern and central Missouri, south from Clark to Livingston, Cooper, and Jackson counties.

Ranges from Manitoba and Saskatchewan, south to Illinois, Missouri, Kansas, and Montana.

98. ***Carex trichocarpa*** Muhl. Map 540
Flowers June–August.

Found in spring-fed, calcareous, swampy meadows in valleys along small streams in the eastern Ozarks in Maries (valley of Little Tavern Creek, along highway 42, T40N, R11W, west part sect. 33, 11 mi. south of

PLATE NO. 98

538 *Carex atherodes*539 *Carex laeviconica*540 *Carex trichocarpa*

Meta, July 6, 1952, *Steyermark 73685*) and Reynolds (along West Fork of Black River, T33N, R3W, sect. 23 and NE sect. 26, 3–3½ mi. northwest of Greeley, July 6, 1951, *Steyermark 71977*) counties.

Ranges from Quebec and Vermont to Ontario and

Minnesota, south to Delaware, Ohio, Indiana, Illinois, and Missouri.

Carex trichocarpa attains heights of 1.3 meters, and forms large dense leafy colonies. It is the tallest-growing and most stately species of *Carex* in Missouri.

Section 31. **Squarrosae**

99. ***Carex Frankii* Kunth**

Map 541

Flowers late May–September.

Occurs in moist soil or gravel bars along small streams and spring branches, margins of ponds, spring-fed calcareous swampy meadows, low wet woods or alluvial flood plain forests, wet low river bottom prairie, prairie swales, wet open valleys, and meadows. Abundant and widespread in the state, especially common in the Ozark section, but absent in the northwestern and extreme north-central sections of the state.

Ranges from Georgia to Texas, north to New York, Pennsylvania, Ohio, Michigan, Illinois, Missouri, and Kansas.

Easily recognized by the long leaflike bracts, which are 2–4 times as long as the inflorescence, by the very long rough awns of the pistillate scales, and by the widely spreading perigynia which are broadest near the summit of their bodies.

100. ***Carex squarrosa* L.**

Map 542

Flowers late April–September.

Most commonly found in wooded swamps, low wet woods, or forested alluvial flood plain, sometimes also in open wet swales in river valleys and prairies, and low swampy meadows. Common in the eastern half

of the state and in parts of western Missouri, following generally the larger streams; apparently absent from the extreme northwestern, southwestern, and parts of west-central Missouri.

Ranges from Connecticut to Ontario, Minnesota, and Nebraska, south to North Carolina, Tennessee, and Arkansas.

The spikes are broadly elliptical-oblong or short-cylindric. A misleading illustration in *Gray's Manual*, 8th edition, p. 371, shows the spikes globose or subglobose, a shape not seen in the average Missouri *C. squarrosa*.

101. ***Carex typhina* Michx.**

Map 543

Flowers late April–September.

Frequents swampy or low wet woods, forested alluvial flood plain, low rich wooded valleys, wet river bottom prairies, prairie swales, and wet open valleys. Mostly found in the eastern half of the state, where it follows generally the larger streams and their tributaries, locally west to Jackson, Vernon, and Barton counties south of the Missouri River, and north of the Missouri River west to Mercer, Grundy, Linn, Chariton, and Boone counties; apparently absent from most of the Ozark, unglaciated prairie, and northwestern sectors of the state.

PLATE NO. 99

541 *Carex frankii*542 *Carex squarrosa*543 *Carex typhina*Section 32. **Vesicariae**102. ***Carex vesicaria* L. var. *monile* (Tuckerm.)**

Fern.

Map 544

Carex vesicaria in part [BB, P & S], not L.

Flowers May–August.

Most commonly found in low wet river bottom prairie, prairie swales, swampy open ground in valleys, and swampy woods or forested alluvial flood plain. Rare in northern and central Missouri, south to St. Louis, Saline, and Jackson counties.

Ranges from Quebec and Ontario, south to Delaware, Pennsylvania, Ohio, Indiana, Illinois, and Missouri.

The more northern ranging typical *C. vesicaria* var. *vesicaria* has somewhat longer perigynia (7–9 mm. long instead of 5–8 mm.), with more slender, ovoid-conic bodies $1\frac{1}{3}$ – $1\frac{1}{2}$ as thick as long, tapering more gradually to a beak, and the leaf-blades average broader (4–7 mm. instead of 2–5 mm. wide).

Like *C. trichocarpa*, this species attains considerable height, up to 1 meter tall, and is one of the tallest of the *Carex* species in Missouri. It usually forms dense tussocks or clumps. The long leafy bracts of the inflorescence usually greatly extend above the inflorescence.

Section 33. **Lupulinae**103. ***Carex Grayii* Carey**

Map 545

Flowers May–October.

Most commonly occurs in swampy or low wet woods and forested alluvial flood plain, where it is found along some of the larger rivers and their tributaries.

Missouri material may be divided into 2 varieties:

Perigynia glabrous (without hairs) . . . 103a. *C. GRAYII*
var. *GRAYII*

Perigynia with short hairs . . . 103b. *C. GRAYII*
var. *HISPIDULA*

103a. ***Carex Grayii* var. *Grayii***

Map 545

Carex Grayii Carey [G]*Carex Grayii* in part [BB]*Carex Asa-Grayii* Bailey in part [P & S]

Found in parts of eastern, northern, and central Missouri along the larger streams and tributaries; absent from the Ozark section. Less common than var. *hispidula*.

Ranges from Quebec to Iowa, south to New Jersey, Pennsylvania, Ohio, Indiana, Illinois, and Arkansas.

103b. ***Carex Grayii* var. *hispidula* Gray** Map 545*Carex Asa-Grayii* Bailey in part [P & S]*Carex Grayii* in part [BB]

The commoner variety in Missouri and more frequent in some of the counties of the western sector south of the Missouri River.

Ranges from Connecticut and New York to Ohio, Michigan, Indiana, and Illinois, south to Georgia, Mississippi, and Missouri.

There is considerable doubt as to whether var. *hispidula* should merit recognized varietal status, and some authors include it with typical *C. Grayii*. According to Dr. Hermann (Deam's *Flora of Indiana*, p. 270. 1940), observations made by J. K. Underwood of the University of Tennessee Agricultural Experiment Station indicate that the glabrous and pubescent perigynia are variations or seasonal fluctuations which may be found even on the same plant. However, until careful studies have been made throughout the range of *C. Grayii*, it seems preferable to give tentative recognized status to var. *hispidula*.

1

2

3

4

544 *Carex vesticaria* var. *montie*545 • *Carex Grayii* var. *Grayii*
545 □ *Carex Grayii* var. *blapidula*546 *Carex intumescens* var. *intumescens*

Although the usual shape of the pistillate spikes is of a globose type, occasional plants are found (Palmer 2196 from Quaker Mill, Jasper Co., for example) in which the spikes are longer than broad.

104. ***Carex intumescens* Rudge var. *intumescens*** Map 546

Carex intumescens Rudge [G, BB in part, P & S]
Flowers late April–July.

Occurs in low wet woods and wooded swamps or forested alluvial flood plain. Known only from the lowlands of southeastern Missouri north to Cape Girardeau and Wayne counties, and west to Ripley County, where it inhabits margins of upland sink-hole ponds (Steyermark 66114).

Ranges from Florida to Texas, north to Nova Scotia, Maine, Quebec, New York, Ontario, Michigan, and Wisconsin.

The more northern var. *Fernaldii* Bailey has narrower perigynia (3.5–5 mm. instead of 5–8 mm. thick) which are 1/4–1/3 instead of nearly 1/2 as broad as long.

105. ***Carex louisianica* Bailey** Map 547
Flowers late April–August.

Occurs in low wet woods and wooded swamps or forested alluvial flood plain. Known from the lowlands of southeastern Missouri north to Cape Girardeau and Wayne counties, and west to Butler County, locally north in St. Louis County.

Ranges from Florida to Texas, north to New Jersey, Kentucky, Indiana, and Missouri.

106. ***Carex lupulina* Muhl. Hop Sedge** Map 548
Flowers early May–September.

Occurs in low wet woods, forested alluvial flood plain, borders of upland sink-hole and other ponds, open wet swales in valleys, wet low river bottom prairies, prairie swales, and along ditches. Widespread

and common in Missouri, but not recorded from some of the western Ozark and southwestern counties, and apparently absent from extreme northwestern Missouri.

Missouri material is represented by 2 varieties:

Pistillate spikes without a peduncle (stalk) or nearly so, mostly close to one another . . .

106a. ***C. LUPULINA* var. *LUPULINA***
Pistillate spikes usually with a definite peduncle, rather distant and well apart from one another

106b. ***C. LUPULINA* var. *PEDUNCULATA***

106a. ***Carex lupulina* var. *lupulina*** Map 548
Carex lupulina Muhl. [G, P & S in part, BB in part]

This is the more common variety in Missouri.

Ranges from Florida to Texas, north to Nova Scotia, Maine, Quebec, New York, Ontario, Michigan, Wisconsin, and Minnesota.

106b. ***Carex lupulina* var. *pedunculata* Gray** Map 548

Carex lupulina Muhl. in part [BB, P & S]

This variety is scattered in parts of southern and central Missouri northeast to Marion County, and is less common than var. *lupulina*.

Ranges from Quebec to Ontario, south to Georgia, Illinois, and Missouri.

This variety is not recognized by some authors (Gleason, Deam), and only intensive future studies will reveal the relative significance of the peduncled pistillate spikes.

107. ***Carex lupuliformis* Sartwell** Map 549
Flowers early July–September.

Occurs in swamps, low wet woods and margins of ponds in river bottom or lowland areas. Rare and scattered in eastern and northern Missouri, where known from Putnam, Livingston, Montgomery, St. Louis, Stoddard, Butler, and Ripley counties.

547 *Carex louisianica*

548 • *Carex lupulina* var. *lupulina* (Hop Sedge)
548 □ *Carex lupulina* var. *pedunculata*

549 *Carex lupuliformis*

Ranges from Vermont to Minnesota, south to Virginia, Kentucky, Louisiana, and Texas.

108. **Carex gigantea** Rudge: Map 550
Flowers late May–September.

Occurs in low wet woods, wooded swamps, or forested alluvial flood plain. Known only from the lowlands of southeastern Missouri north to Scott, Stoddard, and Wayne counties, west to Ripley County.

Ranges from Florida to Texas, north to Delaware, Indiana, Kentucky, and southeastern Missouri.

Excluded species

Carex cephaloidea Dew.
Included in Palmer and Steyermark’s *Annotated*

Catalogue, the collections from St. Louis (Prospect Hill, St. Louis, *Glatfelter*; Crescent, *Eggert*) and Jackson counties, upon which the species was included, are now referred to *C. aggregata* Mackenz.

Carex hormathodes Fern.

The Jasper County collection, which formed the basis for the inclusion of this species in Palmer and Steyermark’s *Annotated Catalogue* is now referred to *C. Bicknellii*.

Carex laxiflora Lam.

Carex anceps Muhl., included by Palmer and Steyermark in their *Annotated Catalogue* on the basis of several collections from western Missouri, is a synonym of *C. laxiflora* Lam. The records constituting the basis for this report are now referred to *C. blanda* Dew.

Order **ARALES**

Fam. **Araceae** (Arum Family)

- a. Leaf-blades sword-shaped, iris-like, long and narrow; leaves and rootstocks pleasantly fragrant when crushed. 3. **ACORUS**
- a. Leaf-blades not sword-shaped, but of a broader type; leaves and underground parts not fragrant b
 - b. Leaves simple, the blades sagittate (arrowhead-shaped) 2. **PELTANDRA**
 - b. Leaves not simple, divided into 3 or 5–15 leaflets (divisions) 1. **ARISAEMA**

1. **Arisaema** Mart. Jack-in-the-Pulpit, Green Dragon

- Leaf-divisions (leaflets) 3 1. **A. ATORRUBENS**
- Leaf-divisions (leaflets) 5–15 2. **A. DRACONTIUM**

1. **Arisaema atorrubens** (Ait.) Blume
Jack-in-the-Pulpit, Indian Turnip Map 551
Flowers April–June.
Missouri material may be divided into 3 forms:

- a. Hoodlike flap of flower green only 1c. **A. ATORRUBENS** f. **VIRIDE**

- a. Hoodlike flap of flower entirely purple or purple to bronze with pale or greenish stripes b
 - b. Hoodlike flap entirely purple without any pale stripes. 1a. **A. ATORRUBENS** f. **ATORRUBENS**
 - b. Hoodlike flap purple or bronze with pale or greenish stripes 1b. **A. ATORRUBENS** f. **ZEBRINUM**

550 *Carex gigantea*

551 • *Arisaema atrorubens* f. *atrorubens* (Jack-in-the-Pulpit) 552 *Arisaema Dracontium* (Green Dragon)
 551 □ *Arisaema atrorubens* f. *viride*
 551 x *Arisaema atrorubens* f. *zebrinum*

1a. ***Arisaema atrorubens* f. *atrorubens***

Map 551

Arisaema triphyllum [of P & S], not (L.) Schott
Arisaema triphyllum var. *triphyllum* [BB]

Occurs in rich, level or hilly, rocky or nonrocky wooded areas or in low bottom thickets.

Throughout Missouri, doubtless in every county.

Ranges from New Brunswick and Quebec to Manitoba, south to South Carolina, Tennessee, Arkansas, and Kansas.

1b. ***Arisaema atrorubens* f. *zebrinum*** (Sims)

Fern.

Map 551

Throughout the range of *A. atrorubens*.

1c. ***Arisaema atrorubens* f. *viride*** (Engler) Fern.

Map 551

Throughout the range of *A. atrorubens*.

At first green, the fruiting head of fleshy, berrylike fruits finally becomes scarlet or orange-red, adding a striking color touch to the woodland floor in late summer and autumn.

The fresh rootstocks and leaves containing crystals of calcium oxalate may cause poisoning if large

amounts are eaten raw, and a few people develop a dermatitis after touching the plant. After being thoroughly dried (but not boiled), the round, solid underground starchy corm can be grated and made into a type of flour, and was so used by the Indians in eastern North America.

2. ***Arisaema Dracontium*** (L.) Schott

Green Dragon

Map 552

Flowers April–June.

Occurs in moist or rich, rocky or nonrocky woodland, usually in level ground, at the base of slopes, in ravines, or flood plain forest, mostly in wetter ground than that of the preceding species.

Occurs throughout Missouri, doubtless in every county.

Ranges from New Hampshire and Quebec to Ontario, Michigan, and Wisconsin, south to Florida and Texas.

The rounded solid starchy corm may be dried and used for a flour in the same manner as the preceding species. The berrylike fruits are of a similar color to those of the Indian Turnip.

2. ***Peltandra*** Raf. Arrow Arum

Peltandra virginica (L.) Schott & Endl.

Arrow Arum

Map 553

Flowers April–June.

Occurs in wet, mucky ground bordering sloughs and oxbow lakes of river bottoms.

Missouri material is represented by 2 forms:

Lobes at base of leaf-blade 3–7.5 cm. broad; main upper part of leaf-blade 8–18 cm. broad . . .

P. VIRGINICA f. *VIRGINICA*

Lobes at base of leaf-blade 1–3.5 cm. broad; main upper part of leaf-blade 3–12 cm. broad . . .

P. VIRGINICA f. *HASTIFOLIA*

Peltandra virginica* f. *virginica

Map 553

Very rare, known only from St. Charles, St. Louis, Jefferson, Cape Girardeau, and Wayne counties in eastern Missouri.

Ranges from Maine and Quebec to New York, Ontario, and Michigan, south to Florida and Texas.

PLATE NO. 101

553 • *Peltandra virginica* f. *virginica* (Arrow Arum)
553 □ *Peltandra virginica* f. *hastifolia*

554 *Acorus Calamus* (Sweet Flag)

555 *Spirodela polyrhiza* (Big Duckweed)

***Peltandra virginica* f. *hastifolia* Blake** Map 553

Known only from Dunklin County, southeastern Missouri.

Other leaf variations have been described and may eventually be found in the state.

In contrast to Indian Turnip or Green Dragon, the root is very large and perpendicular, and the green calla-lilylike spathe with paler margins surrounds the mass of tiny flowers which occur throughout the elongated spadix instead of just at its base as in

Arisaema. In the fruiting stage the berries are green or brownish in a thick fleshy head surrounded at the base by the thick spathe with a beaklike summit. Some of the North American Indians are reported to have eaten the berries, which, after boiling, are said to be somewhat sweet. A type of bread can be made from the seeds. The roots are stated to be poisonous when raw, but, after being cooked, can be used as a starchy vegetable, similar to potatoes in flavor.

***Acorus* L. Sweet Flag, Calamus**

***Acorus Calamus* L. Sweet Flag**

Map 554

Flowers May-July.

Occurs in wet meadows, swales of prairies, along spring branches, open wet ground, and along sloughs and ponds. Found throughout the state, although unrecorded from more than half the counties of the state.

Native of Europe; introduced in North America, where found from Nova Scotia to Montana and Oregon, south to Florida, Texas, and Colorado.

The plant usually occurs in large colonies, occu-

pying a continuous area. Sometimes entire stands are found with no flowers or fruit present.

The drug Calamus is made from the fragrant rootstock, in a powdered form being employed for toilet powders and in distilled form as an oil in perfumeries. It is also employed in flavorings and medicine. The spicy-peppery roots also are used as a candy, after having been boiled and sugared. The tender interior of the tip of the young leafy shoots in spring may be used fresh as a cold salad substitute.

Fam. Lemnaceae (Duckweed Family)

- a. No roots present b
- b. Plants 6-8 mm. long, many times longer than broad, linear, thin 4. WOLFFIELLA
- b. Plants at most 1.5 mm. long; only slightly longer than broad, or nearly as broad as long, oblong to ovoid, thickish 3. WOLFFIELLA
- a. Plants with 1 or more roots c
- c. Roots 2 to several to a plant; plant purplish-red underneath 1. SPIRODELA
- c. Roots 1 to a plant; plant green underneath 2. LEMNA

Plate no. 102. 1. *Spirodela polyrhiza*; a. $\times \frac{3}{4}$; b. $\times \frac{3}{4}$; c. $\times 4\frac{1}{2}$. 2. *Spirodela oligorhiza*; a. $\times \frac{3}{4}$; b. $\times 3\frac{3}{4}$; c. $\times 4\frac{1}{2}$. 3. *Lemna trisulca*; a. $\times \frac{3}{4}$; b. $\times \frac{3}{4}$; c. $\times 4$.

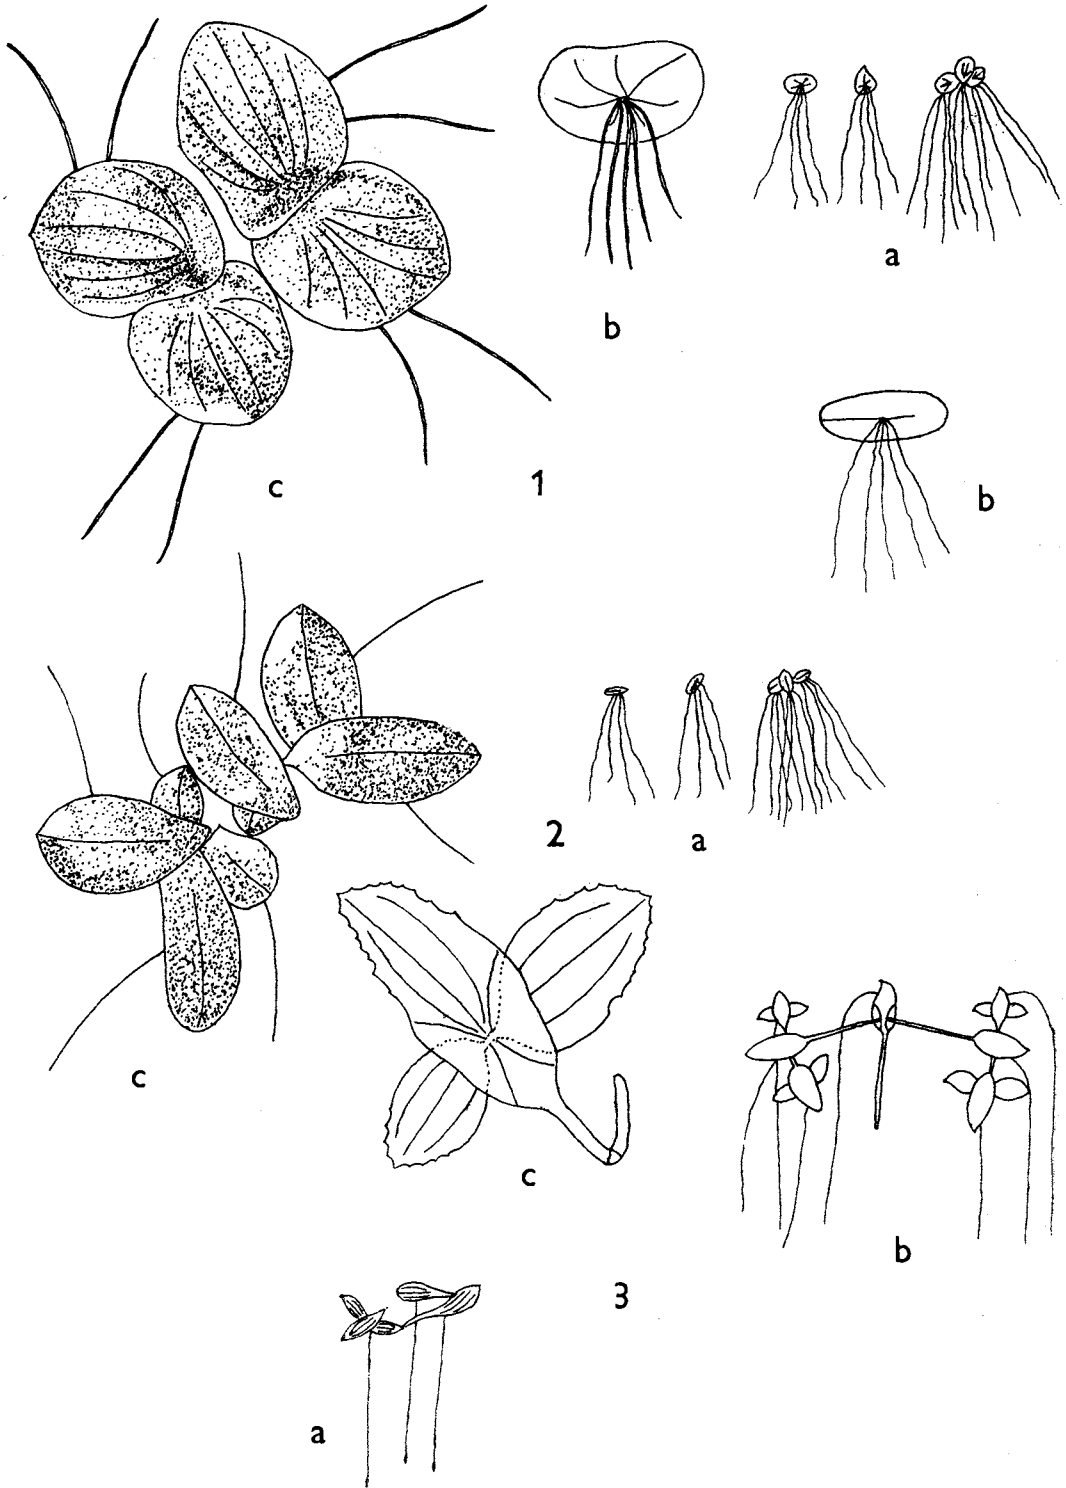

PLATE NO. 102

556 *Spirodela oligorhiza*557 *Lemna trisulca* (Star Duckweed)558 *Lemna minor* (Lesser Duckweed)

1. *Spirodela* Schleiden Big Duckweed

Plant more or less circular or broadly obovate, 3–8 mm. long, with 5–11 nerves and 6–18 roots. 1. *S. POLYRHIZA*
 Plant oblong or narrowly obovate, 2–4 mm. long, with 4–6 nerves and 2–3 (rarely –6) roots. 2. *S. OLIGORHIZA*

1. *Spirodela polyrhiza* (L.) Schleid.

Big Duckweed

Map 555

Occurs in sloughs, artificial and natural ponds, oxbow lakes of river bottoms, and sluggish margins of streams. Throughout Missouri.

Ranges from Nova Scotia, Ontario, Minnesota, Nebraska, and British Columbia, south to Florida, Texas, California, Mexico; also Central and South America, the West Indies, Europe, and Asia.

Recorded as being a good food for wildfowl.

2. *Spirodela oligorhiza* (Kurtz) Hegelm.

Map 556

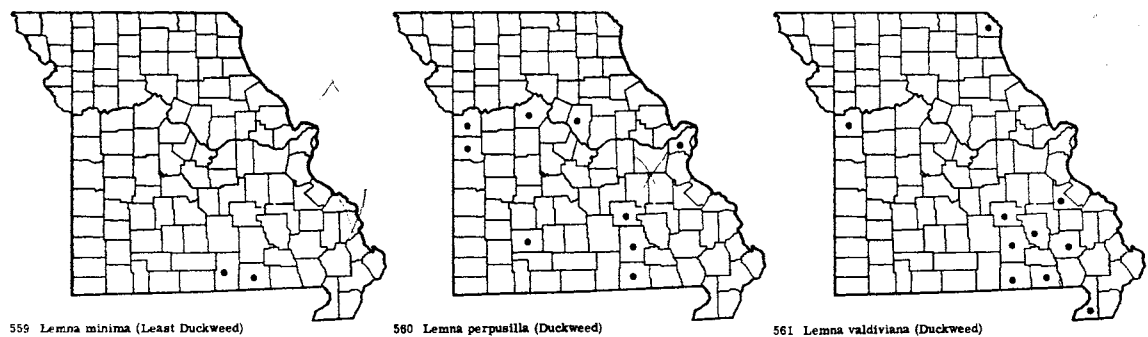

Known only from a slow-flowing stream in the wooded section of Swope Park, Kansas City, in Jackson County, where originally collected by Dr. A. C. Saeger on November 2, 1930, and from a goldfish pond in southwestern Missouri by Dr. F. H. Woods in September, 1932 (Bull. Torr. Bot. Club 61: 233–36. 1934).

Known in the United States only from Missouri. Ranges in warm and temperate areas of Australia, India, Java, Japan, and New Zealand.

2. *Lemna* L. Duckweed

With the exception of *Lemna trisulca*, a species usually submerged in the water and with long narrow stalked fronds, the remainder of the species are very difficult to separate from one another and usually require examination with either a high-powered or binocular microscope.

- a. Plants usually submerged, connected with one another by their narrowed and long-stalked bases, the green leafy joints 4–10 mm. long 1. *L. TRISULCA*
- a. Plants usually floating on the surface (at least during the spring, summer, and fall months), rounded at their base or not long-stalked, the green leafy joints 1.5–5 mm. long *b*
- b. The green joints of plant more or less symmetrical (the right half similar in shape and size to the left half) *c*
- c. Both upper and lower surface of green joints convex (sloping or curved to a higher center); joints with 3 weak nerves, with thickened margins 2. *L. MINOR*
- c. Lower surface of green joints flat; joints with 1 weak nerve, with thin margins. 3. *L. MINIMA*
- b. The green joints of plant not symmetrical (right and left halves not completely similar), one side or end shorter or more curved than the other *d*
- d. Joints with 3 faint or recognizable nerves, nearly as broad as long or at most $1\frac{3}{4}$ times as long as broad, 1.2–2.5 mm. wide, with curved or rounded sides, obovate or oblong-obovate 4. *L. PERPUSILLA*
- d. Joints with 1 faint nerve or nerveless, 2–3 times as long as broad, mainly 0.5–1.5 mm. wide, with nearly parallel sides, narrowly oblong or narrowly elliptic 5. *L. VALDIVIANA*

1. **Lemna trisulca** L. Star Duckweed Map 557
Also called Ivy-leaved Duckweed and Submerged Duckweed.

Rare, known only from a few cold fresh-water springs in the southeastern Ozarks (Ripley, Oregon, and Shannon counties), and from cold spring-fed ponds or lakes in Jackson and Mercer counties of northern and western Missouri.

Ranges from Nova Scotia and Ontario to British Columbia, south to Florida, Texas, California, and Mexico; also in the Old World.

Occasionally plants are found lacking roots. The plants form large tangled masses in the water and are of usually a dark blue-green color, as contrasted with a pale to grass-green shade of the other species of Lemna. They are often an important wildfowl food as well as eaten by small aquatic animals.

2. **Lemna minor** L. Lesser Duckweed Map 558
Found in sloughs, ponds, and slow-flowing streams. Scattered throughout Missouri.

Ranges from South America, Central America, and Mexico, north throughout the United States north to Labrador, Ontario, and British Columbia; also in the Old World.

This species is an important food of wildfowl, and is eaten also by muskrats and small aquatic animals.

3. **Lemna minima** Philippi Least Duckweed Map 559

Known only from upland natural sink-hole ponds in Oregon (Tupelo Gum Pond, Irish Wilderness, sect. 4. May 23, 1938, *Steyermark 5365*) and Howell (be-

tween Moody and South Fork, sect. 7, 2 mi. south of South Fork, April 28, 1938, *Steyermark 5222*) counties in the southern Ozark region.

Ranges from South America, Central America, and Mexico, north to Ohio, Indiana, Missouri, Minnesota, Wyoming, and California.

The above-cited specimens were determined by Lawrence E. Hicks, a student of the *Lemnaceae*.

4. **Lemna perpusilla** Torr. Duckweed Map 560
Lemna perpusilla var. *trinervis* Austin [P & S]

Occurs in sloughs, ponds, and stagnant water.

Scattered in parts of southern and central Missouri. Ranges from Florida, Arkansas, and Oklahoma, north to Massachusetts, New York, Ohio, Indiana, Illinois, Wisconsin, Minnesota, and North Dakota. Also in South America.

The tip of the root in this species is pointed, whereas in *L. minor* it is rounded. The root-sheath in *L. perpusilla* is furnished with lateral wing appendages, and in *L. valdiviana* the appendages are absent.

This species is eaten by ducks.

5. **Lemna valdiviana** Phil. Duckweed Map 561

Occurs in sloughs, ponds, and stagnant water, sometimes in organic debris along the margins of sink-hole ponds. Scattered in the state, mostly in the southeastern quarter, locally north in Clark County and west in Jackson County.

Ranges from South and Central America, the West Indies, and Mexico, north into the United States to Massachusetts, New York, Ohio, Indiana, Michigan, Wisconsin, Wyoming, Nevada, and Oregon.

This species is recorded as being eaten by ducks.

3. **Wolffia** Horkel Water-meal

The species of this genus are considered to be the smallest flowering plants known and are considered to provide good food and cover for fish. As in *Lemna*, the species are very difficult to distinguish and must be studied under a high-powered or binocular microscope.

562 *Wolffia columbiana* (Water-meal)563 *Wolffia punctata* (Water-meal)564 *Wolffia papulifera* (Water-meal)

- a. Plants without dots, the upper surface convex (sloping or curved to a higher center); shape of plant mainly globose or nearly circular in outline; upper surface of plant chiefly below the surface of the water 1. *W. COLUMBIANA*
- a. Plants with numerous minute brown dots, the upper surface not convex; shape of plant mainly ovate or oblong to ellipsoid; upper surface of plant floating chiefly above the surface of the water b
- b. Upper surface of plant nearly flat, raised at one end into a tiny papilla (bump) 2. *W. PUNCTATA*
- b. Upper surface of plant with a tiny pointed papilla (bump) near the center 3. *W. PAPULIFERA*

1. ***Wolffia columbiana*** Karst. Water-meal

Map 562

Occurs in still waters of ponds and sloughs. Scattered in parts of central and southwestern Missouri.

Ranges from South and Central America to Mexico, north to Massachusetts, Quebec, New York, Ontario, Michigan, Wisconsin, and Minnesota.

Plants of this species measure 0.3–1 mm. long and nearly as wide. They are recorded as being eaten by ducks and muskrats.

2. ***Wolffia punctata*** Griseb. Water-meal

Map 563

Known only from the cool waters of a spring-fed lake of Yancy Mills Spring in Phelps County of the

Ozark section.

Ranges from the West Indies, and from Florida and Texas, north to Connecticut, New York, Ontario, Michigan, and Minnesota.

Eaten by ducks and muskrat.

3. ***Wolffia papulifera*** Thompson

Water-meal

Map 564

Occurs in sloughs, and in stagnant waters of ponds and slow-flowing streams, often in organic floating debris of sink-hole ponds. Scattered in southern and central Missouri, frequent in sink-hole ponds of the southern Ozarks.

Ranges from Virginia to Illinois, Kentucky, Tennessee, Missouri, Arkansas, and Kansas.

4. ***Wolffiella*** Hegelm.

Wolffiella floridana (Smith) Thompson Map 565

Known only from the swamps of the southeastern lowland section of the state in Dunklin County (Kennett, April 24, 1897, *Trelease*; St. Francis River, August 6, 1895, *Widmann*).

Ranges from Mexico, Florida and Texas, north to

Massachusetts, Ontario, Michigan, Wisconsin, and Missouri.

Plants occur either singly or in star-shaped pale green bodies, often forming tangled masses, usually just the base of the plant showing above the surface of the water. They are eaten by wildfowl.

Plate no. 103. 1. *Lemna minor*; a. $\times \frac{3}{4}$; b. $\times 3$. 2. *Lemna minima*; a. $\times \frac{3}{4}$; b. $\times 3$. 3. *Lemna perpusilla*; a. $\times \frac{3}{4}$; b. $\times 3$. 4. *Lemna valdiviana*; a. $\times \frac{3}{4}$; b. $\times 4\frac{1}{2}$. 5. *Wolffia columbiana*; a. $\times \frac{3}{4}$; b. top view, $\times 15$; c. side view, $\times 15$. 6. *Wolffia punctata*; a. $\times \frac{3}{4}$; b. top view, $\times 15$; c. side view, $\times 15$. 7. *Wolffia papulifera*; a. $\times \frac{3}{4}$; b. top view, $\times 7\frac{1}{2}$; c. side view, $\times 18\frac{3}{4}$. 8. *Wolffiella floridana*; a. $\times \frac{3}{4}$; b. cluster of leaves in natural position in water, $\times 3\frac{3}{4}$; c. single leaf, $\times 3\frac{3}{4}$; d. cluster of leaves, top view, $\times 3\frac{3}{4}$.

Map 566

Xyris flexuosa [of P & S], not Muhl.

Flowers July–September.

Very rare and local in Missouri, where known only from two localities in the southwestern sector of the state, in Greene (Asher, July 16, 1887, *Blankinship* in Drury College herbarium; Goose Pond, *Bush*) and Lawrence (wet sandy soil in deep railway cut through Pennsylvanian sandstone, 2 mi. southeast of Aurora, July 13, 1953, *Palmer 56161* [in bud]; same locality, along ditches, August 25, 1953, *Palmer 56626* [in flower]) counties.

Ranges from Georgia to Arkansas and Texas,

north to New Hampshire, New York, Ohio, Minnesota, and Iowa.

The flowers are yellow and have 3 sepals, 3 petals with claws, 3 stamens, a 3-cleft style, and a 1-celled ovary with many ovules or seeds on parietal placentae. The flowers are arranged in the axils of the overlapping scales, the whole resembling a tiny pine cone, at the tip of a long green scape (leafless stem bearing the flowers). The grasslike leaves are erect and arise from the thickened bulbous base of the plant.

Mallard ducks are known to feed on the seeds of this and other species of the genus.

Fam. **COMMELINACEAE** (Spiderwort Family)

The 3 petals equal, all alike; stamens 6, all alike; flowers not surrounded by a folded spathe . . . 1. **TRADESCANTIA**
One of the petals slightly or much smaller than the other 2; 3 of the 5 or 6 stamens smaller and different;
flowers surrounded by a folded spathe 2. **COMMELINA**

1. **Tradescantia** L. Spiderwort

The following key will separate the majority of plants encountered. It should be pointed out, however, that the species hybridize or cross with one another, so that combinations of characters may be found on a few specimens which do not appear to fit those given in the key.

- a. Dwarf plants with short stems 2–10 cm. tall and crowded leaves b
- b. Sepals or pedicels or both bearing some gland-tipped hairs (tiny swellings or knobs at the tip)
(use magnifying lens of 10 ×) c
- c. Plants of prairies, meadows, railroads, and open roadsides of the northern 2/3 of the state 7. **T. BRACIATEATA**
- c. Plants of woodland in the southeastern or southwestern Ozark region d
- d. Leaf-blades 5–12 mm. wide, hairy, dull or grass-green without any glaucous covering (smooth gray or silvery coating which can be rubbed off); petals deep purple, deep blue or deep rose; southeastern Ozark region 8. **T. LONGIPES**
- d. Leaf-blades 15–50 mm. wide, hairless except for minutely hairy margins, more or less glaucous and silvery or gray-green; petals of light shades of pink or lavender-blue, or white; southwestern Ozark region 2. **T. OZARKANA**

- b. Sepals or pedicels with no gland-tipped hairs (use magnifying lens of 10 ×) e
- e. Blades of the upper leaves much broader than their sheaths 3. *T. ERNESTIANA*
- e. Blades of the upper leaves narrower than or about as broad as their sheaths f
 - f. Stems and leaves with many conspicuous hairs; leaves usually edged with pink or purple; sepals petal-like, thin with usually purplish tips or margins, not inflated; southwestern Missouri plants 5. *T. THARPII*
 - f. Stems and leaves mainly glabrous (without hairs) or with a few sparse hairs at most; leaves not edged with purple; sepals green, more or less inflated; plants of the eastern half of Missouri 4. *T. VIRGINIANA*
- a. Plants averaging 15–70 cm. tall g
- g. Sepals glabrous, or if hairs are present, they are at the very tip and do not bear glands at tip
 - 6. *T. OHIENSIS* (the hybrid between *T. OHIENSIS* and *T. SUBASPERA* may be keyed here)
- g. Sepals with numerous hairs from base to tip h
- h. Blades of at least the upper leaves much broader than their sheaths i
 - i. Plants of the eastern half of Missouri west to the central part of the state, west to Saline, Pettis, Camden, and Ozark counties; pedicels (flower-stalks) 10–17 mm. long; stem more or less conspicuously zigzag or flexuous; flowers pale to deep blue; flowering mostly from the first week of June through September 1. *T. SUBASPERA*
 - i. Plants of southwestern Missouri only, east to Douglas and Ozark counties; pedicels 20–32 mm. long; stem more or less straight; flowers white, pale pink, pale to deep purple, lavender-blue, rose-red, or deep blue; flowering mostly in April and May j
 - j. Sepals 4–10 mm. long, not inflated, with some gland-tipped hairs (with a minute swelling or knob at tip); leaf-blades more or less glaucous (with a whitish coating which can be rubbed off) and silvery or gray-green; petals of light shades of pink or lavender-blue or white 2. *T. OZARKANA*
 - j. Sepals 10–14 mm. long, more or less inflated, without any gland-tipped hairs; leaf-blades deep green, not glaucous; petals usually deep blue, pale to deep purple or rose-red 3. *T. ERNESTIANA*
- h. Blades of the upper leaves narrower than to about as broad as their sheaths k
- k. Sepals with gland-tipped hairs; plants of the prairies, meadows, railroads, and open roadsides 7. *T. BRACTEATA*
- k. Sepals without any gland-tipped hairs; plants of the woodland or ledges along bluffs or sandstone exposures 4. *T. VIRGINIANA*

1. ***Tradescantia subaspera* Ker. var. *subaspera***

Map 567

Tradescantia subaspera Ker. [G, P & S]

Flowers first week of June–September.

Occurs in rich woods, shaded bluffs, usually of limestone areas, and in wooded valleys along streams. Eastern and middle Missouri north to Lewis and Shelby counties, west to Saline, Pettis, Morgan, Camden, Texas, and Ozark counties; absent from the southeastern lowland section. Another variety, var. *montana* (Shuttlw.) Anderson & Woodson, occurs in some of the southeastern states.

Ranges from West Virginia to Illinois, south to Tennessee, and Missouri.

This hybridizes with no. 6 (*T. ohiensis*), producing a plant with the broader leaf-blades and somewhat zigzag stems of *T. subaspera*, the silvery glaucous character of the leaf of *T. ohiensis*, the mostly glabrous or hairy-tipped sepals of *T. ohiensis*, and the cymes of flowers terminal and from the upper nodes of the stem, a character of *T. subaspera*. The hybrid is known from Monroe, Boone, and Washington counties.

Tradescantia subaspera is a good plant for wildflower gardens, flowering throughout the summer and fall months in shaded areas. It favors a rich loamy soil.

2. ***Tradescantia ozarkana* Anderson & Woodson**

Map 568

Flowers April–May.

Occurs in rich rocky woods, steep wooded slopes, and moist ledges along wooded bluffs, in limestone areas. Occurs along the White River and tributaries of southwestern Missouri from Ozark County west to Barry County.

Ranges from southwest Missouri and northwestern Arkansas to eastern Oklahoma.

Tradescantia ozarkana varies in color of petals from white to pink, rose, or lavender. This species was formerly abundant along the White River and tributaries, but the impoundments of the various dams which have been erected have destroyed millions of plants.

This species hybridizes with no. 3 (*T. Ernestiana*) in Barry County at Eagle Rock near Roaring River State

568 *Tradescantia ozarkana* (Spiderwort)569 *Tradescantia Ernestiana* (Spiderwort)570 *Tradescantia virginiana* f. *virginiana* (Spiderwort)

Park, and with no. 6 (*T. ohimensis*) in Ozark (*Steysmark 27091*) and Taney (*Steysmark 5267* and *5268*) counties. The latter hybrid is a broad-leaved, glaucous plant with often glabrous or only hairy-tipped sepals.

The stems vary from glabrous (the usual condition) to very pubescent (*Steysmark 5293* from Taney County).

The plant does well in wildflower gardens when provided with rich, well-drained, shaded soils.

3. ***Tradescantia Ernestiana*** Anderson & Woodson
f. ***Ernestiana*** Map 569

Flowers April–May.

Occurs in valleys, ravines, rich or rocky slopes of woodland, and wooded ledges of bluffs, where it is found in southwestern Missouri east to Douglas and Ozark counties, north to Greene and Jasper counties; introduced around Syracuse in Morgan County (herbarium Wm. Jewell College).

Ranges from southwestern Missouri to northwestern Arkansas, and eastern Oklahoma.

As noted above, this species crosses in nature with no. 2 (*T. ozarkana*). The colors of the petals of *T. Ernestiana* run to deeper shades of blue, rose-red, and deep purple than those in *T. ozarkana*. A white-flowered form, f. *alba* Waterfall, has not yet been recorded from Missouri. The species does very well in wildflower gardens in rich, shaded soils.

4. ***Tradescantia virginiana*** L. f. ***virginiana***

Map 570

Tradescantia virginiana L. [BB, G, P & S]

Flowers late April–June.

Occurs in rocky or nonrocky open wooded slopes or valleys, often on the crests or upper slopes in acid soils overlying sandstone, chert, or granite, and along

moist shaded ledges of wooded bluffs of sandstone and granitic rocks. Found in the eastern half of Missouri west to Scotland, Shelby, Boone, Crawford, Reynolds, Carter, and Ripley counties, and locally southwest in Douglas County. The Jackson County record (barrens, Dodson, May 10, 1896, *Mackenzie* in the herbarium of New York Botanical Garden), cited in the work on *Tradescantia* by Anderson and Woodson (*Contr. Arn. Arb.* 9: 65, 1935), and the record from Clinton County cited in Palmer and Steysmark's *Annotated Catalogue* should be deleted for this species and transferred to *T. bracteata* instead.

Ranges from Connecticut to Wisconsin, south to Georgia, Tennessee, and Missouri; escaped northeast to Maine.

The usual color of this species is a deep purple, blue, or deep blue-purple or violet, occasionally a deep rose-red. A white-flowered form, f. *albiflora* Britt., has not yet been recorded from Missouri, but is to be expected. The leaves are either glabrous or have some scattered hairs on the surface and margins of the blades, and vary from narrow- to broad-leaved types.

Hybrids between this species and no. 6 (*T. ohimensis*) have been found in Mississippi (*Steysmark 10338*) and Butler counties, producing plants in habit somewhat intermediate with low stature only 3 dm. tall, subglaucous leaves with the upper ones recurved, and the sepals varying from glabrous to bearded at the tip to pubescent throughout.

Dwarf plants with more crowded leaves and short stems less than 1 dm. tall are sometimes puzzling and confused with *T. longipes* or *T. Tharpii*. The non-glandular hairs of the inflated green calyx and more glabrous stems and leaves distinguish this species from *T. longipes*, and the shorter pedicels, inflated green

PLATE NO. 104

571 *Tradescantia Tharpaii* (Spiderwort)572 *Tradescantia ohiensis* (Spiderwort)573 *Tradescantia bracteata* (Spiderwort)

sepals, and mainly glabrous stems and leaves distinguish it from *T. Tharpaii*.

Tradescantia virginiana favors acid soils similar to those of *T. longipes*. Cultivated plants have been derived from *T. virginiana* and hybrids between it and other species. The fleshy juicy leaves and stems of this and other species of *Tradescantia* are sometimes eaten as a salad or cooked green vegetable.

5. ***Tradescantia Tharpaii*** Anderson & Woodson
Map 571

Flowers April–May.

Occurs usually on rocky prairies of sandstone or chert, or on sandstone, limestone, or chert glades and open slopes, and along railroads in southwestern Missouri in the unglaciated prairie section north and east to Polk and Greene counties.

Ranges from southwestern Missouri and Kansas to Oklahoma and Texas.

The sepals, as in *T. longipes*, are somewhat thin and petal-like with a purple or rose hue, and not inflated and completely green, as in *T. virginiana* or *T. Ernestiana*. The color of the petals varies from deep rose to purple or purplish-blue.

This species hybridizes with no. 6 (*T. ohiensis*) in Lawrence (Steyermark 22224; Palmer 53722) and Jasper (Palmer 30130, 48587-A) counties.

6. ***Tradescantia ohiensis*** Raf.
Tradescantia canaliculata Raf. [P & S]
Map 572

Flowers early May–July.

Commonly occurs in prairies, meadows, thickets, and along railroads and roadsides, more rarely in open woodland. Found throughout Missouri; not recorded from a couple of counties in extreme northwestern Missouri, and three counties in the extreme southeastern section.

Ranges from Massachusetts to Minnesota and Nebraska, south to Florida and Texas.

The color of the petals is normally a clear blue,

but rose and purplish-lavender colors occasionally occur. White-flowered forms are rarely noted. The petals vary in size, in some individuals being much larger than normal.

This species has been recorded as hybridizing with all the other species in Missouri except *T. Ernestiana* and *T. bracteata*, and eventually hybrids will probably be found with these latter two as well.

The leaf-sheaths vary from glabrous to hairy, and the sepals from completely glabrous to tipped with nonglandular hairs.

This species is glaucous with a silvery-green color on all parts and easily recognized by this character together with the glabrous stems, leaves, and sepals.

7. ***Tradescantia bracteata*** Small
Map 573
Flowers May–July.

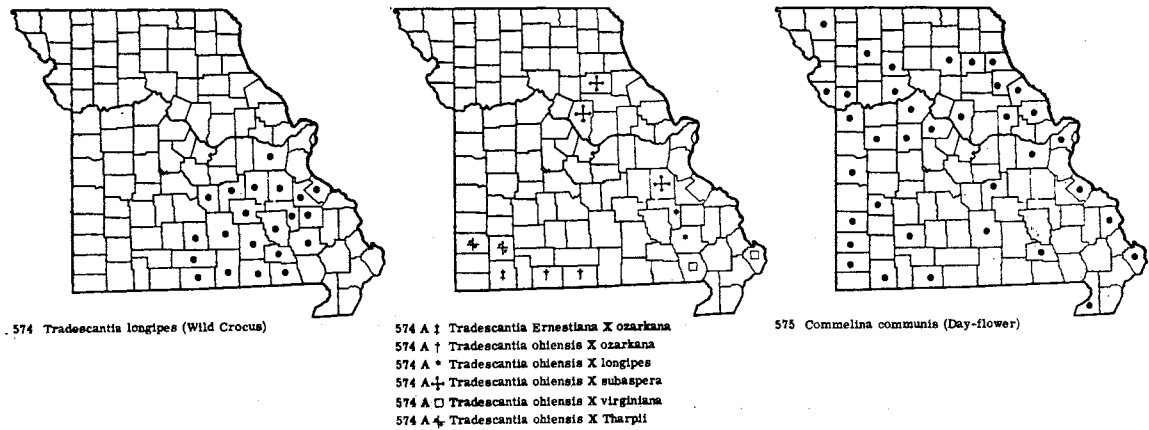

Occurs usually in open exposed soils of prairies, meadows, along railroads and roadsides in northern and central Missouri south to Jefferson, Cooper, Henry, and Vernon counties, and locally south in Phelps County.

Ranges from Michigan to Montana, south to Indiana, Illinois, Missouri, and Kansas.

The color range of this species is quite varied, ranging from usually bright rose to purple, less frequently blue, lavender, violet, white, and blends of combinations of these colors. Plants of this species do well in garden beds exposed to full sun, and increase rapidly from the roots. Unlike most of the other species of Missouri, which retain their foliage for a relatively long period after flowering, this species quickly disappears after the short blooming season. The leaves vary from narrow- to broad-leaved types.

8. ***Tradescantia longipes*** Anderson & Woodson
Wild Crocus
Map 574
Flowers April–May.

Occurs on slopes or level valleys of rocky open woodland in acid soils associated with sandstone, chert,

granite or porphyritic rock. Restricted to the Ozark section of the state, extending north to Franklin, Phelps, and Pulaski counties, west to Wright, Douglas, and Ozark counties. It occurs commonly on dry upland slopes and crests of hills and ridges where chert or Roubidoux sandstone predominates, and is frequently found in pine-oak woodland. Not known outside of Missouri, but to be expected in northern Arkansas.

Sometimes known as wild crocus in the St. Francois hills section of the Ozarks (St. Francois, Madison, Iron, and Reynolds counties), the flowers of this species appear to arise just above the ground level and are usually deep purple, violet, or deep rose, occasion-

ally pink or bluish. It is a desirable type of plant for the rock-garden, but requires an acid soil free of lime rock. The flowers have a pleasant fragrance, resembling that of lily-of-the-valley.

Tradescantia longipes hybridizes with *T. ohniensis*, records having been collected from Iron and Wayne counties, producing a plant with longer stems, and longer, somewhat glaucous leaves, combined with thin somewhat rose-colored sepals.

The pedicels are longer than those of *T. Tharpit*, the other dwarf species which it resembles, and the stem does not elongate as much in fruit as in *T. Tharpit*.

2. **Commelina** L. Day-flower

- a. The folded green spathe that surrounds the flowers is open from one end to the flower, the margins being free all the way to the base; plants with slender roots b
- b. The smallest 1 of the 3 petals white; the larger 2 blue petals with the main part (blade) 8–15 mm. long, ovate; anthers 6; leaf-sheaths rarely with long hairs along the margins at the summit; flower stalks (peduncles) 10–50 mm. long, not hair-like 1. *C. COMMUNIS*
- b. All 3 petals blue; the larger 2 blue petals with the main part (blade) 2.5–8 mm. long, bean-shaped; anthers 5; leaf-sheaths with long hairs along the margins at the summit; flower stalks (peduncles) 5–20 mm. long, hair-like c
- c. The green spathe 25–35 mm. long; stems erect or spreading 2. *C. CAROLINIANA*
- c. The green spathe 10–25 mm. long; stems creeping 3. *C. DIFFUSA*
- a. The folded green spathe has its margins united at the base (the end nearest the flower stalk); plants with thick roots d
- d. Leaf-sheaths not prolonged at the top, with rusty-colored bristles on the margins; all 3 petals blue, nearly equal; plants of low moist woodland 4. *C. VIRGINICA*
- d. Leaf-sheaths prolonged at the top into a spreading rounded loose piece with pale white hairs on the margins; 2 of the petals blue, 1 white and much smaller; plants of gravel and sand bars, stream banks, rocky hills and bluffs, and rocky woods 5. *C. ERECTA*

1. **Commelina communis** L. Day-flower
Map 575
Flowers May–October.
Occurs in cultivated and waste ground, moist allu-

vial soils, and in low woods and thickets. Throughout Missouri.
Native of Asia; introduced into the United States, ranging from Massachusetts to Wisconsin,

576 *Commelina caroliniana* (Day-flower)577 *Commelina diffusa* (Day-flower)578 *Commelina virginica* (Day-flower)

outh to Alabama, Arkansas, Kansas, and Nebraska.

Two varieties, var. *communis* and var. *ludens* (Miq.) Clarke, have been distinguished as follows:

var. *communis*. Main part (blade) of larger petals 10–15 mm. long, pale violet-blue; lobed sterile anthers all yellow; leaf-sheaths glabrous at the summit and on the margins.

var. *ludens*. Main part (blade) of larger petals 8–10 mm. long, deep violet-blue; lobed sterile anthers with a madder-brown center; leaf-sheaths usually with short hairs on the summit and margins.

Apparently both varieties occur in the state, but their proper status remains to be more carefully evaluated.

This is the common day-flower often encountered around dwelling places, alleys, back yards, and as a weed in gardens. In the East Indies the plants are reported to be cooked and eaten as a green vegetable.

2. *Commelina caroliniana* Walt. Day-flower

Map 576

Flowers August–September.

Introduced in Jackson County, west-central Missouri (Sheffield, August 30, 1905, *Bush* 3307; Sheffield, September 14, 1905, *Bush* 3332).

Ranges from South Carolina to Florida west to Mississippi; introduced in Missouri.

The specimens collected by Bush were originally identified by him as *C. nudiflora*. The spathes on the specimens are elongate, acuminate, and their margins are free to the base. They are clearly not *C. elegans* HBK., a species having closed spathes with a short apex, but were filed under that species at the Gray Herbarium.

3. *Commelina diffusa* Burm. Day-flower

Map 577

Commelina longicaulis Jacq. [P & S]

Flowers early July–October.

Occurs in moist sandy or muddy alluvial soils of river bottom, in low fields, valleys, and moist open cultivated ground, sometimes weedy. Common in all of southern and central Missouri north to Shelby, Macon, Saline, and Jackson counties.

Ranges from South and Central America, the West Indies, and Mexico, north in the United States to Virginia, Ohio, Indiana, Illinois, Missouri, and Kansas; introduced in Massachusetts; also in the Old World tropics.

The slender stems creep along the moist ground, rooting at the joints (nodes). The black seeds are 2–3 mm. long.

This species, likewise, is reported to be cooked and eaten as a green vegetable.

4. *Commelina virginica* L. Day-flower Map 578

Flowers July–September.

Occurs in wet low woodland in valleys along streams, and borders of swamps and sloughs. Found throughout the Ozark and southeastern lowland section, extending north to St. Louis, Franklin, Osage, Cole, Camden, St. Clair, and Barton counties, and locally northwest in Jackson County.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Kentucky, Illinois, Missouri, and Kansas.

This species is the most robust of the native species of *Commelina* with stout erect stems up to 1.2 meters tall, and spiderwort- or lilylike dark green leaf-blades 2.5–5 cm. broad and up to 20 cm. long. The spathes

Plate no. 105. 1. *Tradescantia Tharpia*, $\times \frac{2}{7}$. 2. *Commelina erecta* var. *erecta*, $\times \frac{2}{7}$. 3. *Tradescantia ohiensis*, $\times \frac{2}{7}$. 4. *Tradescantia bracteata*, $\times \frac{2}{7}$. 5. *Tradescantia longipes*, $\times \frac{2}{7}$. 6. *Commelina diffusa*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{1^3}{7}$; b. X-section of fruit; c. Seed, highly magnified; After Britton and Brown, details from Small, The New York Botanical Garden. 7. *Commelina virginica*; a. Fruit, $\times \frac{1^3}{7}$; After Britton and Brown, The New York Botanical Garden.

 581 ● *Pontederia cordata* f. *latifolia*

are crowded near the summit of the stem and surround the large blue flowers, the blades of which are 10 mm. or more long. It is a handsome species.

5. ***Commelina erecta* L.** Day-flower Map 579
 Flowers last of May–October.

Occurs commonly on sand and gravel bars, alluvial banks of streams, rocky wooded slopes, and exposed bluffs and glades. Common throughout the Ozark region in southern and central Missouri, locally north in northern Missouri.

The following varieties are represented in Missouri material:

- a. The larger developed main leaves principally 20–40 mm. (sometimes 15) wide, lanceolate to ovate-lanceolate; mature spathes 22–36 mm. long b
- b. Spathes nearly glabrous or with short hairs
 - 5a. *C. ERECTA* var. *ERECTA* f. *ERECTA*
- b. Spathes with rather conspicuous white hairs
 - 5b. *C. ERECTA* var. *ERECTA* f. *INTERCURSA*
- a. The larger developed main leaves principally 4–20 mm. wide, linear to narrowly lanceolate; mature spathes 10–30 mm. long c
- c. Mature spathes mostly 10–20 mm. (sometimes up to 25) long; the longest leaves 4–10 cm. long d
- d. Spathes covered with short dense hairs
 - 5c. *C. ERECTA* var. *ANGUSTIFOLIA* f. *ANGUSTIFOLIA*
- d. Spathes with long white hairs at and near the base 5d. *C. ERECTA* var. *ANGUSTIFOLIA* f. *CRISPA*
- c. Mature spathes mostly 25–30 mm. long; the longest leaves 7–15 cm. long 5e. *C. ERECTA* var. *DEAMIANA*

The above arrangement, modified slightly from Fernald's original treatment (Rh. 42: 435–41. 1940),

will account for the variations to be encountered. Although some of the extremes of variation seem distinct enough, considerable overlapping between characters occurs. This intergradation and lack of correlation often break down the lines of separation between the various varieties and forms, casting considerable doubt as to their acceptability.

5a. ***Commelina erecta* var. *erecta* f. *erecta***

Map 579

Commelina erecta L. [G, P & S]

Scattered in southern and central Missouri.

Ranges from New York to Kansas, south to Florida and Texas.

This form and f. *intercursa* appear to be less common in Missouri than var. *angustifolia* f. *angustifolia* and f. *crispa*.

5b. ***Commelina erecta* var. *erecta* f. *intercursa***

Fern.

Map 579

Commelina erecta f. *intercursa* Fern. [G]

Scattered in southern and central Missouri.

Scattered within the range of f. *erecta*.

5c. ***Commelina erecta* var. *angustifolia*** (Michx.)

Fern. f. *angustifolia*

Map 579

Commelina erecta var. *angustifolia* (Michx.) Fern.

[G, P & S]

This is the commonest of the variations of *C. erecta* in Missouri, according to the known records. It and f. *crispa* are more commonly found on exposed places of glades, bluffs, and sand and gravel bars.

Ranges from Central America and Mexico, north into the United States to Delaware, West Virginia, Illinois, Missouri, and Nebraska.

A form with all white petals (f. *albina* Fern.) occurs, but has not yet been found in Missouri.

5d. **Commelina erecta** var. **angustifolia** f. **crispa** (Wooton) Fern. Map 579
Commelina erecta var. *crispa* (Wooton) Palmer & Steyer. [P & S]
Less common than var. *angustifolia* f. *angustifolia* in the state.
Found throughout the range of f. *angustifolia*.
The fleshy roots of *C. erecta* var. *angustifolia* f. *angustifolia* and f. *crispa*, and other varieties and forms of *C. erecta* contain considerable starchy carbohydrates

and have been suggested as being edible as a type of cooked vegetable.

5e. **Commelina erecta** var. **Deamiana** Fern. Map 579
This variety has been collected in Missouri thus far only in Dent, Taney, and Barry counties.
Ranges from Michigan and Indiana to Kansas and Texas.

Fam. **PONTEDERIAACEAE** (Pickerel-weed Family)

- a. Plants normally floating on the surface of water, the roots hanging below the surface; some or all the petioles of the leaves inflated, swollen around the middle and tenpin-shaped 1. **EICHHORNIA**
- a. Plants normally and usually rooted to mud, sand, or gravel in or out of water; petioles of leaves not inflated or tenpin-shaped b
- b. Plants 50-100 cm. tall; leaf-blades 5-15 cm. wide, mostly 10-20 cm. long; flowers numerous in a long dense spike; stamens 6; flowers irregular, 2-lipped 2. **PONTEDERIA**
- b. Plants 6-25 cm. tall, or, if taller, the leaves are grass-like; leaf-blades 0.2-6 cm. wide, mostly 2-6 cm. long, but if longer, then the leaves are grass-like; flowers 1-16, loosely-flowered; stamens 3; flowers regular, about equally 6-parted 3. **HETERANTHERA**

1. **Eichhornia** Kunth Water Hyacinth

Eichhornia crassipes (Mart.) Solms
Water Hyacinth Map 580
Flowers July-August.
Known only from drainage canals of the southeastern lowland section from Dunklin and Butler (Neeleyville, July 12, 1930, Kellogg 15142) counties.
Ranges from South and Central America, the West Indies, Mexico, north in the United States from Florida and Texas to Virginia and Missouri. Introduced in Europe and Asia.
The plant itself is not considered to have any direct

food value for wildfowl, but indirectly attracts minute animal life which in turn is eaten by fish and waterfowl.
In Florida and other sections of the United States, and in Europe, it has clogged up waterways and interfered seriously with navigation and water transportation to the extent of having become a serious pest. The young leaf-blades, petioles, and inflorescences are cooked and eaten by the inhabitants of the Dutch East Indies, where it was introduced.

2. **Pontederia** L. Pickerel-weed

Pontederia cordata L. Pickerel-weed Map 581
Flowers first week of June-October.
Occurs in sloughs, open swamps and oxbow ponds of river bottoms, and other ponds. Scattered in eastern and western sections of the state, and locally northward in Grundy County.
Ranges from Nova Scotia to Ontario and Minnesota, south to Florida, Missouri, and Oklahoma.
Missouri material is represented by the following 2 categories:
Leaves narrowly triangular-ovate, tapering with straight sides from the base to the apex.

Leaves broadly ovate, gradually curved from the broad base to the blunt summit . . . b. **P. CORDATA** f. **LATIFOLIA**

a. **Pontederia cordata** f. **cordata** Map 581
This is the less frequently encountered form in Missouri.

b. **Pontederia cordata** f. **latifolia** (Farw.) House Map 581
This is the common form in Missouri. The most northern station in the state for the form is in Livingston County (Gooseneck Lake, in bottoms of Thomp-

a. **P. CORDATA** f. **CORDATA**

582 *Heteranthera reniformis* (Mud Plantain)583 *Heteranthera limosa* (Mud Plantain)584 *Heteranthera dubia* (Water Star-grass)

son River, T60N, R24W, northwest sect. 34, 6½ mi. south of Trenton, August 10, 1952, *Steyermark* 74216). This is a natural lake which has many other interesting aquatic plants, such as *Myriophyllum heterophyllum*, *Utricularia vulgaris*, *Sparganium angrocladum*, *S. eurycarpum*, and *Anacharis Nuttallii*, some of which are not known elsewhere in northern Missouri.

Narrowly triangular-leaved (f. *angustifolia*) and submerged, linear-leaved (f. *taenia*) forms also have been described, but have thus far not been recorded from the state.

Gleason has identified the Missouri material as *P. lanceolata* Nutt., a tropical American species which extends north into the United States to Virginia and

Texas. Based upon the presence of a persistently pubescent perianth with short glandular hairs, all the Missouri material examined would key to *P. lanceolata*, according to Gleason's concept. However, the Missouri material appears not to differ in respect to the pubescence of the perianth from the widely distributed *P. cordata* to which species it is assigned in the present flora.

The ripe raw fruits are edible. It has been recommended that the fleshy stems and young leaves, raw or cooked, may be tried as a vegetable, since it is closely related to the edible southeastern Asiatic *Monochoria*. The seeds are eaten by ducks and muskrats.

3. *Heteranthera* R. & P. Mud Plantain

- a. Leaves grass-like, linear; flowers yellow, solitary 3. *H. DUBIA*
- a. Leaves broad, of an oval, oblong, round, or round-bean shape; flowers blue or white, 1-16 in the inflorescence b
- b. Leaf-blades longer than broad, narrowed to an acute, obtuse, or slightly heart-shaped base; flower only 1 in each inflorescence; tube of flower 20-35 mm. long 2. *H. LIMOSA*
- b. Leaf-blades about as broad as long with a deeply heart-shaped base; flowers 2-16 in the inflorescence; tube of flower 6-10 mm. long 1. *H. RENIFORMIS*

1. *Heteranthera reniformis* R. & P.

Mud Plantain

Map 582

Heteranthera peduncularis Benth. [BB]

Flowers July-October.

Occurs along sloughs, ditches of valleys and swampy depressions, and margins of artificial and natural ponds, especially of oxbow lakes in river bottoms. In southern and central Missouri, northwest along the Missouri River to Holt County.

Ranges from South and Central America, the West

Indies and Mexico, and in the United States from Florida to Texas, north to Connecticut, New York, Kentucky, Indiana, Illinois, Missouri, and Nebraska.

Sometimes plants may become detached from the muddy soil and float to the surface. Most of them remain rooted, however. The rich green leaves are very shiny.

Gleason (*New Illustrated Flora*, vol. 1: 385. 1952) has assigned specimens from western Missouri (ponds, Floyd, Jackson Co., July 11, 1921, *Bush* 9418A) to

Plate no. 106. 1. *Commelina communis*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden. 2. *Heteranthera dubia*, $\times \frac{2}{5}$; After Gleason, details from Small, The New York Botanical Garden. 3. *Pontederia cordata*, $\times \frac{2}{5}$; a. Flower, $\times \frac{2}{5}$; After Gleason, details from Small, The New York Botanical Garden. 4. *Eichhornia crassipes*, $\times \frac{3}{10}$; After Gleason, details from Small, The New York Botanical Garden. 5. *Heteranthera limosa*, $\times \frac{2}{5}$; After Gleason, The New York Botanical Garden. 6. *Heteranthera reniformis*, $\times \frac{2}{5}$; After Gleason, details from Small, The New York Botanical Garden.

PLATE NO. 106

H. peduncularis Benth., which is differentiated from *H. reniformis* as follows:

Spathe and the leaf next below it separated by a conspicuous internode; base of the short spike included by the spathe. *H. RENIFORMIS*

Spathe and the leaf next below it contiguous; base of the spike exerted from the spathe . . .

H. PEDUNCULARIS

I have not been able to separate the Missouri material on the above stated differences, and have assigned all the specimens to *H. reniformis*. Actually, the amount of exertion of the base of the spike from the spathe and development of a conspicuous internode below the spathe and the leaf next below it appear to be growth phases of the plant, rather than real criteria for the separation of species.

2. ***Heteranthera limosa*** (Sw.) Willd.

Mud Plantain

Map 583

Flowers June–September.

Occurs along sloughs, ditches, in artificial or natural ponds, and margins of slow streams. Southern and central Missouri north to Ralls, Cooper, Ray, and Buchanan counties.

Ranges from South and Central America, the West Indies, and Mexico, and in the United States from Florida to New Mexico, north to Kentucky, Illinois, Minnesota, Nebraska, and Colorado.

Plants are sometimes submerged with only the flowers protruding above the water surface.

3. ***Heteranthera dubia*** (Jacq.) MacM.

Water Star-grass

Map 584

Zosterella dubia (Jacq.) Small [BB]

Flowers June–September.

Occurs in streams, springs and spring branches,

and sloughs. Common throughout most of the streams in the Ozarks, where it extends north to St. Louis, Franklin, Gasconade, and Osage counties, westward to Camden, Dallas, Greene, and Stone counties, and locally outside the Ozarks in Boone, Jackson, and Holt counties.

Ranges from Florida to Texas and Mexico, north to Maine, New Hampshire, Quebec, Ontario, Minnesota, Idaho, and Washington.

This is a common species found in most of the Ozark streams, where it roots in the muddy gravel or sand beds near the shallower margins and banks; it favors mud substrata and is most frequently found on mud. It grows in both shallow or deep, and swift or still waters, often forming long leafy strands. The leaves may attain a length of 15 cm. Unlike some aquatic plants, it has a wide temperature tolerance, since it is found in the cold waters (54–60° F.) of Ozark spring branches and in the warmer waters of Ozark streams. Where the water is shallower or swifter, the plants may produce much shorter stems with shorter internodes, forming denser and more circular patches. Plants which get stranded on the mud outside of the water develop short and somewhat stiffish leaves and stems and have been named *H. dubia* f. *terrestris* (Farw.) Vict. As this is undoubtedly a mere ecological or temporary condition correlated with fluctuating water levels, it would not appear to merit formal recognition.

Wildfowl sometimes eat this species. The leaves have an olive green or dull green color. When the plants are found without flowers, they may be distinguished from similar looking species of *Potamogeton* by the complete absence of a midnerve in the leaves of *Heteranthera*.

Order LILIALES

Fam. JUNCACEAE (Rush Family)

Plants resembling grasses or sedges, but with small regular greenish or brownish flowers with 3 narrow sepals, 3 similar petals, 6 or 3 stamens, a superior ovary with 1 cell or 3 cells, and numerous ovules and seeds. No ligule, as occurs in the grasses, is found at the junction of the leaf-blade and leaf-sheath. However, an auricle (ear-like extension or membrane) may be present at the summit of the leaf-sheath, and is often an important character in distinguishing some of the species.

The pollen in this family is not known to cause hay fever, as it is in some of the grasses.

Plants without any hairs; ovules or seeds usually many 1. JUNCUS

Plants with hairs; ovules or seeds 3 2. LUZULA

1. **Juncus** L. Rush

The stems (culms) are either hollow or are solid with pith. It is necessary that plants be collected with mature fruits and with the complete underground parts present in order to reach a satisfactory identification.

- a. Inflorescence (flower-clusters) appearing to come from the side of the stem which continues upward as the involucre bract *b*
- b. Common throughout southern and central Missouri; culms (stems) close together in dense clumps, marked with vertical lines or ribs (seen best when dry); stamens 3 1. *J. EFFUSUS*
- b. Known only from west-central Missouri in Jackson and Lafayette counties; culms well separated, arising in a single row from a creeping rootstock, with a smooth unfurrowed surface, or the surface not vertically lined or ribbed; stamens 6 2. *J. BALTICUS* var. *LITTORALIS*
- a. Inflorescence (flower-clusters) at the very tip of the stem *c*
- c. Leaves without any cross partitions which show up as darker or harder places at regular intervals *d*
- d. Flowers crowded together in 2-12-flowered heads with only a bract at the base of each pedicel and no pair of bracteoles at the base of the flower; leaves 1-7 mm. wide *e*
- e. Culms (stems) stout, 3-5 mm. thick at base, 6-13 dm. tall; leaves at the base mainly 4-7 mm. wide; heads mainly 20-100 to a stem; stamens exerted (protruding above the sepals and petals) in fruit or equaling the sepals, persistent 10. *J. BIFLORUS*
- e. Culms (stems) slender, mainly 1-2 mm. (up to 3) thick at base, 1.5-6 dm. (up to 8) tall; leaves at the base mainly 1-5 mm. wide; heads mainly 2-20 (up to 30) to a stem; stamens not exerted in fruit, shorter than sepals, not persisting but shriveling 9. *J. MARGINATUS*
- d. Flowers occurring either singly or scattered on the branches of the inflorescence, or, if more or less clustered, each flower has 2 bracteoles at its base and 1 bractlet at the base of the pedicel; leaves 0.5-1.5 mm. wide *f*
- f. Inflorescence taking up $1/3$ - $3/4$ or more the height of the entire plant; plants annual with a soft base; leaf-sheaths without any auricles 3. *J. BUFONIUS*
- f. Inflorescence mainly $1/5$ or less the height of the entire plant (rarely $1/4$ the height); plants perennials with a firm hard base; leaf-sheaths with auricles (ear-like extensions or loose membranes) at summit *g*
- g. Auricles at summit of leaf-sheath white and very thin, 1-3.5 mm. long, loose, like a tiny flap protruding at the summit of the sheath 6. *J. TENUIS*
- g. Auricles at summit of leaf-sheath short and rounded, not loose or protruding as a tiny flap *h*
- h. Involucre bract (leaf at base of inflorescence) shorter than the inflorescence; auricle thin and membranous; flowers chiefly arranged along the inner side of the branches which curve in near the tips; leaves usually less than $1/3$ the height of the culms (stems); perianth 2.5-3.5 mm. long 5. *J. SECUNDUS*
- h. Involucre bract longer than the inflorescence; auricle either firm or rigid like cartilage; flowers somewhat clustered, crowded, or, if loosely branched and scattered, not arranged just along the inner side of the branches; leaves usually about $1/2$ the height of the culms (stems); perianth mainly 3.6-6 mm. (sometimes 3) long *i*
- i. Auricles yellow and glossy, rigid, like cartilage 8. *J. DUDLEYI*
- i. Auricles pale brown or gray-brown, greenish or straw-colored, firm but not rigid or glossy *j*
- j. The 2 small bracteoles at the base of each flower sharp-pointed or tapering to a conspicuous point; capsule 1-celled or imperfectly 3-celled; sepals and petals erect and appressed to capsule or slightly spreading, 3-4 mm. long 7. *J. INTERIOR*
- j. The 2 small bracteoles at the base of each flower blunt or slightly pointed at tip; capsule completely 3-celled; sepals and petals spreading-ascending, mostly 4-6 mm. long 4. *J. KANSANUS*
- c. Leaves with cross partitions which show up as darker or harder places at regular intervals *k*
- k. Sepals and petals more or less obtuse or blunt at tip; known only from Jackson County, west-central Missouri 22. *J. ALPINUS* var. *FUSCESCENS*
- k. Sepals and petals tapering to a narrow or slender-pointed tip *l*
- l. Fruiting capsule twice or nearly twice as long as the sepals and petals; fruiting capsule lanceolate-linear; flowers only 2-7 in each head 21. *J. DIFFUSISSIMUS*
- l. Without the above combination of characters; fruiting capsule either shorter or somewhat longer than the sepals and petals, but never nearly twice as long *m*
- m. Capsule conspicuously shorter than the sepals and petals, only $1/2$ - $2/3$ their length 15. *J. BRACHYCARPUS*
- m. Capsule equaling or longer than the sepals and petals, or at least only slightly shorter than the sepals and petals *n*
- n. Seeds with tail-like tips or appendages at each end (examine with magnifying lens $10\times$ or binocular microscope) *o*

588 *Juncus kansasus*589 *Juncus secundus*590 • *Juncus tenuis* f. *tenuis* (Path Rush)
590 □ *Juncus tenuis* f. *anthelatus*
590 x *Juncus tenuis* f. *discretiflorus*

This species serves occasionally as the food of muskrat. In Guatemala, the stems are used for weaving mats.

2. ***Juncus balticus* Willd. var. *littoralis* Engelm.** Map 586

Flowers May–September.

Occurs in prairie swales along railroads and in sand bars and mud flats along the Missouri River. Known only from west-central Missouri in Jackson and Johnson (wet low place in prairie along highway 58 and railroad, T46N, R28W, northeast $\frac{1}{4}$ sect. 5, 3 mi. northwest of Holden, May 18, 1949, *Steyermark* 67897).

Ranges from Labrador to British Columbia, south to New York, Pennsylvania, Ohio, Indiana, Illinois, Missouri, and Kansas.

3. ***Juncus bufonius* L. var. *bufonius*** Map 587
Toad Rush
Juncus bufonius L. [G, P & S]
Flowers late May–November.

Occurs in sandy and gravelly ground along the Missouri River and in waste places on moist shady paths in open upland woods of Crowley Ridge. Found along the Missouri River in Clay and Jackson counties in west-central Missouri and on Crowley Ridge in Dunklin County (May 26, 1939, *Steyermark* 26592).

Ranges throughout North America; also in the Old World.

4. ***Juncus kansasus* Herm.** Map 588
Flowers June–August.

Occurs on dry rocky slopes in Pike County, east-central Missouri (Eolia, June 25, 1917, *Davis* 8824) and on upland sandstone glades and sandy prairies

of the unglaciated prairie section of southwestern Missouri in Henry, St. Clair, and Dade counties.

Known only from Missouri and Kansas.

5. ***Juncus secundus* Beauv.** Map 589
Flowers late May–October.

Occurs on dry upland prairies, sandy or rocky open ground, and along railroads, in acid soils. Southern and central Missouri north to Lincoln, Moniteau, and Pettis counties, and west to St. Clair, Dade, and Barry counties.

Ranges from Maine to Ontario and Indiana, south to Georgia, Tennessee, Missouri, and Arkansas.

6. ***Juncus tenuis* Willd. Path Rush** Map 590
Flowers late May–September.

Missouri material is represented by the following varieties and forms, the key adapted from the work of Dr. Hermann:

- a. Flowers clustered 2–6 together at the tips of the branches. 6a. *J. TENUIS* f. *TENUIS*
- a. Flowers scattered along the axis of the branch. b
- b. Ultimate flowering branches rarely over 4 cm. long; sepals about same length as petals; capsule averaging $\frac{3}{4}$ length of the sepals 6b. *J. TENUIS* f. *ANTHELATUS*
- b. Ultimate flowering branches up to 7 cm. long; sepals usually longer than the petals; capsule averaging $\frac{1}{2}$ length of the sepals 6c. *J. TENUIS* f. *DISCRETIFLORUS*

6a. ***Juncus tenuis* f. *tenuis*** Map 590
Juncus tenuis Willd. [G]
Juncus macer S. F. Gray [P & S]

Occurs commonly in paths and along roadsides, open woods, fields, pastures, wet open ground, along streams, and waste places. Throughout Missouri, and doubtless in every county.

PLATE NO. 108

591 *Juncus interior*592 *Juncus Dudleyi*593 • *Juncus marginatus* var. *marginatus*
593 □ *Juncus marginatus* var. *setosus*

Ranges throughout North America, Mexico, Central and South America, and in Europe, North Africa, and Australia.

The seeds and stems are eaten by various wildfowl. Deer also browse the plants. Other species of *Juncus* are known to furnish seed for various song and marsh birds and wildfowl.

6b. *Juncus tenuis* f. *anthelatus* (Wieg.)

Herm.

Map 590

Juncus tenuis var. *anthelatus* Wieg. [G]

Juncus macer var. *anthelatus* (Wieg.) Fern. [P & S]

Scattered throughout the range of f. *tenuis* and somewhat less common. As in Indiana, this form is usually found in wetter places bordering ponds and low fields, and less frequently on paths or dry roadsides.

6c. *Juncus tenuis* f. *discretiflorus* (Herm.)

Fern.

Map 590

Juncus macer f. *discretiflorus* Herm.

This is the least common of the forms of *J. tenuis* in Missouri. It is known thus far from Lewis, Howell, Laclede (swampy meadow and pond in depression along road, T33-34N, R16-17W, sect. 36, 8 mi. southwest of Lebanon, July 5, 1947, *Steyermark 64701*), and Barton counties.

Known from Guatemala and a few states in the United States (Ohio, Indiana, Kentucky, Illinois, and Missouri, and elsewhere).

7. *Juncus interior* Wieg.

Map 591

Flowers May–August.

Occurs in upland prairies, prairie swales, meadows, limestone, sandstone, or chert glades, fallow fields, and openings. Throughout Missouri, except not recorded from the southeastern lowland section.

Ranges from Ontario, Michigan, and Wisconsin to Wyoming, south to Indiana, Illinois, Missouri, Arkansas, Kansas, Texas, and New Mexico.

8. *Juncus Dudleyi* Wieg.

Map 592

Flowers May–September.

Occurs along calcareous spring branches, borders of streams and ponds, swampy calcareous and other meadows, wet places in prairies, and moist ground. Restricted, except for a station in Jackson County, to the Ozark region, extending there to Franklin, Maries, Morgan, and Pettis counties.

Ranges from Newfoundland to British Columbia, south to Maryland, Tennessee, Missouri, Oklahoma, Texas, New Mexico, Arizona, and Mexico.

The inflorescence is somewhat compact, the flowers chiefly in small clusters, and the sepals and petals usually spreading-ascending and mainly 4–6 mm. long. This species is characteristic of calcareous spring branches and wet meadows of small valleys in the Ozark region.

9. *Juncus marginatus* Rostk.

Map 593

Flowers May–September.

Missouri material may be divided into two categories:

Petals blunt or somewhat rounded at tip with a short abrupt point, ovate to oblong

9a. *J. MARGINATUS* var. *MARGINATUS*

Petals with a long and slender tip, lanceolate .

9b. *J. MARGINATUS* var. *SETOSUS*

9a. *Juncus marginatus* var. *marginatus*

Map 593

Occurs in prairies, meadows, sandstone glades and open sandy ground, limestone glades, and sterile upland fields. Throughout the Ozark region in southern

594 ● *Juncus biflorus* f. *biflorus*
594 □ *Juncus biflorus* f. *adinus*

595 *Juncus canadensis* var. *canadensis*

596 *Juncus subcaudatus* var. *subcaudatus*

and central Missouri, north along the eastern border of the state to Clark County.

Ranges from Florida to Texas, north to Nova Scotia, Maine, New York, Ontario, Michigan, Missouri, and Kansas.

This is the commoner of the two varieties in the state.

9b. *Juncus marginatus* var. *setosus* Coville

Map 593

Occurs in similar situations as var. *marginatus*. Known from several counties in the southern third of the state.

Ranges from Central America and Mexico, and in the United States from Florida to Texas, north to Wisconsin, Minnesota, and Nebraska.

10. *Juncus biflorus* Ell.

Map 594

Flowers May–September.

Occurs in wet meadows, prairie swales, and sandy open ground, usually in acid soils.

Ranges from Florida to Texas, north to Massachusetts, Pennsylvania, Ohio, Michigan, Illinois, Missouri, and Oklahoma.

Missouri material is represented by the following categories:

Flower-clusters mainly 2–3-flowered (up to 6), scattered or well separated in a more or less loose inflorescence . . . 10a. *J. BIFLORUS* f. *BIFLORUS*

Flower-clusters mainly 3–6-flowered, close together or crowded in a compact inflorescence .

10b. *J. BIFLORUS* f. *ADINUS*

10a. *Juncus biflorus* f. *biflorus*

Map 594

Found in southern and central Missouri, where restricted to the Ozark and the unglaciated prairie sections.

This is the form more commonly encountered in the state.

10b. *Juncus biflorus* f. *adinus* Fern. & Griseb.

Map 594

Scattered in portions of the range of *biflorus*.

Both *J. biflorus* and *J. marginatus* may occur together, although *J. biflorus* usually is found in wetter places. It is much more robust than *J. marginatus* with a thicker, more branched, and more knotty underground stem.

11. *Juncus canadensis* J. Gay var. *canadensis*

Map 595

Juncus canadensis J. Gay [G, P & S]

Flowers July–October.

Known only from southern Missouri in Howell (August 13, 1892, *Bush 2598* World's Fair Collection in University of Missouri herbarium) and Bollinger (swampy meadow bordering alder thicket along Wash Creek in narrow valley, T32N, R8E, west part sect. 26, 1½ mi. east of Marquand, September 17, 1954, *Steiermark 77565*) counties.

Ranges from Quebec, Ontario, and Minnesota, south to Georgia, Tennessee, and Louisiana.

12. *Juncus subcaudatus* (Engelm.) Coville & Blake var. *subcaudatus*

Map 596

Juncus subcaudatus (Engelm.) Coville & Blake [G, P & S]

Flowers July–October.

Occurs usually in calcareous, spring-fed, swampy meadows and along spring branches in the Ozark section north to Crawford, Maries, and Camden counties and southwest to Webster and Douglas counties.

Ranges from Georgia and Missouri, north to Massachusetts, New York, Pennsylvania, and Ohio.

Another variety, var. *planisepalus* Fern., occurs in Nova Scotia.

13. *Juncus validus* Coville

Map 597

Flowers July–August.

Occurs in prairie swales and swampy ground.

597 *Juncus validus*598 *Juncus scirpoides* var. *scirpoides*599 *Juncus brachycarpus*

Known only from the unglaciated prairie section in Vernon, Barton, and Jasper counties, and from a wet prairie in Howell County in the Ozark section.

Ranges from Florida to Texas, north to Georgia, Missouri, and Oklahoma.

This is a mostly tall robust species with a large inflorescence of widely spreading branches which support spherical many-flowered heads 10–15 mm. in diameter. The petals and sepals are mainly 4–6 mm. long and much shorter than the narrowly lanceolate slender-tipped capsule.

14. ***Juncus scirpoides* Lam. var. *scirpoides***

Map 598

Flowers June–October.

Occurs in wet sandy ground, prairie swales, and open swampy places, in acid soils. Known from southern Missouri, and locally northeast to St. Louis County.

Ranges from Florida to Texas, north to New York, Pennsylvania, Indiana, Michigan, Illinois, Missouri, and Oklahoma.

Another variety, var. *meridionalis* Buchenau, occurs from Florida north to Long Island, New York.

This species resembles *J. brachycarpus*, from which it may be distinguished by the exserted capsule much exceeding the petals and sepals.

15. ***Juncus brachycarpus* Engelm.**

Map 599

Flowers May–September.

Occurs in wet depressions and draws in prairies, wet meadows, and sandy margins of small streams. Southern and central Missouri, north to St. Louis, Franklin, Callaway, Pettis, Henry, and Vernon counties.

Ranges from Georgia to Texas, north to Massachusetts, Ohio, Ontario, Michigan, Indiana, Illinois, Missouri, and Oklahoma.

16. ***Juncus nodosus* L. Knotted Rush**

Map 600

Flowers July–August.

Occurs on sand bars, sandy banks, and swales along the Missouri River in Jackson County, west-central Missouri (swales, Courtney, July 26, 1904, *Bush* 2138; sandy banks, July 18, 1912, *Bush* 6848; low sandy ground, July 14, 1889, *Bush* 1).

Ranges from Newfoundland to Alaska, south to Virginia, Ohio, Indiana, Illinois, Missouri, Nebraska, Texas, and New Mexico.

A specimen collected from Jasper County (Webb City, *Palmer* 609) and labelled *J. nodosus* is *J. Torreyi*.

17. ***Juncus Torreyi* Coville**

Map 601

Flowers July–October.

Occurs along wet sandy or muddy shores of ponds, sloughs, and small streams, in open ditches, and in swales and wet depressions of prairies and meadows. Throughout Missouri, except not recorded in the southeastern lowland section.

Ranges from Massachusetts and New York to Saskatchewan and Washington, south to Alabama, Missouri, Texas, California, and northern Mexico.

Small-headed forms of this have sometimes been mistaken for *J. nodosus*, *Juncus Torreyi*, and the related *J. nodosus*, *J. acuminatus*, and *J. subcaudatus*, sometimes are found with the inflorescences changed into leafy hornlike clusters of galls.

18. ***Juncus acuminatus* Michx.**

Knotty-leaved Rush

Map 602

Flowers May–August.

Occurs in calcareous, spring-fed meadows, along spring branches, margins of ponds, sloughs, and small streams, wet depressions in prairies and ditches, and open wet ground. Common throughout the Ozark region and in most parts of southern and central Missouri, more locally northward in the state north to Clark, Schuyler, Grundy, and Clinton counties.

Ranges from Georgia to Texas and Mexico, north to Nova Scotia, Maine, Ontario, Michigan, Wisconsin, and Minnesota.

600 *Juncus nodosus* (Knotted Rush)601 *Juncus Torreyi*602 *Juncus acuminatus* f. *acuminatus* (Knotty-leaved Rush)

All the Missouri material has the capsule short-pointed at the summit and is typical *J. acuminatus* f. *acuminatus*. A form with the capsule rounded or ending somewhat abruptly at the summit is known as f. *obtusatus* Herm., but has not been found thus far in the state.

In autumn the fruiting heads of this species often produce leafy offshoots and branches, which are capable of producing new plants directly. This habit is also found in some of the other species, such as *J. debilis*.

19. ***Juncus debilis*** Gray

Map 603

Flowers June–August.

Known only from Ripley County in the southeastern Ozark section (still water of Little Barren Creek, T25N, R1W, west part sect. 28, 1½ mi. southeast of Handy P. O., July 22, 1951, *Steiermark* 72221).

Ranges from Florida to Mississippi, north to Rhode Island, New York, Connecticut, Kentucky, and southeastern Missouri.

In the Steiermark collection the culms are all very weak and slender and nearly all submerged. The inflorescence developed leafy offshoots and branches in this collection.

20. ***Juncus nodatus*** Coville

Map 604

Flowers May–August.

Occurs in wet sandy open ground, wet depressions in upland prairies, borders of ponds, sloughs, slow streams, and ditches, and low wet woods. Found in southeastern Missouri in the lowland section and in the southernmost Ozark counties west to Howell County, and in the extreme western border counties south of the Missouri River, and locally northeast in St. Louis County.

Ranges from Mississippi to Texas, north to Indiana, Illinois, Missouri, and Kansas.

21. ***Juncus diffusissimus*** Buckl.

Map 605

Flowers late May–July.

Occurs in calcareous, spring-fed, swampy meadows, wet rocky banks of small streams, sandy, gravelly, or muddy margins of streams, margins of ponds and sloughs, and wet open places. Restricted to the Ozark and unglaciated prairie sections, extending north to Cape Girardeau, Iron, Crawford, Miller, Benton, Johnson, and Vernon counties.

Ranges from Georgia to Texas, north to Virginia, Indiana, Missouri, and Kansas.

This species is easily recognized by the very long and narrow capsules which are much longer than the short sepals and petals. The inflorescence is widely spreading and much branched, comprising about one-third the height of the plant, and has many small heads of flowers. The plants are usually small, as compared with most of the other species in Missouri, averaging 2–3 dm. in height, but sometimes attaining as much as 5 or more dm.

22. ***Juncus alpinus*** Vill. var. ***fuscescens*** Fern.

Map 606

Flowers July–October.

Known only from sandbars and sandy swales along the Missouri River in Jackson County, west-central Missouri (common along river, Courtney, October 19, 1897, *Bush* 274; sandy bottoms, October 6, 1913, *Bush* 7093; July 26, 1904, *Bush* 2137; sands, August 24, 1910, *Bush* 6166; sandbars, Courtney, October 24, 1897, *Mackenzie* 946).

Ranges from Quebec to Saskatchewan, south to New York, Ohio, Indiana, Illinois, and Missouri.

PLATE NO. 110

603 *Juncus debilis*604 *Juncus nodatus*605 *Juncus diffusissimus*

2. *Luzula* DC. Wood Rush

***Luzula bulbosa* (Wood) Rydb. Wood Rush**

Map 607

Luzula campestris (L.) DC. var. *bulbosa* A. Wood
[P & S]

Luzula campestris (L.) DC. [BB]

Luzula multiflora var. *bulbosa* (Wood) Hermann
[Deam]

Flowers April-June.

Occurs most commonly in acid soils of dry open woodland, usually in oak-hickory or pine-oak-hickory

types, on slopes, upland ridges, or in low level valleys; also occurs on chert, granite, or sandstone glades and dry rocky prairies. Restricted to the Ozark and unglaciated prairie sections of the state, extending north to St. Charles, Warren, Montgomery, Callaway, Boone, Moniteau, Morgan, Henry, and Vernon counties.

Ranges from Florida to Texas, north to Massachusetts, Pennsylvania, Indiana, Illinois, Missouri, and Kansas.

PLATE NO. III

Fam. **LILIACEAE** (Lily Family)

The treatment of this family follows the traditional one maintained by Fernald in the eighth ed. of *Gray's Manual* and by Gleason in the *New Britton and Brown Illustrated Flora*.

Some botanists have followed a system proposed by Hutchinson in his *Families of Flowering Plants* (vol. 2: 129 and following pages, 1934) to include in the Liliaceae only those plants in which the inflorescence is not subtended by bracts or a spathe. This would exclude *Allium* and *Nothoscordum* among those genera found in Missouri. Also some botanists now exclude *Yucca* from the Liliaceae, placing it and *Agave* in a separate family, Agavaceae. *Smilax* is sometimes removed to a separate family, Smilacaceae.

Evidently, then, at the present time there is no general agreement. While admitting some justification for the splitting up of the Liliaceae, and the realignment of some of the genera into the Amaryllidaceae, the present treatment follows the Engler-Prantl arrangement, at present adopted by many botanists.

- a. Leaves absent at time of flowering or fruiting 7. **ALLIUM TRICOCCUM**
- a. Leaves present at time of flowering or fruiting b
- b. Leaf-like parts (really branchlets) thread-like, the true leaves reduced to tiny scales . . . 17. **ASPARAGUS**
- b. Leaves not thread-like c
- c. The main leaves arising at the base or crowded near the very base of the plant, a leafless or nearly leafless naked stem (scape) supporting the flower, flowers, or fruits (do not judge any reduced green leaf-like bracts as leaves here) d
- d. Only 2 leaves present at flowering or fruiting time (only 1 when sterile) on 1 plant; plant with only 1 flower, 1 bud, or 1 fruit 11. **ERYTHRONIUM**
- d. Without the above combination; usually 3 or more leaves present at flowering or fruiting time, or, if 2 leaves present, the flowers blue; or plant with 2 or more flowers, buds or fruits . . . e
- e. Lowest leaves near ground very broad, 6 cm. or more broad; leaves at base of plant and those on stem broadest at or above the middle, oblanceolate to elliptical; axis of inflorescence somewhat hairy with short fine hairs 4. **VERATRUM**
- e. All leaves linear, ribbon- or grass-shaped, at most 4 cm. broad f
- f. Leaves with thread-like fibers separating loose from the margins (more prominent during spring and fall months); leaves thick and tough, hard to tear; plants rising from a strong woody base; inflorescence 30–200 cm. long; flowers white, large, 3.5–7 cm. long, 2–3 cm. wide; fruit a large capsule 2–7 cm. long; seeds large, black, 6–13 mm. long . . . 16. **YUCCA**
- f. Without the above combination of characters g
- g. Flower orange or yellow, 10–13 cm. long, 10–12 cm. wide; roots a cluster of thickened tubers; flowering stem (scape) 50–200 cm. tall 9. **HEMEROCALLIS**
- g. Without the above combination of characters h
- h. Flowers or fruits arranged in an umbel (flower stalks arising from about the same place at the same level) i
- i. All parts of plant with an onion or garlic odor; flowers usually some shade of pink, rose, lavender, or rarely white; flowers or fruits usually 8–50 or more in one umbel, or sometimes changed to little bulblets instead of flowers; ovules or seeds 1–2 in each cell of ovary or fruit 7. **ALLIUM**
- i. No part of plant with an onion or garlic odor; flowers white to greenish-white, usually 3–8 (sometimes up to 12) in one umbel, never changed to little bulblets; ovules or seeds 4–10 in each cell of ovary or fruit . . . 8. **NOTHOSCORDUM**
- h. Flowers or fruits arranged in a raceme, or panicle, or solitary, the flower- or fruit-stalks arising along the elongated axis at different levels j
- j. Perianth of flower almost globe-shaped or short tube-shaped, its segments united at least to the middle or more; flowers longer than their stalks (pedicels), in a dense raceme with little space between the flowers; low plants at most 2.5 dm. tall when in flower 15. **MUSCARI**
- j. Perianth with its parts divided or separate nearly or all the way to the base; flowers often shorter than, but also longer than their stalks in looser racemes or panicles, with much space at least between the lower flowers; low or tall plants, sometimes up to 15 dm. tall k
- k. Open flowers and buds or fruits only 1–12 to an inflorescence l

1. Perianth of flower deep blue; pedicels (the individual flower-stalks) mostly 2-9 mm. long; bracts at base of pedicels very short, 2-4 mm. long 13. SCILLA
1. Perianth of flower white with a green stripe on the outside; pedicels 10-60 mm. long; bracts at base of pedicels 10-40 mm. long 14. ORNITHOGALUM
- k. Open flowers and buds or fruits mainly 20 or more to an inflorescence m
- m. Style 1; perianth usually shades of lavender or blue; fruit showing 1 beak or point at summit 12. CAMASSIA
- m. Styles 3; perianth white, greenish-yellow, or green-and-purple; fruit showing 3 beaks or points at summit n
- n. Bracts at the base of the pedicels (the individual flower-stalks) 10-20 mm. long; perianth 6-12 mm. long; 1-2 dark or colored spots (glands) at or above base of each perianth segment 3. ZIGADENUS
- n. Bracts at the base of the pedicels small and inconspicuous, about 2 mm. long; no spots or glands present on perianth segments o
- o. Pedicels (stalks) of flowers none or at most 2 mm. long at flowering time, much shorter than the flowers; perianth segments of flower narrowly pointed (acuminate) at tip; mature fruit with 3 short beaks at tip 2. STENANTHIUM
- o. Pedicels (stalks) of flowers 15 mm. or more long, much longer than the flowers; perianth segments of flower rounded at summit; mature fruit with conspicuous 3 horn-like lobes 1. AMIANTHIUM
- c. The main leaves scattered alternately on the stem or in 1. or more whorls (circles) of 3 or more p
- p. Leaves in 1, 2, or more whorls (circles) of 3 or more leaves q
- q. Leaves in 1 whorl of 3 leaves 21. TRILLIUM
- q. Leaves in 2 or more whorls r
- r. Leaves in 2 whorls 20. MEDEOLA
- r. Leaves in 6-11 whorls 10. LILIUM MICHIGANENSE
- p. Leaves scattered alternately along the stem s
- s. Axis of inflorescence or upper part of stem more or less hairy or downy with some type of hairiness t
- t. Flowers large and showy, 75-100 cm. long, the perianth segments 12-25 mm. wide; dark small bulblets in the upper part of the stem at the base of the leaves 10. LILIUM TIGRINUM
- t. Flowers much smaller, the perianth segments only 5-13 mm. long, 2-5 mm. wide; no bulblets present at the base of the leaves u
- u. Plants of open prairies, meadows, and along railroads; all the leaves broadly linear, broadly ribbon- or grass-like, nearly the same width throughout, 1.5-3 cm. wide; 2 dark glands on the inside of the base of each perianth segment 5. MELANTHIUM
- u. Plants of wooded slopes; lowest leaves near ground very broad, 6 cm. or more broad; leaves at base of plant and on stem oblanceolate to elliptical, broadest at or above the middle; no glands at the base of the perianth segments 4. VERATRUM
- s. Axis of inflorescence and stem glabrous (without hairs) v
- v. Base of leaf completely encircling or growing around the stem 6. UVULARIA GRANDIFLORA
- v. Base of leaf not encircling the stem w
- w. Leaves narrowed to a short or long petiole (stalk of leaf); climbing or tough- or woody-stemmed plants with or without tendrils or spines, or, if soft-stemmed herbs, the leaves with a network of veins connecting the main nerves 22. SMILAX
- w. Leaves lacking a petiole, attached directly to main stem; soft-stemmed herbs, not climbing, not woody, not spiny and without tendrils; or leaves all parallel-veined, lacking a network of connecting veins x
- x. Mature plant forking or branching at the 1st or 2nd leaf; flower and fruit solitary, the flower pale yellow or cream-colored and 12-25 mm. long, the fruit a sharply 3-angled capsule 6. UVULARIA SESSILIFOLIA
- x. Without the above combination; mature plant with a simple unbranched stem; flowers and fruits not as above y
- y. Flowers or fruits produced from the sides of the stem or hanging below the leaves 19. POLYGONATUM
- y. Flowers or fruits at the top of the stem z
- z. All parts of plant with an onion or garlic odor; flowers or fruits arranged in an umbel (flower stalks arising from about the same place at the same level), sometimes the flowers changed to little bulblets 7. ALLIUM

806. *Juncus alpinus* var. *fuscescens*

807. *Luzula bulbosa* (Wood Rush)

808. *Amianthium muscaetoxicum* (Fly Poison)

- z. No part of plant with an onion or garlic odor; flowers or fruits arranged in a raceme or panicle, the flower- or fruit-stalks arising along the elongated axis at different levels I
1. All the leaves linear, ribbon- or grass-like, 4–15 mm. wide, about the same width from one end to the other, 25–40 times or more longer than broad; fruit a capsule 2. *STENANTHIUM*
1. Leaves oblong, oval, or lanceolate, the larger ones 10–90 mm. wide, broader near the middle or base, 3–7 times longer than broad; fruit a berry 18. *SMILACINA*

1. *Amianthium* Gray Fly Poison

***Amianthium muscaetoxicum* (Walt.) Gray**
Fly Poison Map 608
Flowers May–July.

In acid soils of sandy or cherty ground of low wooded slopes or in level ground of small valleys. Southern Missouri in the Ozark region, east to Butler County, west to Greene County, and north to Reynolds and Greene counties.

Ranges from Florida to Mississippi, Arkansas, and Oklahoma, north to southern New York, Pennsylvania,

West Virginia, Kentucky, and Missouri.
The leaves and underground bulb are poisonous, especially so to cattle and sheep.

The flowers are white at first, soon turning yellow-green or eventually green with purplish color, and on one inflorescence the various stages of flowering show a striking color variation, the older lower flowers having already turned green, while the freshly open flowers higher up towards the top are white. The leaves spread outward and arch downward.

2. *Stenanthium* Gray

Stenanthium gramineum* (Ker) Morong var. *gramineum Featherbells Map 609
Stenanthium gramineum (Ker) Morong [G, P & S]
Stenanthium gramineum f. *robustum* (Wats.) Palm. & Steyerl. [of P & S], not *Stenanthium gramineum* var. *robustum* (S. Wats.) Fern. [G]
Flowers mid-June–September.

Occurs in moist rocky woods, rich wooded slopes, along and at the base of wooded bluffs, open banks along railroads, and occasionally in open thickets;

most frequent in acid soils. Throughout Missouri, but commonest in the Ozark section; locally north in Audrain, Linn, and Harrison counties.

The whitish or greenish-white flowers are produced during summer on an elongated panicle usually 4–8 dm. tall with drooping or spreading lateral branches. The plant itself attains a height of 1.5 meters, the lowest section of the stem being 4–10 mm. thick. The long, ribbonlike, pale green leaves are crowded toward the base in the lower third of the plant. The

609 *Stenanthium gramineum* var. *gramineum* (Featherbells)610 *Zigadenus elegans* (White Camas)611 *Zigadenus Nuttallii* (Death Camas)

leaves, which in Missouri material vary mainly from 7–15 mm. wide, have a somewhat corrugated surface because of the prominently raised ribs. Another variety, var. *robustum* (Wats.) Fern., not known in Missouri, has the larger leaves mainly 10–30 mm. wide, the ribs more depressed and sunken in the leaf tissue, crowded up to the main branches of the panicle, and

the lowest section of the dried stem 7–15 mm. thick. Plants which have been transplanted to the author's wildflower garden are still living after ten years, but show an irregularity in flowering, some years producing only a leafy basal rosette, other years flowering. New plants have been produced from extensions sent out underground by the bulbous base of the plant.

3. *Zigadenus* Michx. Death Camas

- a. Plants of wet crevices of north-facing limestone bluffs, flowering in late June–early August; perianth segments 8–12 mm. long; gland at base of perianth segment 2-lobed; mature fruiting capsule 13–22 mm. long; bracteoles 5–13 mm. long; pedicels 4–30 mm. long 1. *Z. ELEGANS*
- a. Plants of dry limestone open woods and glades, flowering in May; perianth segments 6–8 mm. long; gland at base of perianth segment not lobed; mature fruiting capsule 13–16 mm. long; pedicels 10–26 mm. long in flower, 17–45 mm. long in fruit 2. *Z. NUTTALLII*

1. *Zigadenus elegans* Pursh White Camas

Map 610

Flowers late June–early August.

Occurs in moist crevices of north-facing limestone bluffs. Very rare and known only from the southern Ozark region at Jam-up Bluff in Shannon County, along the Gasconade River in Pulaski County (by Peterson Cave, sect. 8, 5 mi. northwest of Waynesville, August 24, 1937, *Steyermark 25263*), and along Indian Creek in Douglas County (Holy Cliff and vicinity, T26–27N, R11W, sect. 4 and 33, 3½ mi. northeast of Topaz, July 19, 1937, *Steyermark 23345*).

Ranges from Alaska to Arizona and New Mexico, east to Manitoba, Minnesota, Iowa, and Missouri.

This is another one of the remarkable northern species of plants apparently isolated in the Ozarks after the retreat of one of the stages of Pleistocene ice and now surviving at one of its southernmost outposts as a relict. At the Jam-up locality this species occurs with an assemblage of other remarkable northern relict species, such as *Galium boreale* var. *hyssopifolium* and *Campanula rotundifolia*.

An alkaloid, zygadenine, contained in this and other species of the genus, is the source of a poison which may produce harmful effects on cattle, horses and sheep, especially when the fresh leaves, stems, or flowers are eaten. The seeds are considered quite poisonous also. Poisoning may occur among children if the bulbs are eaten.

2. *Zigadenus Nuttallii* Gray Death Camas

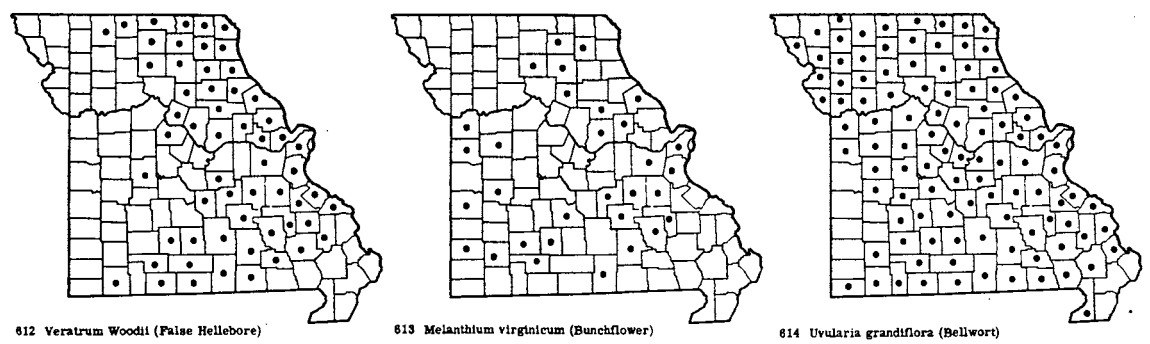

Map 611

Flowers May.

Known only from Oregon County in the southern Ozark region, where it occurs at 'The Narrows' on a dry narrow limestone open wooded ridge or glade above a bluff above Blue Spring along Fredericks Fork west of Calm (May 11, 1935, *Steyermark 18920*; July 13, 1933, *Palmer & Steyermark 41667*).

Ranges from Tennessee, Missouri, and Kansas to Oklahoma and Texas.

At the Missouri locality it occurs with *Arenaria patula* and *Melica nitens*.

4. **Veratrum** L. False Hellebore

Veratrum Woodii Robbins False Hellebore
Map 612

Flowers July–September.

Occurs usually on north- or east-facing wooded limestone slopes in the Ozark region, and on rich wooded slopes in northern Missouri. Found in the Ozark section of the state northward in the eastern half of Missouri, west to Harrison, Linn, and Howard counties, and south of the Missouri River west to Cooper, Benton, Pulaski, Webster, Christian, and Barry counties.

Ranges from Ohio and Iowa, south to Missouri and Oklahoma.

The plant is commonly found in the eastern half of the state, but is most often seen in the sterile leafy condition, attracting much attention by its broad, handsome, plaited basal leaves. These root leaves emerge in early spring. Flowering appears to be very irregular, some seasons passing without any flowering taking place. At various localities where flowering was

observed, only a small percentage of the plants bore flowering stalks. On other occasions a greater percentage of plants had flowers. On still other occasions no plants were observed in flower. Plants in flower attain a height of 1.3–1.8 meters. The perianth of the flowers is dark maroon, fading to dull greenish with purple.

At the author’s wildflower garden where two plants have been growing for eleven years, one has flowered twice during this time, the first time waiting seven years before flowering, the second time flowering three years later. The second plant has flowered only once, this during the same year as the first plant.

Several alkaloids are found in related species which are a source of poison. In Europe a species of *Veratrum* is used as an insecticide. The green shoots and seeds, when eaten, sometimes poison chickens, and an overdose of drugs containing *Veratrum* may cause poisoning symptoms. Ordinarily, most grazing animals avoid the plant because of its sharp burning taste.

5. **Melanthium** L. Bunchflower

Melanthium virginicum L. Bunchflower
Map 613

Flowers about June 10–early August.

Occurs in prairies, wet meadows, thickets, and wet ground below bluffs. Scattered throughout southern and central Missouri, and north of the Missouri River in the eastern half of the state west to Adair and Linn counties.

Ranges from Florida to Texas, north to New York, Ohio, Indiana, Illinois, and Iowa.

Horses have been reported being poisoned after having eaten hay containing seeds of this species.

The broadly ovoid to ovoid-pyramidal inflorescence is very showy with cream-colored flowers which turn to green and purplish shades with age. The plant itself usually attains a height of 1–1.5 meters.

6. **Uvularia** L. Bellwort

| Base of leaf not encircling nor growing around the stem | 2. U. SESSILIFOLIA |

615 *Uvularia sessilifolia* (Small Bellwort)616 *Allium tricoccum* (Wild Leek)617 *Allium sativum* (Garlic)

1. ***Uvularia grandiflora* Sm.** Bellwort Map 614
Flowers April–May.

Occurs in rich or rocky soil of woodland, on steep slopes or level alluvial valleys. Throughout Missouri, except absent from some of the counties of the unglaciated southwestern prairie section and southeastern lowland section.

Ranges from Quebec to North Dakota, south to Georgia, Arkansas, and Oklahoma.

The starchy roots may be cooked as a vegetable.

2. ***Uvularia sessilifolia* L.** Small Bellwort Map 615
Flowers April–May.

Occurs in rich or alluvial soils in mostly level ground of low woods along streams, occasionally along north-facing wooded bluffs. Scattered in the north-eastern and north-central counties of the state south

to Lincoln, Audrain, and Boone counties, west to Harrison, Linn, and Chariton counties, and locally in Jasper County, southwestern Missouri (rocky wooded north-facing hillside along bluff of Turkey Creek, 1/8 mi. east of 'Castle Rock,' 1 mi. north of Joplin, April 29, 1949, *Palmer 18613*). The isolated occurrence of the species in Jasper County, the only station south of the Missouri River in the state, may be regarded as a probable relict survivor from Pleistocene times, but it is difficult to explain why it has not survived in other southern sectors of the Ozarks.

Ranges from New Brunswick and Ontario to North Dakota, south to Georgia, Alabama, Tennessee, Missouri, and Arkansas.

The young shoots of this species are reported to be eaten, when cooked, as a substitute for asparagus, and it is supposed that the young shoots of *U. grandiflora* can be similarly used.

7. ***Allium* L.** Onion, Garlic, Leek

- a. Leaves absent at flowering time; leaves found during spring and with elliptical or elliptic-lanceolate leaf-blades 3–10 cm. wide with a petiole 1. *A. TRICOCIMUM*
- a. Leaves present at flowering time; leaves linear or ribbon-like, without a petiole b
- b. Stems bearing leaves 1/3 to 1/2 way up the stem c
- c. Leaf-blades 5–15 mm. wide, flat, ribbon-like; base of stem often dark red-purple; perianth of flowers greenish, whitish, or pink, its segments lanceolate and long-pointed (acuminate) 2. *A. SATIVUM*
- c. Leaf-blades 1.5–3 mm. wide (in dried condition), hollow, terete (like a quill of a feather or porcupine) or nearly terete (convex on one side, plane or concave on other side); base of stem usually bluish- or gray-green; perianth of flowers pink, lavender, rose-purplish, or occasionally white or greenish, its segments obtuse to somewhat short-pointed (acutish) 3. *A. VINEALE*
- b. All the leaves at the base or nearly so d
- d. Leaves terete (like the quill of a feather or porcupine) or nearly so, hollow e
- e. Stem enlarged or inflated somewhere below the middle; leaves spreading or drooping; bulb globose or ball-shaped, much thicker than the stem; pedicels (the individual flower stalks) much longer than the greenish white to lilac flowers 4. *A. CEPA*
- e. Stem not inflated, of the same slender diameter throughout; leaves erect; bulb oblong-ovoid, scarcely thicker than the stem; pedicels shorter than the pink or rose-purple flowers 5. *A. SCHOENOPRASUM*
- d. Leaves flat, not hollow f

- f. The umbels of flowers mostly producing little bulblets, the actual flowers and fruits few or none 6. *A. CANADENSE*
- f. The umbels of flowers producing flowers and fruits only g
- g. Flowering mainly late April-late June; outer coats of the bulb with a criss-cross mat or network of coarse hair-like fibers; sepals and petals longer than the stamens; no horns or triangular projections produced from any of the 3 valves or cells of the ovary or fruit 7. *A. MUTABILE*
- g. Flowering mainly July-November; outer coats of the bulb only vertically nerved and membrane-like, not with any network of coarse fibers; sepals and petals shorter than the eventually exerted stamens; each of the 3 valves or cells of the ovary or fruit producing 2 horns or triangular projections at the summit (6 all together) h
- h. The main supporting stem (scape) of the inflorescence arched or hooked at summit; the umbel of flowers drooping or nodding 8. *A. CERNUUM*
- h. The main supporting stem (scape) of the inflorescence erect to the tip, not arched or hooked at summit; the umbel of flowers erect 9. *A. STELLATUM*

1. **Allium tricoccum** Ait. Wild Leek Map 616
Flowers mid-June-July.

Occurs mainly on rich soils of north-facing wooded slopes or limestone bluffs. Northern, central, and eastern Ozark region west to Osage, Dent, Reynolds, and Carter counties.

Ranges from New Brunswick and Quebec to Minnesota, south to Georgia, Tennessee, Illinois, and Missouri.

The leaves appear in earliest spring, resembling tulip leaves in size and shape. They disappear at the time of flowering. In late May the inflorescence is still in bud stage, and not until later in June do the whitish flowers actually open. The capsule ripens later in the summer, exposing the 3 steel gray, bulletlike seeds.

Most of the Missouri plants of this species have the upper surface of the leaf-blade a rich olive- or grass-green, the lower surface paler green, not shining on either side and tapering into a wine purple or reddish-purple petiole; the broadly elliptical, elliptic-oblong or elliptical-lanceolate blades are quite broad, averaging mainly 4-9 cm. wide. The flowering scapes of such plants are also purple or red-purple. This is in contrast to the plants of other sections of the country, especially in the northern and eastern states, where the tendency is towards specimens with narrower leaf-blades 2-4 cm. wide, darker and deeper green and shining on both sides and without any purple or reddish-purple at the base. The scapes in these plants are usually pale green. When grown together, the plants with purple in the petiole appear above the ground a week to ten days earlier than those with no purple color. These two races have been discussed in a paper by Clarence R. Hanes and Marion Ownbey (Rh. 48: 61-63. 1946), but no names have been given as yet to these plants which are being studied by Drs. Ownbey and Aase. Plants from the Missouri Ozarks brought north to the author's wildflower gar-

den have borne out the observations made by Dr. Ownbey, and can easily be distinguished from the other plants of *A. tricoccum* native to northern Illinois by the earlier appearance of the leaves, their broader, darker green color with purple petioles and scapes.

The young leaves may be used as a seasoning in soups or cooked into an onion soup. They also may be cut up in salads.

2. **Allium sativum** L. Garlic Map 617
Flowers late May-July.

Occurs in waste ground, along roadsides and railroads, fields, meadows, thickets, and grassy places. Scattered in various parts of Missouri and probably more common than the records indicate.

Native to Eurasia; introduced into the United States where it ranges from New York to Indiana, south to Kentucky, Tennessee, and Missouri.

The ribbonlike gray- or silvery-green leaves are smooth and handsome in early spring when the species is seen in best foliage condition. The stems are usually dark purple-red at the base. Usually, many plants are found growing together.

It can become a bad pest if allowed to become established in cultivated areas.

3. **Allium vineale** L. Field Garlic Map 618
Flowers May-July.

Occurs in fields, meadows, thickets, borders of woods and streams, along railroads, and waste ground. Missouri material is represented by two variations:

- Umbels with bulblets mixed with normal stalked flowers 3a. *A. VINEALE* f. *VINEALE*
- Umbels consisting entirely of bulblets. 3b. *A. VINEALE* f. *COMPACTUM*

3a. **Allium vineale** L. f. **vineale** Map 618

Common over the southern and central portions of the state and locally north to Marion and Living-

618 ■ *Allium vineale* f. *vineale* (Field Garlic)
618 □ *Allium vineale* f. *compactum*

619 *Allium Cepa* var. *viviparum* (Onion)

620 *Allium Schoenoprasum* var. *Schoenoprasum* (Chives)

ston counties. This is the commoner of the forms encountered.

Native of Europe; introduced into the United States, where it ranges from Georgia to Arkansas, north to Massachusetts, New York, Ohio, Michigan, Illinois, Missouri, and Kansas.

The leaves are bluish-green. They may be terete or subterete with one side rounded and convex and the other side plane to concave or sunken.

This species is responsible for contaminating milk and other dairy products with a garlic flavor in the late winter and early spring months. Not only is the flavor transmitted by the actual eating of the plant by cows, but by inhaling the volatile oil emanating from the fresh plants, the same effect is produced. It is among the strongest-flavored of the strong-flavored species, and produces a burning sensation if tasted.

It is also a bad weed in wheat-producing areas, and, when bulblets become harvested with the wheat, they must be removed before the wheat is acceptable for milling. It has been suggested that this species may be used to advantage as a spring pasture for meat-producing beef and sheep.

Allium vineale is sometimes confused with *A. oleraceum* L., Wild Garlic, which has not been recorded thus far from Missouri. *Allium oleraceum* has the leaf-blades flattened toward the summit instead of nearly terete and hollow, the bulbs are simple and not crowded or with older or smaller secondary side bulbs, the filaments of the flowers are slender and without appendages, whereas in *A. vineale* they are dilated at the base, with the upper half 3-cuspidate or divided into three linear divisions or appendages; finally, in

A. oleraceum there are two leafy, elongated, linear bracts forming the spathe which persist below the umbel, whereas in *A. vineale* there is only one thin transparent bract which quickly falls away from the umbel.

3b. *Allium vineale* f. *compactum* (Thuill.)

Aschers.

Map 618

Known only from Howell County and Livingston County (along ditch, partially shaded, T58N, R24W, sect. 14, 3.3 mi. north and 1.2 mi. west of Chillicothe, June 15, 1950, *Sparling* 57).

4. *Allium Cepa* L. Onion

Map 619

Flowers late May–July.

Native of southwestern Asia. Commonly cultivated in the United States and rarely escaped to waste ground.

Allium Cepa var. *Cepa* was listed by Daniels in his *Flora of Columbia* [as *Allium Cepa*], but no specimen is extant.

Allium Cepa var. *viviparum* Metz, the Top Onion, has been found in St. Louis County (St. Louis, on the free place between the signal box at Davis Street Junction and the grain elevator on Mo. Pacific Railroad, May 20, 1957, *Muehlenbach* 1165). It differs from the ordinary onion in having a small undeveloped bulb and the umbel of the inflorescence developing bulblets. These latter are used for propagating purposes. In *Allium Cepa* var. *Cepa* the underground bulb is large and well-developed, recognized when mature as the familiar common onion, and the large umbel is filled with a dense cluster of numerous flowers borne on upwardly curving pedicels.

There have been occasional reports of horses being

Plate no. 113. 1. *Uvularia grandiflora*, $\times \frac{2}{7}$; a. Flowering plant; b. Fruiting plant; Details from Small, The New York Botanical Garden. 2. *Allium tricoccum*; a. 621 *Allium canadense* (Wild Garlic)622 *Allium mutabile*623 *Allium cernuum* (Nodding Wild Onion)

poisoned from eating *A. Cepa*, but such poisoning appears to have resulted from the eating of partly decayed bulbs.

5. ***Allium Schoenoprasum* var. *Schoenoprasum*** (L.) Hartm. Chives Map 620
Flowers June–August.

Known only as an escape in Lawrence and in St. Louis (St. Louis, June 30, 1910, *Earl E. Sherff*) counties.

Native of Europe. Commonly cultivated, but rarely escaped to waste ground.

The stem is only 2–5 dm. tall, the plants occurring in dense clumps from crowded tiny bulbs. The numerous leaves nearly equal or sometimes are longer than the stems. The many pink to rose-colored flowers are borne in a dense hemispherical umbel.

This is a well-known plant used for seasoning cheese, soups, relishes, and salads.

6. ***Allium canadense* L.** Wild Garlic Map 621
Allium canadense L. var. *canadense* [Ownbey & Aase]
Flowers early May–July.

Occurs in moist open woodland, usually in level ground of valleys along streams, alluvial banks and slopes, thickets, meadows, edge of bluffs, prairies, open fields, along roadsides, railroads, and waste ground. Throughout Missouri and doubtless in every county.

Ranges from Florida to Texas, north to New Brunswick, Quebec, Ontario, Wisconsin, and Minnesota.

The flowers, which are usually pink or lilac and pink, rarely whitish, are few to an umbel.

Ownbey and Aase (Res. Stud. State College Wash. Monogr. Supp. 1, vol. 23, no. 4: 1–106. 1955) have attempted to group into one species, *A. canadense*, with several varieties, all the native species in Missouri having coarsely anastomosing or reticulate criss-cross fibers of the outer coats of the bulb. They maintain *A. canadense* var. *canadense* as an asexual variety, with most or all of the flowering pedicels replaced by bulblets, for the plants which have previously ordinarily passed as *A. canadense*. However, since the Mis-

souri material falls clearly into what many other botanists would consider distinct and easily recognizable species, I am treating *A. canadense* in the category of a species rather than as a variety. Seen not only in the field, but grown in the garden, the Missouri plants do not intergrade, but retain the clearly marked characters which distinguish them. Shinnars, likewise, in his *Spring Flora of the Dallas-Fort Worth Area, Texas* (pp. 93–94. 1958) has preferred the status of species rather than variety for a similar situation existing among the Texas constituents of the same group related to *Allium canadense*.

Like *Allium vineale*, *A. canadense* is also responsible for giving an onion flavor to milk and other dairy products in the late winter and early spring months when it is eaten by cows grazing the valley woodlands and meadows.

Unlike the strong-scented *A. vineale*, however, the bulbs of *A. canadense* are considered to have a rather sweet flavor and are edible, while the bulblets of the inflorescence can be pickled and eaten as such. The entire plant, before it reaches the flowering stage, can be boiled and made into a soup, while the young fresh leaves can be cut up to season salads or as a garnish for flavoring meats, cheese, and spaghetti dishes.

7. ***Allium mutabile* Michx.** Map 622
Allium canadense var. *mobile* (Regel) Ownbey [Ownbey & Aase]
Allium microscordion Small
Allium canadense var. *lavendulare* (Bates) Ownbey [Ownbey & Aase]
Allium acetabulum (Raf.) Shinnars var. *lavendulare* (Bates) Shinnars
Flowers late April–late June.

Occurs chiefly on limestone glades and prairies, sandstone exposures, upland cherty openings above bluffs, and along railroads throughout central and southern Missouri in the Ozark and unglaciated prairie sections, northward in glaciated prairie mainly in

the western sector to Grundy, Daviess, Clinton, and Platte counties, and locally east in Ralls County.

Ranges from Florida to Texas, north to North Carolina, Missouri, and Nebraska.

This is an attractive plant with numerous flowers on elongated pedicels. The flowers are usually some shade of rose, pink, or lilac, but also vary to white. Plants here referred to *A. mutabile* are treated by Ownbey and Aase (loc. cit. pp. 29, 45-50, 51-55) as two varieties. Normally, the plants are robust and average 3-5 dm. tall (varying from 2-6) with rather thickened, rigid pedicels. Infrequently, in some of the southwestern counties, occasional plants are found which are more slender, usually 1-2.5 dm. tall (varying to 5), and with very slender, threadlike pedicels. Ownbey and Aase consider the taller and more robust plants with stouter pedicels as *Allium canadense* var. *lavendulare*, while the shorter plants with slender, filiform pedicels are treated as *A. canadense* var. *mobile*. They assign the var. *mobile* to collections from Howell, Taney, Wright, Jasper, and McDonald, all in southwestern Missouri. The var. *lavendulare* they consider to be the widespread type. Both varieties are maintained by them as sexually developed varieties having all the flowering pedicels bearing flowers and fruits as contrasted to the bulblet-bearing, mostly asexual var. *canadense*. However, as stated under *A. canadense*, the Missouri material appears to be clearly recognizable as two ordinarily distinct species, which can be distinguished both in the field and in the garden.

The slender, shorter plants with more filiform pedicels referred by Ownbey and Aase to var. *mobile* are considered in this flora as intermediates and possibly hybrids between *A. mutabile* and *A. canadense*. The specimen from McDonald County (barrens, Noel, May 4, 1909, *Bush 5613*), labelled *A. Helleri* by Bush and previously catalogued as *Allium Nuttallii* Wats. [= *A. Drummondii* Regel] by Palmer and Steyermark (*Annot. Cat. Fl. Pl.* p. 501. 1935) is one of these smaller individuals, which Ownbey and Aase would place under *A. canadense* var. *mobile*.

8. *Nothoscordum* Kunth False Garlic

Nothoscordum bivalve (L.) Britton

False Garlic, Crow Poison Map 625
Flowers late March-May and October-November.

Occurs on rocky glades of limestone, chert, granite, or sandstone, sandy open alluvial soils along streams, rocky exposed ledges, upland open wooded areas, and on upland or river bottom prairies. Southern and central Missouri, locally north to Ralls, Audrain, Linn,

8. *Allium cernuum* Roth

Nodding Wild Onion Map 623
Flowers July-September.

Occurs mostly along rocky wooded ledges of bluffs and shaded slopes. Ozark region of southern and east-central Missouri, north to Jefferson, Franklin, and Pulaski counties, west to Polk and Greene counties.

Ranges from New York to Minnesota and British Columbia, south to Georgia, Tennessee, Missouri, Texas, and Arizona.

Plants with white petals and sepals occur infrequently (*Steyermark 19331* from Pulaski County).

Dr. Ownbey has referred all the Missouri specimens to *Allium stellatum*, but those plants having the summit of the peduncle hooked with drooping umbels I have placed in *A. cernuum*.

9. *Allium stellatum* Fraser Wild Onion Map 624 Flowers July-November.

Occurs on limestone glades and exposed ledges of bluffs. Restricted to the unglaciated Ozark area in southern and central Missouri north to Lincoln, Boone, Pettis, and Henry counties.

Ranges from Ohio and Ontario to Saskatchewan, south to Illinois, Missouri, Arkansas, Kansas, and Texas; introduced in Indiana.

This species has showy rose to pink flowers and does well in cultivation when grown in a sunny exposure with a limey rocky soil. Flowering as it does late in the season it is a welcome addition to a rock garden.

Excluded species

Allium Drummondii Regel

Allium Nuttallii Wats. [P & S]

Recorded by Palmer and Steyermark (*Annot. Cat. Fl. Pl.* p. 501. 1935) from McDonald County, the collection (*Bush 5613*) is here referred to *A. mutabile* Michx. as a small slender specimen of that species. It is placed by Ownbey and Aase under *A. canadense* var. *mobile* (Regel) Ownbey.

and Livingston counties; absent from most of the southeastern lowland section where found only on Crowley Ridge.

Ranges from Florida to Texas and Mexico, north to Virginia, Ohio, Indiana, Illinois, Missouri, and Nebraska.

Plants often flower again in fall, following late rains and warm temperatures.

624 *Allium stellatum* (Wild Onion)625 *Nothoscordum bivalve* (False Garlic)626 • *Hemerocallis fulva* var. *fulva* (Orange Day Lily)
626 □ *Hemerocallis fulva* var. *Kwanso* (Double Orange Day Lily)

9. *Hemerocallis* L. Day Lily

Hemerocallis fulva L. Orange Day Lily

Map 626

Flowers late May–August.

Commonly cultivated, and often escaped and well established on moist wooded banks along streams, alluvial thickets, fields, roadsides, and railroads. Scattered over the state.

Native to Eurasia; introduced into North America, where it has spread from New Brunswick to Ontario, south to North Carolina, Tennessee, Missouri, Kansas, and Nebraska.

The plant spreads only by its tuberous roots in North America, as it is not known to produce seed naturally.

Two variations are encountered in Missouri:

Flowers with normal 6 perianth segments . . .

H. FULVA var. *FULVA*

Flowers double, with more than 6 perianth segments to a flower . . .

H. FULVA var. *KWANSO*

Hemerocallis fulva L. var. *fulva*

Map 626

This is the common variation encountered with large orange-brick red flowers, usually with an apricot-colored line down the middle of each petal. Plants usually form large clumps.

Hemerocallis fulva var. *Kwanso* Regel Map 626

This double-flowered variation is known thus far as an escape only in St. Louis County (St. Louis, Carrie Avenue freight yard of Rock Island R. R. in

northeast corner of the yard, July 4, 1957, *Muehlenbach* 1257).

This has been found naturalized in Virginia. It is introduced from Asia.

Var. *Kwanso* is a less double-flowered variation than var. *flore pleno*.

Another species of *Hemerocallis*, *H. flava* L., the yellow day lily or lemon lily, is commonly cultivated and sometimes becomes established away from cultivation, but no definite records are known in Missouri of its having become naturalized.

For many years *Hemerocallis fulva* and *H. flava* had been the only day lilies in cultivation. With the pioneer work by Dr. A. B. Stout, followed by other workers, breeding of day lilies and development of new strains have increased the numbers of available horticultural types now cultivated into the thousands. None of these, however, have been found escaped from cultivation, only *H. fulva* var. *fulva* and var. *Kwanso* having been recorded.

The plant may be prepared for food in various ways. Fully grown flower buds or open flowers, browned in oil or butter in a batter of eggs, flour, and milk, are considered as a tasty dish. Flowers soaked in water are added in final stages of cooking to soups, meats, and noodles to impart a pleasant flavor as well as substance to the dish. The tuberous roots, boiled in salted water, are reported to possess the flavor of corn and salsify.

1. *Lilium michiganense* Farw. Michigan Lily

Map 627

Lilium canadense L. ssp. *michiganense* (Farwell) Boivin & Cody

Lilium canadense ssp. *michiganense* f. *uniflorum* (Farwell) Boivin & Cody

Lilium michiganense f. *uniflorum* (Farwell) Wherry

Lilium michiganense f. *peramoenum* (Farwell) Stoker

Lilium superbum [of BB], not L.

Flowers mainly June 20–July 12.

Occurs in prairie swales, swampy meadows, low woods in valleys, low wooded slopes, and prairie remnants along railroads. Throughout Missouri, except apparently absent in the southeastern lowland sector.

Ranges from Michigan and Ontario to Manitoba, south to Tennessee, Arkansas, and Kansas.

The number of flowers per plant varies from one, described as var. *uniflorum* Farwell to several. Vigorous plants with more numerous leaves, 8–16 to a whorl, and with large and numerous flowers, have been described as *L. peramoenum* Farwell. In the present work I have considered such differences in numbers of flowers and leaves as varying responses to the amount of moisture in the soil as well as age and vigor of the individual plant, and as not meriting recognition.

The final taxonomic status of *Lilium michiganense*, the Turk's Cap Lily of Missouri, is still open to argument. Competent botanists have considered it as a distinct species (Mill, Deam, Wherry, Fernald), as the same as or synonymous with *Lilium superbum* L. (Gleason, Hull), and as a subspecies of *L. canadense* L. (Boivin and Cody). In general appearance of having

strongly recurved sepals and petals, *L. michiganense* appears more closely related to *L. superbum*, yet in various characters, such as the ribbing of the sepals and petals, shorter anthers, occurrence of tiny projections (spicules) on the leaf margins and veins of the lower leaf surface, circumneutral to subacid soil preference, time of flowering in early summer, the tendency toward an umbellate type of inflorescence, and the morphology of the karyotypes of the somatic chromosomes, *L. michiganense* is definitely more closely related to *L. canadense*.

Although *L. michiganense* may occasionally overlap into *L. superbum* in anther length, relative smoothness of leaf margin and veins on lower surface, ribbing of the sepals and petals, and type of inflorescence, yet in the main it shows fairly stable characters by which it can be recognized both in the field and herbarium, and is treated in the present work as a distinct species. For further details on arguments pro and con as regards *L. michiganense* the reader is referred to Rhodora 44: 220–27, 453–56. 1942; Rhodora 46: 86–87. 1944; Rhodora 58: 14–20. 1956; Amer. Jour. Bot. 34: 9–26. 1947; and Proc. Iowa Acad. Sci. 31: 265. 1926.

This species does well in cultivation and in wild-flower gardens in either sun or shade, and multiplies over the years.

The fleshy bulbs of this and other species of the genus were eaten by North American Indians. After being cooked, they possess a somewhat sweet flavor and starchy consistency.

2. *Lilium tigrinum* L. Tiger Lily

Map 628

Flowers July–September.

This is a well-known cultivated species, which rarely is found in Missouri as an escape from gardens. It is definitely known in Missouri to have become naturalized or adventive in St. Louis and Christian (2 mi. south-west of Billings, July 13, 1955, *Palmer 60565*) counties.

Native of eastern Asia; introduced into the United States, ranging there as an escaped plant from New England to North Dakota, south to Virginia and Missouri.

11. *Erythronium* L. Dog-tooth Violet

- a. Flowers yellow, either partly or entirely so; a glandular spot is present on each margin of the petals near the base; sepals and petals with strongly forking side (lateral) veins which arch toward the margins (seen best on dried specimens); stigmas erect, slightly if at all separated, usually shorter than 2 mm.; leaves usually conspicuously mottled brown and green on upper surface (but also unmottled), with a solid rich green color on lower surface without any silvery glaucous or pale brown-lavender color or mottling 1. *E. AMERICANUM*
- a. Flowers white, pinkish-white, lilac-white, or bluish-white with greenish and yellow at base; no glandular spot present on sepals or petals; sepals and petals without a rounded or subcordate base, the veins mainly parallel or only the outermost side ones slightly forking and arching (seen best on dried specimens); stigmas spreading and curving outward, separated, mostly 2–3 mm. long; leaves less mottled or not at all mottled on upper surface, the lower surface gray- or silvery-green (glaucous) with or without a pale brown-lavender color or mottled effect. b
- b. Plants growing chiefly in low or moist woods along streams, valleys, on slopes and wooded bluffs; sepals and petals usually recurved or conspicuously spreading, with chiefly white predominant, often tinged with pinkish, lavender, or bluish; leaf-blades 1.3–4 cm. broad, flat, elliptical-lanceolate to ovate-lanceolate, somewhat or more or less mottled on both surfaces; colonies of numerous sterile 1-leaved plants present and predominating, the flowering plants not numerous; bulbs sending out slender long runners with a new bulb forming at the tip of the runner . . . 2a. *E. ALBIDUM*
var. *ALBIDUM*
- b. Plants growing mostly on glades, prairies, or dry open woods; sepals and petals more ascending and remaining closer together or often only slightly spreading, not strongly recurved, with lavender or bluish-lilac predominating; leaf-blades mainly 0.5–2 cm. broad, slightly folded with margins upcurved, mostly linear-lanceolate to narrowly lanceolate, not mottled or very rarely mottled above, not mottled below; flowering plants generally more scattered but more numerous, the sterile 1-leaved types less numerous and appearing mostly later than the flowering individuals; bulbs generally without runners, a new bulb forming at the base of the old one. . . . 2b. *E. ALBIDUM*
var. *MESOCHOREUM*

1. *Erythronium americanum* Ker Yellow
Adder's Tongue, Yellow Dog-tooth Violet Map 629

Flowers late March–May.

Occurs in low rich woods along streams or low wooded slopes and along bluffs. Uncommon, mainly in southern Missouri, north in central Missouri to St. Louis, Franklin, and Boone counties.

Ranges from New Brunswick to Ontario and Minnesota, south to Florida, Alabama, Tennessee, Arkansas, and Oklahoma.

The plants occurring in Missouri belong to *E. americanum* f. *americanum* with the flowers mainly yellow. The leaves are usually mottled with rich brown, but unmottled leaves also occur. The three outer sepals are usually yellow within and yellow with pale brown down the center on the outside, less commonly are they greenish within, brownish at the tip, and greenish-brown on the outside, while the three inner petals are usually yellow and somewhat dull

orange mottled within toward the base, in age becoming more orange-brown. Flowers with a chestnut-brown color, known as f. *castaneum* L. B. Sm., have not been recorded from the state.

Large colonies are usually found consisting chiefly of 1-leaved sterile plants, the number of flowering plants with 2 leaves being comparatively small. About four years are required following seed germination to flower production. Also, bulbs from flowering plants which have been transplanted usually appear slow in recovering from the change in transplanting and may require more than a year before they again produce flowers. They do well in wildflower gardens in rich, loose, often sandy, shaded soils.

In early spring the leaves are sometimes used as a cooked vegetable, and the bulbs of this and other species of the genus are reputed to be edible either raw or cooked. The bulbs are also reported to have emetic properties.

2a. ***Erythronium albidum* Nutt. var. *albidum***

White Dog-tooth Violet. Also called White Trout Lily, White Fawn Lily, Map 630
White Adder's Tongue.

Erythronium albidum var. *coloratum* Sterns [Shinners]

Erythronium albidum Nutt. [G, P & S]

Flowers late March–May.

Occurs chiefly in low or moist woods, often alluvial soils, along streams, in valleys, on wooded slopes and bluffs. Common throughout Missouri and doubtless in every county.

Ranges from Ontario to Minnesota, south to Georgia, Kentucky, Arkansas, and Oklahoma.

This species reacts to transplanting similarly to *E. americanum*, the bulbs requiring a year or two to regain the setback temporarily caused by transplanting. Once established, however, they thrive in wildflower gardens.

Flowers vary in color from pinkish-white to bluish-white. *Erythronium albidum* var. *coloratum* Sterns (Bull. Torr. Club 15: 111. 1888) is described as a pink dog-tooth violet with the sepals white and 'more or less suffused with rose-purple, varying to bright red' and with the 'leaves more strongly mottled with green and brown than in the type.' Since the mottled leaves and habitat in 'shaded woods near streams' are more characteristic of typical var. *albidum* than of var. *mesochoreum*, the description would seem to apply more generally as a color variation of var. *albidum*, the interpretation regarded in the present flora, rather than as synonymous with var. *mesochoreum*, as interpreted by Shinners.

Sterile plants or colonies of individuals of *E. albidum* may be distinguished from similar plants of *E. americanum* by noting the lower surface of the living leaves, those of *E. americanum* being rich green without any trace of mottling, or of any glaucous-silvery color mixed with pale brown-lavender, whereas in *E. albidum* the lower surface is glaucous-silvery with a pale brown-lavender mottling showing.

2b. ***Erythronium albidum* var. *mesochoreum***

(Knerr) Rickett Prairie Dog-tooth Violet

Map 630

Erythronium mesochoreum Knerr [P & S]

Flowers late March–May.

Occurs in prairies, rocky glades, and open woods.

Ranges from Iowa and Nebraska, south to Missouri, Oklahoma, and Texas.

It is questionable whether this should be retained as a variety or as a species. Rickett (Rh. 39: 101–5. 1937) has produced evidence to show intergradation and overlapping of characters between *E. mesochoreum* and *E. albidum*. While such intergradation does occur and specimens are found which are difficult to place definitely, my own field experience has been that the majority of plants can be readily distinguished and separated in the living or growing condition. We may have here actually, instead of a variety, an example of an incipient or young species which has not become absolutely stabilized, with intermediate types occurring as hybrids or having hybrid origin where the ranges of the two taxa (categories) overlap. The same problem is encountered in various other members of the native flora. Only future detailed investigations of these two *Erythronium* will reveal a more definite answer as to how distinct they are.

In addition to the differences presented in the key, I have observed another one which should be subjected to future study and detailed observation. This apparent difference was noted in the fruiting stage of the plant, where it was found that in *E. albidum* var. *mesochoreum* the fruiting peduncle bends so strongly downward that it carries the fruiting capsule nearly or quite to the ground. In *E. albidum* var. *albidum*, on the other hand, the fruiting peduncle remains rather spreading or slightly drooping, but does not arch so strongly as in var. *mesochoreum*.

12. ***Camassia* Lindl. Wild Hyacinth**

Flowering early April–late May; flowers pale blue or pale lilac to whitish; inflorescence chiefly 7–50- (less frequently 50–85-) flowered, 4–18 (rarely to 32) cm. long; petals and sepals 10–15 mm. long, 3–4 mm. wide; style 4.5–7 mm. long, whitish to pale bluish; filaments 6–8 mm. long, pale lilac, pale blue to whitish; capsule nearly globose, as broad as or broader than long, 6–11 mm. long, 5–12 mm. wide; pedicels spreading-ascending or widely spreading in fruit, the capsules spreading away from main axis of inflorescence; stem with flowers or fruit mainly 3.2–5.5 (up to 7.5) dm. tall, the leaves 1/2 height or nearly equaling the height; bracts 0–2 on flower-stem (scape) below lowest flower-stalk, at most 8 cm. below the lowest flower-stalk, straight or slightly curved after flowering; petals and sepals spreading after flowering, their upper portions not joining after flowering 1. *C. SCILLOIDES*
Flowering early May–late June; flowers lavender to pale purple; inflorescence chiefly 50–100-flowered (where flowers have disappeared, the flower-stalks remaining in place indicate location of flower), 15–40 cm. long; petals and sepals 7–9 mm. long, 1.5–3 mm. wide; style 3.5–4 mm. long, lavender;

632 *Camassia angusta*

Occurs in prairies and rocky open ground in Monroe (*Steyermark 85377*), Shelby (*Steyermark 64553*), Randolph (*Naylor and McVeigh*), Polk (*Palmer 62666* and *62725*), St. Clair (*Steyermark 83080*), and Jasper (*Palmer 25278*) counties.

633 *Scilla sibirica* (Squill)634 *Ornithogalum umbellatum* (Star-of-Bethlehem)635 *Ornithogalum nutans* (Star-of-Bethlehem)

Ranges from Illinois (Mason Co.) to Missouri, south to Kansas, Oklahoma, and Texas.

Gould in his treatment of *Camassia* (Am. Midl. Nat. 28: 712-42. 1942) considered *C. angusta* as possibly a distinct subspecies of *C. scilloides*. Basing his opinion on slender, small-flowered plants of Kansas, Oklahoma, and Texas, he remarks, 'These plants generally have small flowers whose perianth segments spread for a short time and then are connivent over the ovary. In most cases, fertilization apparently is not accomplished, and the flowers are deciduous without further development of the ovary.' In the Illinois and Missouri material, however, while many flowers are deciduous, many others are fertilized and develop mature fruit.

I have been familiar with this plant in the field since 1947, when Mr. Bill Bauer of Kimmswick, Missouri, first called it to my attention, and have had plants growing under observation in my wildflower garden which were transplanted from Missouri and also sent to me from Illinois by Mr. Virginus Chase.

Study and observation of these plants for more than ten years in the field and herbarium have convinced me that they are specifically distinct from the common earlier-blooming *C. scilloides*, as indicated by the main differences given in the key.

Besides the much later blooming period, this species differs in the more robust, taller plants, with a much longer raceme of more numerous flowers of a lavender to purple instead of pale bluish to whitish color, smaller sepals and petals, shorter lavender to purple styles and filaments, 7-21 conspicuous bracts occurring on the main scape 17-40 cm. below the base of the inflorescence and lowest pedicels, more erect-ascending fruiting pedicels with the longer than broad fruiting capsules more closely appressed to the main axis of the inflorescence, proportionately shorter leaves as compared with the height of the flowering stem, and more rounded, globose bulbs. Plants of *C. angusta* start flowering at a time when most of the plants of *C. scilloides* have finished flowering and already have begun to form fruits. This is true even in the same general latitude or locality where the two may be present. The incurving-erect fruiting pedicels with the capsules nearly appressed to the axis of this species are similar in that respect to those of the western *C. Quamash*. The latter species differs from *C. angusta* in its longer (12-35 mm.) and broader (2-8 mm.) sepals and petals, in the sepals and petals always converging together over the capsule and persisting on it after flowering has occurred, in the relatively smaller number of flowers to the inflorescence, and longer capsules.

13. *Scilla* L. Squill

***Scilla sibirica* Andr.** Squill
Flowers in March and April.

Map 633

Cultivated in gardens and rarely escaped to roadsides, vacant grassy areas, and waste places in Pike and Boone counties.

Native of Eurasia.

The plant from Pike County was previously referred erroneously by Palmer and Steyermark (*Annot. Cat. Fl. Pl.* p. 502. 1935) to *Scilla biflora* L. (= *S. bifolia* L.), a species as yet not known as naturalized in the state. This error was later corrected in Steyermark's *Spring Flora of Missouri* (p. 72).

Plate no. 115. 1. *Ornithogalum umbellatum*, $\times \frac{2}{7}$. 2. *Erythronium americanum*, $\times \frac{2}{7}$. 3. *Scilla sibirica*, $\times \frac{2}{7}$. 4. *Camassia scilloides*; a. *Camassia scilloides* f. *scilloides*, $\times \frac{2}{7}$; b. *Camassia scilloides* f. *Petersenii*; Leaf, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 5. *Yucca Smalliana*; a. PLATE NO. 115

- a. Flowering or fruiting axis simple and unbranched, or with a few short branches at the base of the axis, the inflorescence a raceme-like panicle; leaves longer than the lower part of the flowering or fruiting portion; main leaves mostly 0.4–2.5 cm. broad b
- b. Plants of the loess hills of northwestern Missouri; leaves stiff and rigid, 0.4–1.2 cm. broad; seeds 10–13 mm. long; petals and sepals short-pointed (acute). 2a. *Y. GLAUCA* var. *GLAUCA*
- b. Plants of the southernmost Ozark counties; leaves rather soft and flexible, mostly 1–2.5 cm. broad; seeds 8–10 mm. long; petals and sepals mostly blunt (obtuse) at tip 2b. *Y. GLAUCA* var. *MOLLIS*

1. ***Yucca Smalliana*** Fern. Spanish Bayonet,
Adam's Needle Map 637
Yucca filamentosa [of BB, P & S and most authors],
not L.
Flowers May–August.

Commonly cultivated in gardens, and occasionally escaped and established away from cultivation in thickets, along roadsides, open banks, railroads, and open woods. Scattered in Missouri.

Native of the United States from Florida to Louisiana, north to North Carolina and Tennessee.

According to Fernald (Rh. 46: 5–9. 1944), the *Yucca* which Linnaeus described as *Y. filamentosa* is a plant of the coastal plain ranging from Georgia to New Jersey.

The fleshy succulent flowers of this and the other species of *Yucca* may be used fresh in salads in combination with other vegetables, or may be cooked as a vegetable, dipped in eggs and fried, or mixed with meats, as is usually done with those of *Y. elephantipes* Regel, a species of Central America and Mexico.

The flattened black seeds packed closely together in vertical tiers resemble those of the Dutchman's Pipe Vine (*Aristolochia tomentosa*).

- 2a. ***Yucca glauca*** Nutt. var. ***glauca*** Soapweed Map 638
Yucca angustifolia Pursh [Shinners]
Flowers May–July.

Occurs only on open, dry exposed slopes of loess hills in Holt and Atchison counties, northwestern Missouri.

Ranges from Iowa and North Dakota to Montana, south to northwestern Missouri, Texas, New Mexico, and Arizona.

The roots of this species contain a soapy substance, which may be employed as a soap substitute. The leaves are sometimes made into stable brooms.

Some of the Indians of the western United States eat the fresh fruiting capsules or the dried roasted ones, ground into meal. A fermented beverage is reported to be made by them from the fruits.

- 2b. ***Yucca glauca*** var. ***mollis*** Engelm. Map 638
Yucca arkansana Trel. [BB, P & S]
Flowers May–June.

Occurs on rocky wooded slopes and banks along streams in limestone soils, and infrequently on dry rocky limestone glades. Known only from the southernmost counties bordering Arkansas, from Oregon County on the east to Barry County on the west.

Ranges from southern Missouri and Oklahoma to Arkansas and Texas.

The flowers are greenish-white in general, but the sepals show a tinge of purplish-pink over their whole surface with a broad greenish-white margin. The petals are somewhat longer and broader than the sepals.

17. ***Asparagus*** L. *Asparagus*

- Asparagus officinalis*** L. *Asparagus* Map 639
Flowers May–June.

Commonly cultivated and often escaped along railroad tracks, roadsides, fields, thickets, and waste ground.

Native of Europe; introduced into the United States and Canada where naturalized throughout the United States north to Quebec and Ontario.

The small greenish-yellow flowers on slender stalks along the branches are followed in late summer and fall by scarlet or orange-red globular berries containing

a few rounded seeds. The small brownish scales on the stem are the true leaves, whereas the fine, green, threadlike, leafy-appearing clusters in the axils of the scales are actually divisions of branchlets which function as leaves, but instead have the structure of a stem or branch.

Wild escaped plants are less tender than the cultivated, but, nevertheless, when gathered as young sprouts just out of the ground, make a suitable morsel for a meal.

639 *Asparagus officinalis* (Asparagus)640 • *Smilacina racemosa* var. *racemosa* (False Solomon's Seal)
640 x *Smilacina racemosa* var. *cylindrata* (False Solomon's Seal)641 *Smilacina stellata* var. *stellata* (Starry False Solomon's Seal)18. *Smilacina* Desf. False Solomon's Seal

Flowers numerous, 40 or more on short pedicels (the individual flower-stalks), in a branched panicle; mature berries red, numerous; leaves with 3 or 5 conspicuous ribs on both lower and upper surface and dark or grass-green, not covered with a pale or gray-bluish (glaucous) coating; sepals and petals 1.5-3 mm. long 1. *S. RACEMOSA*

Flowers few, less than 15, on long pedicels about 4-6 mm. long, in a simple unbranched raceme; mature berries green or black with black stripes; leaves with less conspicuous ribs on both surfaces and with a pale or gray-bluish (glaucous) coating; sepals and petals 4-6 mm. long 2. *S. STELLATA*

1. ***Smilacina racemosa* (L.) Desf. False Solomon's Seal, False Spikenard** Map 640
Flowers May-June.

Occurs in rich nonrocky or rocky woodland. Throughout Missouri.

As treated by Fernald, Missouri material has been divided into the following two variations:

Inflorescence ovoid to pyramidal, 3-10 cm. in diameter, 7-17 cm. long, 3/8-3/4 as broad as long, its longer branches 2-6 cm. long and with 8-24 flowers; peduncle (main supporting stem of inflorescence) usually less than half the length of the inflorescence; larger leaf-blades 3.5-9.5 cm. broad, 10-25 cm. long; main stem 5-10 dm. high . . .

1a. *S. RACEMOSA* var. *RACEMOSA*

Inflorescence nearly cylindrical, 1.5-3 cm. in diameter, 4.5-8.5 cm. (rarely to 13 cm.) long, 1/4-3/8 as broad as long, its longer branches 1-2.5 cm. long and with 6-10 flowers; peduncle half as long as or longer than the length of the inflorescence; larger leaf-blades 3.5-6 cm. broad, 8.5-17 cm. long; main stem shorter, at most up to 7.5 dm. high . . . 1b. *S. RACEMOSA* var. *CYLINDRATA*

Scattered throughout Missouri.

Ranges from Quebec to British Columbia, south to Virginia, North Carolina, Tennessee, and Missouri.

- 1b. ***Smilacina racemosa* var. *cylindrata* Fern.**

Map 640

Scattered over the state, somewhat more common.

Ranges from Georgia to Arizona, north to New Hampshire, New York, Ontario, Ohio, Michigan, Wisconsin, Kansas, and Colorado.

These two variations need to be studied more carefully throughout their ranges before any final statement can be made as to their relative merit. Until those studies are forthcoming, the varieties are being maintained in all fairness to Fernald's observations.

The cooked young shoots are used as a substitute for asparagus, and the starchy rootstocks were eaten, after having been soaked first in lye and then parboiled like potatoes, by some Indian tribes. The fresh berries have a flavor said to suggest that of bitter molasses, but possess a cathartic action.

642 *Polygonatum biflorum* f. *biflorum* (Solomon's Seal)643 *Polygonatum canaliculatum* (Solomon's Seal)644 *Medeola virginiana* (Indian Cucumber-root)

Flowers May–June.

Occurs on wooded alluvial banks and on rich wooded slopes, mostly in alluvial low valleys along streams of northern and central Missouri south to Warren, Boone, and Jackson counties, and locally south in the Ozarks in Shannon County along Jack's Fork of Current River in the vicinity of Jam-up Bluff.

Ranges from Newfoundland to British Columbia,

south to Virginia, Ohio, Indiana, Illinois, Missouri, Kansas, New Mexico, Arizona, and California. A var. *crassa* Vict. is distributed from Labrador to Maine and Connecticut.

Before reaching the flowering stage, the young stems and leaves may be picked and cooked as 'green.'

19. *Polygonatum* Mill. Solomon's Seal

Flowers usually 1–3 (rarely to 5) hanging from each peduncle (main stalk supporting inflorescence); peduncles terete (round in cross-section) or nearly so; perianth of flower 10–17 mm. long, the lobes 3–4 mm. long; topmost small leaf-blade with 20–66 nerves; leaf-blades sessile (without a stalk) or nearly so, the main nerves 1–5 (up to 9) and becoming faint or lost below the tip; stem 2–9 dm. high, slender

1. *P. BIFLORUM*

Flowers usually 2–10 hanging from each peduncle; peduncles flattened; perianth of flower 17–22 mm. long, the lobes 5–6.5 mm. long; topmost small leaf-blade with 58–112 nerves; leaf-blades narrowed to a somewhat stalked base, the main nerves 7–19 and mostly conspicuous to the tip; stem 6–20 dm. tall

2. *P. CANALICULATUM*

1. *Polygonatum biflorum* (Walt.) Ell. f. *biflorum* Solomon's Seal Map 642

Polygonatum canaliculatum in part [of P & S], not (Muhl.) Pursh

Polygonatum biflorum (Walt.) Ell. [G, BB]

Flowers May–June.

Occurs in rich low woods and wooded slopes. Throughout Missouri.

Ranges from Florida to Texas, north to Connecticut, New York, Ontario, Michigan, Illinois, Iowa, and Nebraska.

For relative merit of this species, see discussion under *P. canaliculatum*.

2. *Polygonatum canaliculatum* (Muhl.) Pursh Map 643

Polygonatum canaliculatum var. *ovatum* (Farwell)

Palmer & Steyererm. [P & S]

Flowers May–June.

Occurs in rich or rocky woods, alluvial thickets and stream banks, along railroads, and open places. Throughout Missouri, and more common than the preceding species.

Ranges from New Hampshire to Manitoba, south to South Carolina, Tennessee, Missouri, and Oklahoma.

The young leafy shoots may be cooked and eaten as a substitute for asparagus, while the dried root-stocks are reputed to be used as a bread. The root-stocks resemble those of the poisonous May-apple (*Podophyllum peltatum*), but have large circular scars, whereas these circular scars are absent in May-apple.

Polygonatum canaliculatum and *P. biflorum*, while apparently often recognizable as distinct, are frequently difficult to separate from one another because of overlapping and intergrading characters. Plants occur combining 1–3-flowered peduncles with a longer perianth and leaves characteristic of *P. canaliculatum*,

or combining short-perianth forms with leaves and other characters of *P. canaliculatum*, as well as other types of noncorrelation of characters. Therefore, there is considerable doubt in the author's mind as to whether these two *Polygonatum*s can be maintained as separate species. They may be no more than ecological variations or even growth forms of the same

species with at most recognition in the category of variety or form.

Although the group has been monographed by several students, there is much need for more detailed field and breeding investigations of the species in this genus, especially in the *P. canaliculatum-biflorum* complex.

20. *Medeola* L. Indian Cucumber-root

Medeola virginiana L.

Map 644

Flowers May-June.

Known from a collection from Linn County, northern Missouri (near bank of stream, May 22, 1860, *Broadhead* in University of Missouri herbarium).

Ranges from Quebec, Ontario, and Minnesota, south to Florida, Alabama, and Louisiana.

Numerous localities have been searched for in likely looking spots in Linn County and other northern Missouri counties in an effort to relocate this species which *Broadhead* presumably collected in

1860. It is to be hoped that it will eventually be found at some place in the state. The small 3-9 flowers have greenish-yellow, recurved perianth-segments, protruding above the upper tier of 3-5 ovate leaves. The fleshy globose berries turn dark purple, and in the fall the leaves become flushed with purple.

The whorled leaves resemble somewhat those of the orchid, *Isotria verticillata*.

The succulent thickened rootstock may be eaten raw, resembling somewhat the taste of cucumber, or used in salad form with vinegar and dressing.

21. *Trillium* L. Trillium, Wake Robin

- a. Flower sessile (arising directly from top of stem and leaf clusters) *b*
- b. Mature leaves narrowed to a petiole (leaf-stalk); sepals turned down (reflexed); petals abruptly narrowed at base into a distinct claw 3. *T. RECURVATUM*
- b. Mature leaves sessile, without a petiole; sepals spreading to ascending; petals without a claw or narrowed to a claw-like base *c*
- c. Stamens about $\frac{1}{2}$ - $\frac{5}{8}$ length of petals; petals 15-36 mm. long, 2.8-5 times longer than broad, broadest in the lower half or near the middle, narrowly to broadly elliptical, without a claw-like base, the narrowed base at most 2 mm. long; connective of the anther prolonged to a broadly triangular-lanceolate tip, somewhat pointed, flattened, 2-3.5 mm. long 1. *T. SESSILE*
- c. Stamens mostly between $\frac{1}{4}$ - $\frac{1}{2}$ (infrequently $\frac{3}{8}$) length of petals; petals 36-75 mm. long, 5-8 times longer than broad, broadest in the upper half, oblanceolate to linear-oblanceolate to nearly linear, conspicuously narrowed in the lower one-third to one-fifth to a claw-like base 7-15 mm. long; connective of the anther prolonged into a rounded thick tip mostly 0.5-1.5 mm. long 2. *T. VIRIDE*
- a. Flower on a peduncle (stalk) which connects the flower to the top of the stem *d*
- d. Leaves very large, 7-20 cm. broad, 7-20 cm. long, broadly rhombic (shaped roughly like a baseball diamond), abruptly long-pointed (acuminate) at tip; peduncle (flower-stalk) 3-12 cm. long, usually spreading horizontally or turned down while in full flower; main part of style lacking or not evident; ovary and fruit with 6 sharp angles 4. *T. FLEXIPES*
- d. Leaves small or medium-sized, 1-3 cm. broad, 1.5-8.5 cm. long, oblong to oblong-lanceolate to ovate, blunt (obtuse) at tip; peduncle (flower-stalk) 1-3 cm. long, erect and standing above the leaves while in full flower (in *T. nivale* turning down in fruit); main part of style 2 mm. or more long, evident; ovary and fruit with 3 rounded angles *e*
- e. Mature leaves narrowed to a definite petiole (leaf-stalk); stems mostly 3-10 cm. (rarely 15) tall; peduncle turned down and recurved in fruit; petals white at all stages; plants mainly of alkaline soils of north-facing limestone slopes mainly north of the Missouri River 5. *T. NIVALE*
- e. Mature leaves without a petiole (leaf-stalk); stems mostly 10-30 cm. tall; peduncle remaining erect in fruit; petals partially or entirely pink or rose, at least on outer or lower surface, white elsewhere; plants of acid soils of upland oak-hickory or pine woods in shallow draws. 6. *T. PUSILLUM*
var. *OZARKANUM*

645 • *Trillium sessile* f. *sessile* (Wake Robin)645 □ *Trillium sessile* f. *viridiflorum* (Wake Robin)646 *Trillium viride* var. *viride* (Green Trillium)647 • *Trillium recurvatum* f. *recurvatum* (Purple Trillium)647 □ *Trillium recurvatum* f. *Shay*647 † *Trillium recurvatum* f. *petaloideum*647 x *Trillium recurvatum* f. *foliosum*

1. ***Trillium sessile* L.** Wake Robin Map 645
Flowers early April–early June.

Occurs in either low rich bottom woods of valleys or on wooded slopes, in rocky or nonrocky soils.

Ranges from Georgia to Arkansas, north to New York, Pennsylvania, Ohio, Indiana, Illinois, and Missouri.

Missouri material may be divided into the following two variations:

Petals brown-purple, maroon, or brick-colored throughout or mixed with dull green . 1a. *T. SESSILE* f. *SESSILE*

Petals mainly greenish-yellow, brownish-yellow, yellow, or greenish . 1b. *T. SESSILE* f. *VIRIDIFLORUM*

1a. ***Trillium sessile* L. f. *sessile*** Map 645
Trillium sessile L. [G, BB, P & S]

Common throughout southern and central Missouri, and ranging northward to Marion, Monroe, Randolph, Linn, Ray, and Jackson counties; absent from the lowland counties of southeastern Missouri. The commoner of the two color variations in the state. The anthers and filaments are usually maroon or purplish-brown in this form.

1b. ***Trillium sessile* f. *viridiflorum*** Beyer Map 645

Trillium sessile f. *luteum* (Muhl.) Peattie [P & S, Deam], not *T. luteum* (Muhl.) Harbison, nor *T. sessile* var. *luteum* Muhl.

Scattered in the range of f. *sessile* and often occurring with it. The anthers of this form are usually green and the filaments yellow.

Trillium sessile is the commonest species of the genus

in the state. Some of the standard manuals disagree on the matter of mottling of the leaves in *T. sessile*. Actually, both mottled and unmottled leaves are found over the range in the state, with unmottled-leaved individuals more common.

The relatively shorter petals broadest in the lower half with a very short narrowed base and the stamens about one-half the length of the petals will distinguish this species and its forms from the next one, *T. viride*.

The unfolding leaves of young plants of this and other species of the genus may be cooked as a green vegetable. The roots are reported to be emetic.

2. ***Trillium viride* Beck var. *viride*** Map 646
Green Trillium

Trillium viride Beck [G, P & S]

Trillium viridescens Nutt. [P & S]

Trillium luteum [of G in part], not (Muhl.) Harbison

Trillium sessile var. *Nuttallii* Watson

Flowers April–May.

Occurs in rich soils of valleys along streams, and on rich or rocky wooded slopes, generally in limestone areas. Found in two areas, (1) extreme southwestern Missouri along the White River and tributaries, and (2) eastern Missouri from Bollinger and Reynolds counties to Ralls and Audrain counties.

Ranges from southern Illinois, Missouri, and eastern Kansas, south to northern Arkansas and eastern Oklahoma.

This species may be readily distinguished from *T. sessile* on the basis of the characters presented in the key. While there is variation in the shape, size, and coloring of the petals and in the amount of tapering of the leaf-tip, prolonged field study and growing of

PLATE NO. 117

T. viride var. *viride* has convinced the author of its distinctness from *T. sessile*. The usual coloring of the petals is greenish or greenish-yellow to yellow over the main portion with maroon, purple, or purplish-red in the narrowed clawlike base or lower part. Rarely are found plants (Steyermark 84448 from Lincoln County) in which the petals are dull maroon throughout. The petals vary from usually oblanceolate to almost linear and taper to a narrow clawlike base 2–5 mm. wide; sometimes the base is not so distinctly narrowed. The filament and connective are usually dark maroon or purple, and the anthers range from yellow to purplish.

Study of *T. viridescens* in the field and herbarium shows that it cannot be separated even as a form or variety from *T. viride* var. *viride*. While *T. viridescens* has sharp-pointed (acuminate) leaves, and *T. viride* var. *viride* has them mostly short-pointed (acute), yet plants of *T. viride* often vary within a given locality from acute to acuminate, and cannot be distinguished from equally acuminate leaf tips of *T. viridescens*.

As regards the matter of hairs in *T. viride* var. *viride* being present at the summit of the stem and at the base of the main nerves of the lower side of the leaves, this character has been found after extensive field and herbarium studies to be unsuitable for differentiating *T. viride* var. *viride* from *T. sessile* for the following reasons: (1) these hairlike excrescences are often not too evident or well-developed, and (2) close examination of typical plants of *T. sessile* reveals similar, although on the average shorter, excrescences. Sometimes the hairlike projections on *T. viride* var. *viride* are well-developed and conspicuous, but this is by no means a typical condition to be relied upon.

Gleason (*New Ill. Fl.* 1: 432. 1952) has given the most realistic presentation of the close relationship of *T. viride* var. *viride* with *T. luteum* (Muhl.) Harbison and *T. Hugerii* Small [= *T. cuneatum* Raf.] by treating these last taxa as one variety, var. *luteum* (Muhl.) Gl. For a number of years I have had growing in my wild-flower garden plants of *T. luteum* (Muhl.) Harbison [= *viride* var. *luteum*] from eastern Tennessee. The petals, which are greenish-yellow to yellow throughout, lack the maroon or purple base of *T. viride* var. *viride* and are broader and less contracted in the lower half than var. *viride*. The leaves of *T. viride* var. *luteum* with their stronger mottling of pale green and gray-white are in contrast to a duller and darker type of mottling in var. *viride*. The summit of the stem and the nerves of the lower leaf surface are practically glabrous in *T. viride* var. *luteum*, but there are intergrading forms which show some hairlike projections. For plants in Missouri referred by Gray's *Manual* to *T. luteum*, see

under excluded species following treatment of this genus.

3. *Trillium recurvatum* Beck Purple Trillium

Map 647

Also called Bloody Butcher and Purple Wake Robin. Flowers early April–May.

Occurs usually in rich woods in alluvial soils of valleys and along streams, and at the base of wooded slopes and rocky bluffs, occasionally in open low grassy areas bordering fields and roadsides. Most common in eastern Missouri, with scattered stations westward in central Missouri to Saline and Clay counties, and in the southernmost counties bordering the Arkansas line west to Stone County.

Ranges from Ohio, Michigan, Minnesota, and Iowa, south to Alabama, Mississippi, and Arkansas.

Missouri material is represented by the following variations:

- a. In addition to the 3 normal leaves, the sepals, petals, stamens, and carpels are changed to green leaf-like parts. . . . 3d. *T. RECURVATUM* f. *FOLIOSUM*
- a. Plants with normal leaves and with colored sepals, petals, stamens, and carpels b
- b. Petals yellow or yellow-green; stamens yellow or yellow-green . . . 3b. *T. RECURVATUM* f. *SHAYI*
- b. Petals maroon, purplish, or red-brown; stamens dark purple or maroon c
- c. The 3 sepals green with or without purple edging, thicker than the petals . . . 3a. *T. RECURVATUM* f. *RECURVATUM*
- c. The 3 sepals maroon or purplish, about as thin as the petals . . . 3c. *T. RECURVATUM* f. *PETALOIDEUM*

3a. *Trillium recurvatum* Beck f. *recurvatum*

Map 647

Trillium recurvatum Beck [G, BB, P & S]

The common form encountered in the state.

3b. *Trillium recurvatum* f. *Shayi*

Palmer and Steyermark.

Map 647

Known in Missouri only from St. Louis (Monarch Hill, near Monarch, April 29, 1935, *W. F. Shay*, type collection in Missouri Botanical Garden Herbarium), St. Charles (Weldon Springs, August Busch Wildlife area, spring, 1957, *Bruce Dowling* in University of Missouri herbarium), and Scott counties.

Recently recorded from southern Illinois.

A very handsome form which should be more widely grown.

648 *Trillium flexipes* f. *flexipes* (White Trillium)649 *Trillium nivale* (Snow Trillium)650 *Trillium pusillum* var. *ozarkanum* (Ozark Trillium)3c. *Trillium recurvatum* f. *petaloideum*

Steyserm.

Map 647

Known only from Cape Girardeau County (Houck Woods, Bloomfield Road, April 6, 1949, *Wayne Adams*, type collection in Southeast Missouri State College herbarium).

3d. *Trillium recurvatum* f. *foliosum* Steyserm.

Map 647

Known only from Cape Girardeau County (Houck Woods, Bloomfield Road, April 6, 1949, *Wayne Adams*, type collection in Southeast Missouri State College herbarium).

When the leaves of *Trillium recurvatum* are first unfolding, the narrowed petiolar base of the leaf-blade is not evident. However, fully grown leaves show a definite petiole.

4. *Trillium flexipes* Raf. f. *flexipes* White*Trillium*, White Wake Robin

Map 648

Trillium flexipes Raf. [G]*Trillium Gleasoni* Fern. [BB, P & S]

Flowers April-late May.

Occurs usually in rich woods on slopes or bluffs or in valleys of ravines, and along streams. Eastern Missouri north from Stoddard County to Ralls County, west to Wayne, St. Francois, Franklin, Cole, and Boone counties; absent from most of the Ozark and southeastern lowland sections.

Ranges from Michigan to Minnesota, south to Ohio, Kentucky, Tennessee, and Missouri; also in New York and Maryland.

This is the tallest of the species of *Trillium* in Missouri. The showy white petals occur at the tip of the usually horizontally spreading or reflexed peduncle. Occasionally the peduncle is nearly upwardly ascending. The fruit, when mature, is a rose-red color during summer. A form, f. *Walpolei* (Farw.) Fern., with maroon or purple petals, filaments, and ovary is known, but has not been recorded for Missouri.

5. *Trillium nivale* Riddell Snow Trillium

Map 649

Flowers from about March 12-April 16.

Occurs usually on limestone or cherty limestone soils of steep eroded forested slopes bordering streams, mostly in forests of Sugar Maple associated with White Oak and Northern Red Oak. Found mainly in north-eastern and east-central Missouri from Lincoln and Callaway counties north to Clark County, locally west in northwestern Missouri to Daviess County (Steysermark 84807) and locally south along Jack's Fork of Current River in Texas County.

Ranges from Pennsylvania to Minnesota, south to Kentucky and Missouri.

Upon drying in a plant press the leaves and petals shrink considerably.

This is the smallest species of *Trillium* in the state. Where it is found, it usually occurs in abundance, with hundreds or thousands of individual plants.

During the middle of March, when it starts flowering, only a few other plants, such as *Hepatica nobilis* var. *acuta* (*acutiloba*), *H. nobilis* var. *obtusata* (*americana*), and *Erigenia bulbosa*, are in bloom, so that the large white petals stand out conspicuously against the dark earth background. Slightly later, *Dicentra Cucullaria*, *Sanguinaria canadensis*, *Isopyrum biternatum*, *Erythronium albidum*, *Dentaria laciniata*, and *Lindera Benzoin* are in bloom with the *Trillium*. On slopes where the soil is not bare or is grown over by other vegetation, this *Trillium* is absent, apparently favoring the more eroded places where the soil is more exposed and has scattered limestone fragments visible.

It transplants easily and does well in a wildflower garden if provided with some shade and a limey soil with good drainage. It increases from year to year by seed or by underground shoots from the short rhizome.

By late July or early August the plants above ground shrivel and disappear.

6. **Trillium pusillum** Michx. var. **ozarkanum**
(Palmer & Steyererm.) Steyererm. Ozark Wake Robin
Map 650

Trillium ozarkanum Palmer & Steyererm. [P & S]
Trillium pusillum [of G and BB in part], not Michx.
Flowers April 13–early May.

Occurs in acid soils of shallow draws in thin cherty-flinty soils of oak-hickory, oak-pine, or oak-chestnut woodland in the southern Missouri Ozarks, where known from Shannon (west side of highway 80, T27N, R5W, sect. 34, 2 mi. south of Birch Tree, May 3, 1947, *Steyermark* 64262; same locality, 1946, *Bill Bauer*), Lawrence (*Palmer*), and Barry (3 mi. south of Cassville along highway 112 along road to Roaring River State Park, April 20, 1935, *Steyermark* 18628, type collection in Missouri Botanical Garden Herbarium; same locality, April 13, 1930, *Cora Shoop*) counties.

Known only from southern Missouri and northwestern Arkansas.

The leaves are membranaceous and soft in texture, and dull grass green on both sides. The petals assume a flat-horizontal, spreading, or arched-recurving position, but do not become erect or ascending. They vary in color from pure white within or tinged with varying amounts of pink or are deep madder- or rose-purple; on the lower or outer side they are usually tinged with varying amounts of rose-purple or pink. Usually it was noted in the field that the petals which had the deepest dark-purple-rose color were the narrowest ones of all.

Transplanted specimens from Missouri to the author's wildflower garden have grown and increased over a period of twelve years. The upper surface of the petals is white and the lower surface is pinkish; in age the lower surface turns a deeper pink, but the petals as a whole remain a more subdued or paler shade of pale rose or pink and have not attained the deeper richer

colors seen in the southern Missouri Ozarks.

The flowers have a fragrance somewhat resembling that of the Dandelion (*Taraxacum*).

Typical *T. pusillum* var. *pusillum* occurs in South Carolina and var. *virginianum* in Virginia. The var. *ozarkanum* differs from these in its longer peduncles, more strongly nerved, normally 5- instead of 3-nerved leaves and sepals, averaging broader, and petals averaging longer and broader. The Ozark variety inhabits dryish woodland, the other varieties a damp woodland.

Excluded Species

Trillium viride var. **luteum** (Muhl.) Gl.

Trillium luteum (Muhl.) Harbison [G]

Fernald in the eighth edition of *Gray's Manual* (p. 445) credits Missouri in the range of *T. luteum*. Missouri specimens placed in the *T. luteum* folder at Gray Herbarium were originally identified by W. A. Anderson in 1931 as *T. Hugerii* Small, as *T. Underwoodii* Small, by Fernald in 1943 as *T. cuneatum* Raf., and by S. J. Smith in 1943 as *T. viride* Beck. I agree with Dr. Smith's identifications. Apparently, specimens which appeared glabrous at the summit of the stem and on the nerves of the lower side of the leaves were identified by Anderson and Fernald as identical with specimens from the more eastern states. Since there appears to be no difference between such specimens and others which I have placed in *T. viride* var. *viride*, the Gray Herbarium material from Missouri should be referred to var. *viride*, whereas the material from the eastern and southeastern states may be identified as *T. viride* var. *luteum*, *T. cuneatum*, and *T. Hugerii*. For further discussion on the variability in *T. viride* var. *viride* and the weakness of the pubescence character previously relied on, the reader is referred to the author's discussion under *T. viride* var. *viride*.

22. **Smilax** L. Cathbrier, Greenbrier

- a. No part of the stem with prickles or thorns; low or climbing soft-stemmed herbaceous plants, dying back to the ground each year, and no part of the plant woody *b*
- b. Plant mostly erect, mainly 1.5–6 dm. tall (rarely up to 10 dm.), not climbing, without tendrils or with only weak tendrils in the upper part of stem; some or all of the peduncles (main flower-bearing stalks) arising from the axils of the bracts on the lower part of the stem below the lowest leaf 3. *S. ECIRRHATA*
- b. Plant eventually climbing by tendrils from the axils of most of the middle and upper leaves; peduncles arising from the axils of the normally developed leaves *c*

Plate no. 118. 1. *Trillium nivale*, $\times \frac{2}{7}$; a. Fruiting plant, $\times \frac{2}{7}$. 2. *Trillium pusillum* var. *ozarkanum*, $\times \frac{2}{7}$. 3. *Smilax herbacea* var. *herbacea*, $\times \frac{2}{7}$. 4. *Smilax glauca*; a. *Smilax glauca*; b. *Smilax glauca*. 5. *Smilax ecirrhata*, $\times \frac{2}{7}$; a. Staminate flower, $\times 1\frac{1}{7}$.

PLATE NO. 118

651 *Smilax pulverulenta* (Carrion-flower)652 • *Smilax herbacea* var. *herbacea* (Carrion-flower)
652 □ *Smilax herbacea* var. *lasioneura* (Carrion-flower)653 *Smilax ecirrhata* (Carrion-flower)

- c. Lower surface of leaf rich grass green like the upper surface, both surfaces glossy; leaf-blades thin and membranaceous, ending in a long-pointed (acuminate) tip, the margins minutely irregularly toothed and with projecting small hairs; inflorescence containing 10–35 flowers; fruit black 1. *S. PULVERULENTA*
- c. Lower surface of leaf paler than upper surface, and mostly gray-green or pale green, neither surface glossy; leaf-blades mostly obtuse (blunt) or acute (short-pointed), less frequently shortly acuminate, the margins usually not irregularly toothed nor with projecting hairs; inflorescence containing 20–100 or more flowers; fruit bluish-gray or covered with a bloom which can be rubbed off d
- d. Lower surface of leaves glabrous (without hairs); bracts on the stem below the regular leaves usually appressed (fitting close to the stem) 2a. *S. HERBACEA* var. *HERBACEA*
- d. Lower surface of leaves more or less hairy with rather short or minute hairs; bracts on the stem below the regular leaves usually loose or spreading 2b. *S. HERBACEA* var. *LASIONEURA*
- a. Some part of the stem, but usually the lowest part, bearing prickles or thorns; climbing plants with stem woody at least toward the base, tough otherwise and not dying back to the ground e
- e. Lower surface of leaves whitened, bluish-gray, or silvery 4. *S. GLAUCA*
- e. Lower surface of leaves about the same green color as the upper surface f
- f. Leaf-margin much more thickened than rest of leaf-blade; at least the older stems more or less stellate-pubescent (with tufts of small star-shaped clustered hairs); tooth-like projections and irregularities of leaf-margins, when present, colored; leaves sometimes fiddle-shaped (panduriform), otherwise ovate; veins and veinlets thickened and conspicuous in a network over the leaf surface 6. *S. BONA-NOX*
- f. Leaf-margin not thicker than rest of leaf-blade; stem glabrous throughout; tooth-like projections and prickles of leaf-margins colorless; leaves never fiddle-shaped; veins and veinlets slender forming a delicate network which is not thickened conspicuously g
- g. Plants found only in southeastern Missouri; prickles of stem pale or with a dark tip, flattened and with a broad base; peduncle (main stem bearing the flowering or fruiting cluster) 3–15 mm. long, mostly shorter than or about equaling the leaf-stalk (petiole) of the leaf from whose axil it appears; fruit blue-black, covered with a grayish-blue coating (glaucous); seeds 2–3 in each berry 7. *S. ROTUNDFOLIA*
- g. Found throughout the state; mature prickles black throughout (green or brown on young stems), terete (round in cross-section) and bristle-like; peduncle 15–65 mm. long, much longer than the leaf-stalk (petiole) from whose axil it arises; fruit black; seed 1 in each berry 5. *S. TAMNOIDES* var. *HISPIDA*

1. ***Smilax pulverulenta*** Michx. Carrion-flower
Map 651
Flowers April–May.

Occurs in rich or rocky woods in the Ozark section of the state north to Washington, Osage, and Cooper counties, west to Polk and Jasper counties.

Ranges from Georgia, Tennessee, and Arkansas, north to New York, Pennsylvania, West Virginia,

Ohio, Indiana, Illinois, and Missouri. The perianth is often described as being 4–6 mm. long, but in the dried specimen is frequently only 2.5–3 mm. long.

This appears to be a species quite distinct from *S. herbacea*, as indicated by the thinner, long-acuminate leaves, which are shining and rich green on both sides, erose-ciliate on the margins, and by the relatively fewer-flowered inflorescence with black fruits.

2a. ***Smilax herbacea* L. var. *herbacea***

Carrión-flower

Map 652

Smilax herbacea L. [G, P & S]

Flowers May–June.

Occurs in rich or rocky woods and thickets. Scattered and much less common in Missouri than the var. *lasioneura*.

Ranges from New Brunswick and Quebec, south to Georgia, Tennessee, and Missouri.

2b. ***Smilax herbacea* var. *asioneura* (Hook.)**

A. DC. Carrión-flower

Map 652

Smilax lasioneura Hook. [G]

Flowers May–June.

Occurs in rich or rocky woods and thickets. Common throughout Missouri, except apparently absent in the southeastern lowland section.

Ranges from Ontario and Ohio to Minnesota, Saskatchewan and Montana, south to Georgia, Arkansas, Oklahoma, and Colorado.

The leaves are usually gray, rarely green beneath and the petioles vary from 1.2–9 cm. in length. The berries usually have a bluish-black color and are coated with a grayish 'bloom' (glaucous).

The two varieties of *S. herbacea* here enumerated are frequently found side by side or in the same location. They do not appear to merit specific segregation, as treated by Fernald in the eighth edition of *Gray's Manual*. Miss Bernice M. Speese, who has studied the group most recently, treats *S. lasioneura* in the varietal category.

The young tender shoots of these two varieties, as well as of *S. pulverulenta*, may be cooked in early spring and eaten as asparagus.

3. ***Smilax ecirrhata* (Engelm.) Wats.**

Carrión-flower

Map 653

Flowers May–June.

Occurs in rich woods in ravines, at the base of bluffs, and along streams. Common throughout northern and central Missouri, and scattered southward, becoming rare or absent in most of the Ozark section; absent also from the southeastern lowland section.

Ranges from Ontario to Minnesota and South Dakota, south to Tennessee and Missouri.

The lower surface of the leaves is gray-hairy in much the same manner as in *S. herbacea* var. *lasioneura*. The mature leaf-blades of *S. ecirrhata*, however, are much broader, becoming broadly ovate to nearly round, and with a heart-shaped to rounded base. They also average larger, attaining a length of 18 cm. and a width of 12 cm. The inflorescences in *S. ecirrhata* are

also fewer-flowered in both the male (less than 25 flowers) and female (less than 20 flowers) plants than those of *S. herbacea*, in which the inflorescences are usually 30–110-flowered in both male and female plants.

Some descriptions of *S. ecirrhata* give the berry of this species as being 3-seeded. Observations of Missouri and other specimens indicate a berry with 1–6 seeds.

Although some students of the genus seem inclined to combine this species with *S. herbacea* as a variety, the two are mainly quite distinct in their habit of growth and in other characters presented above and in the key. Usually the stems of *S. ecirrhata* remain low and erect.

4. ***Smilax glauca* Walt. Greenbrier, Catbrier**

Map 654

Flowers May–June.

Occurs in acid soils of chert, sandstone, or granite in rocky woodland, wooded valleys and moist ground along streams, open ground in cultivated or fallow fields, along fence rows, open banks, and roadsides, often becoming a persistent weed.

Missouri material is represented by two variations:

Lower surface of leaves covered with minute hairs or projections (use magnifying lens of 10 ×) .

4a. *S. GLAUCA* var. *GLAUCA*

Lower surface of leaves glabrous (hairless) or smooth (use magnifying lens of 10 ×) . . .

4b. *S. GLAUCA* var. *LEUOPHYLLA*4a. ***Smilax glauca* var. *glauca***

Map 654

Smilax glauca Walt. [G]*Smilax glauca* var. *genuina* Blake [P & S]

Known from Cape Girardeau, Madison, Carter, and Dunklin counties.

Ranges from Florida to Texas, north to New Jersey, West Virginia, Ohio, Indiana, Illinois, and Missouri.

4b. ***Smilax glauca* var. *leuophylla* Blake**

Map 654

This is the commoner variety in Missouri, found throughout the southeastern lowland section north into the southeastern Ozark section to Ste. Genevieve and St. Francois counties, west to Iron, Reynolds, Carter, and Oregon counties.

Smilax glauca is a handsome vine, becoming more or less evergreen; the leaves which remain on the stem through the winter have a greenish coppery upper surface. The dark green upper surface of the leaves is sometimes blotched or marked with white or gray throughout the growing season. The bluish-gray or

654 • *Smilax glauca* var. *glauca* (Greenbrier)654 x *Smilax glauca* var. *leuophylla* (Greenbrier)655 • *Smilax tamnoides* var. *hispida* (Bristly Greenbrier)656 • *Smilax Bona-nox* var. *Bona-nox* (Catbrier)656 □ *Smilax Bona-nox* var. *hederacfolia* (Catbrier)

whitish lower surface of the leaf-blades imparts a striking color contrast to the leaves of this species, which are definitely whiter beneath than those of any other species in Missouri, while the stems are definitely more slender than those of the other spiny-stemmed species of Missouri.

An amber-colored sweet jelly is obtained from the slender rootstocks, which have been cut up, boiled, and had sugar added in equal bulk. This jelly can be mixed with water to make a sweet drink.

5. ***Smilax tamnoides* L. var. *hispida* (Muhl.)**

Fern. Bristly Greenbrier, Catbrier Map 655
Smilax hispida Muhl. [BB, P & S]
Flowers May–June.

Occurs in low woods in valleys and thickets, along banks of streams, and on rich wooded slopes. The most common species of woody greenbrier in Missouri, where known from practically every county in the state.

Ranges from New York and Ontario to Minnesota and South Dakota, south to Georgia, Alabama, Arkansas, and Texas.

The older stems of this catbrier are covered with numerous, crowded spines, presenting a very bristly appearance.

Smilax tamnoides var. *hispida* has the leaves ovate, elliptic, or somewhat round, whereas *S. tamnoides* var. *tamnoides*, occurring mostly along the Coastal Plain, and not in Missouri, has some or all of the leaves fiddle-shaped (panduriform).

6. ***Smilax Bona-nox* L.** Catbrier, Greenbrier, Bullbrier

Map 656

Flowers May–June.

Occurs in rocky open woods, low ground in valleys and along streams, limestone glades and outcrops, in thickets, and fields. Common throughout the Ozark region north to St. Louis, Crawford, Phelps, Laclede, Webster, Christian, and Jasper counties.

Missouri material may be divided into two variations:

Leaves of flowering or fruiting stems usually mottled with white with bristlelike hairs on margins; leaf-blades mostly fiddle-shaped (panduriform) with usually short rounded lobes, the main part of the blade narrowly triangular to oblong and 1.5–4 cm. broad at the base; low plant with slender stems, rarely high-climbing . . .

6a. *S. BONA-NOX* var. *BONA-NOX*

Leaves of flowering or fruiting stems green (except rarely mottled with white on young basal sprouts), without bristlelike hairs on margins or with a few weak easily falling hairs; leaf-blades mostly broadly ovate with a heart-shaped (cordate) base, 3–8 cm. broad; plants with stouter stems, often high-climbing . . .

6b. *S. BONA-NOX*
var. *HEDERAEFOLIA*

6a. ***Smilax Bona-nox* L. var. *Bona-nox*** Map 656

Smilax Bona-nox L. [G, BB, P & S]

Scattered throughout the range in the Ozark and southeastern lowland sections.

Ranges from Mexico, and from Florida to Texas, north to Maryland, Kentucky, Indiana, Illinois, Missouri, and Kansas.

6b. ***Smilax Bona-nox* L. var. *hederacfolia***
(Beyrich) Fern.

Map 656

Plate no. 119. 1. *Smilax rotundifolia*, $\times \frac{2}{7}$; a. Female flower, $\times 1\frac{5}{7}$; b. Male flower $\times 1\frac{5}{7}$. 2. *Smilax tamnoides* var. *hispida*, $\times \frac{2}{7}$; a. Male flower, $\times 1\frac{5}{7}$; b. PLATE NO. 119

657 *Smilax rotundifolia* (Catbrier)658 *Dioscorea quaternata* (Yam)659 • *Dioscorea villosa* f. *villosa* (Yam)
□ *Dioscorea villosa* f. *glabrifolia* (Yam)

This is the more common variety encountered in Missouri (representative collections found in the Gray Herbarium at Harvard University are *Steysmark* 7749 from St. Louis County, *Steysmark* 7716 from Jefferson County, *Palmer* 22848 from Stone County, *Palmer* 32939 from Ozark County, and *Palmer* 22317, 22727, 22745 from Jasper County).

Ranges from Florida to Texas, north to Delaware and Massachusetts, Tennessee, Illinois, Missouri, and Kansas.

It is possible that future detailed studies on the variability in the leaves of *S. Bona-nox* may show that the above varieties are correlated with stages of maturity of the plant, as noted in the leaf variations found in some of the tropical aroids, such as *Synгонium podophyllum*. In the present treatment both varieties are accepted, pending further study of living plants.

The root of this and other prickly-stemmed species in Missouri may be used in the preparation of a root-beer-like (sarsaparilla) drink, in which molasses and sassafras are some of the added ingredients.

Where *S. Bona-nox* is plentiful, it often impedes walking, the tangled prickly stems tearing or catching the clothes and making it necessary to detour around these thickets. It is especially troublesome on the dry rocky Ozark slopes and in the wet thickets and forests of the southeastern lowlands.

7. *Smilax rotundifolia* L. Greenbrier, Catbrier

Map 657

Smilax rotundifolia var. *quadrangularis* (Muhl.) Wood [P & S]

Flowers late April–May.

Occurs in mostly alluvial soils of low ground along streams or in valleys, and in wet woodland and thickets. Southeastern Missouri, mainly in the southeastern lowland section northeast to Cape Girardeau and Bollinger counties, and extending into a limited section of the southeastern Ozarks northwest to Madison County, and west to Oregon County. A specimen from Pike County (Norris Farm at Eolia) collected by Reverend John Davis is undoubtedly taken from a cultivated plant.

Ranges from Florida to Texas, north to Nova Scotia, Maine, New York, Ontario, Ohio, Illinois, Missouri, and Oklahoma.

The tender young or new shoots may be eaten raw or cooked either for use as a boiled vegetable like asparagus or for a salad, said to suggest the flavor of Alligator Pear (*Persea*). The tender shoots of the other prickly-stemmed species should likewise be tried. As in *S. glauca*, the boiled rootstocks, to which sugar has been added in equal bulk, makes a brown sweet jelly. As with *S. Bona-nox*, the root may be used in the preparation of a rootbeer-like drink.

DIOSCOREACEAE (Yam Family)

Dioscorea L. Yam

- a. At least the lower leaves in whorls (circles) of 4–7; dried underground rootstocks 10–15 mm. thick, very irregularly contorted or with many short, knob-like or stubby lateral branches; seeds 17–18 mm. broad 1. *D. QUATERNATA*
- a. The lowest leaves in whorls of 3 (rarely 4) or all the leaves alternate; dried underground rootstock 5–8 (up to 10) mm. thick, comparatively straight and linear with few or no lateral branches (the older rootstocks with some lateral branches); seeds 7–12 mm. broad 2. *D. VILLOSA*

1. **Dioscorea quaternata** (Walt.) J. F. Gmel. Yam
Map 658

Dioscorea quaternata var. *glauca* (Muhl.) Fern.

Dioscorea glauca Muhl.

Flowers late April–early June.

Occurs in rich or rocky woods along bluffs, on talus slopes, and in thickets. Eastern and southern Ozark region, where found north to St. Louis and Crawford counties, and west to Texas and Taney counties.

Ranges from Pennsylvania to Indiana, Illinois, and Missouri, south to Florida, Louisiana, and Oklahoma.

Capsules in Missouri material vary from 2–3 cm. long. The leaves vary from green on both sides to paler green or silvery-gray beneath. Such paler-leaved types were at one time separated as var. *glauca*.

2. **Dioscorea villosa** L. Yam
Map 659

Flowers late April–June.

Occurs in rich or rocky woods and thickets, in ravines, on slopes, at the base of bluffs, and in valleys.

Missouri material is represented by two variations:

Nerves on the lower side of the leaf-blades with short hairs 2a. *D. villosa* f. *villosa*
Nerves on the lower side of the leaf-blades glabrous (without hairs) 2b. *D. villosa* f. *glabrifolia*

2a. **Dioscorea villosa** L. f. **villosa** Map 659

Throughout Missouri and probably in every county. This is the commoner form in the state.

Ranges from Massachusetts to Minnesota, south to Virginia, Ohio, Tennessee, Arkansas, and Texas.

2b. **Dioscorea villosa** f. **glabrifolia** (Bartlett) Fern.
Map 659

Dioscorea villosa var. *glabrifolia* (Bartl.) Stone [P & S]

Scattered over the state throughout the range of f. *villosa*.

In Missouri material of *D. villosa* the larger leaves may attain a length of 14 cm.

AMARYLLIDACEAE (Amaryllis Family)

As in the Liliaceae, the present treatment follows that of Fernald in the eighth edition of *Gray's Manual* and of Gleason in the *New Britton & Brown Illustrated Flora*. Some botanists, following Hutchinson, as indicated in the Liliaceae section of this flora, separate the Liliaceae from the Amaryllidaceae on the basis of the type of inflorescence and presence of bracts instead of on the traditional superior *vs.* inferior ovary. As such, the Amaryllidaceae includes those plants having the inflorescence in the form of an umbel subtended by an involucre of one or more usually papery bracts or spathes; sometimes the inflorescence is reduced to a single flower, but bracts or a spathe are present. Such a treatment would include *Allium* and *Nothoscordum* in the Amaryllidaceae instead of Liliaceae. Moreover, another family, Agavaceae, is recognized by some botanists to include 1) *Agave*, traditionally placed in the Amaryllidaceae, and 2) *Yucca*, traditionally placed in the Liliaceae.

In the present work the usual arrangement, following the Engler-Prantl system, adopted by many botanists, is maintained, so *Agave* is to be found in the Amaryllidaceae, and *Yucca*, *Allium*, and *Nothoscordum* have been kept in the Liliaceae.

- a. Outside of flower and flower-stalks (pedicels) hairy; foliage often hairy 4. HYPOXIS
- a. All parts of the plant glabrous (without hairs) b
- b. Leaves mostly broadest in the lower half, conspicuously narrowed to a pointed tip, mostly lanceolate; margins (edges) of leaves usually roughened with minute teeth or projections; tall plants, the flowering stem 1–2 meters high, without a bulb; flowers or fruit arranged in a long narrow spike 5. AGAVE
- b. Leaves of about the same width throughout with more or less parallel sides, usually linear or strap-shaped, only gradually narrowed to a short or rounded tip; margins of leaves smooth, without fine teeth; smaller plants, at most 0.7 meter high, arising from a bulb; flowers or fruit solitary or 2 or more in an umbel c
- c. Flowers or fruit sessile (without a separate stalk or pedicel), attached directly to the main flower-stem (scape); summer-flowering (July–August) native plants of the lowlands of southeastern Missouri; flower erect with entirely white perianth and crown 2. HYMENOCALLIS
- c. Flowers or fruit on separate stalks or pedicels before being connected with the main flower-stem (scape); spring-flowering (April–May) garden plants escaped from cultivation, throughout Missouri; flowers nodding or loosely spreading d
- d. Perianth white with green tips to the segments; flower with a bell-shaped perianth, without

660 *Narcissus poeticus* (Poet's Narcissus)

661 *Hymenocallis occidentalis* (Spider Lily)

662 *Leucojum aestivum* (Snowflake)

- a slender tube or crown; flowers 2-several hanging from the main flower-stem (scape) . 3. **LEUCOJUM**
d. Perianth white with a red- or buff-margined yellow cup, or completely yellow, or yellow
and white; flower with a slender tube and cup-like crown; flowers usually 1, rarely 2 on
the main flower-stem (scape) 1. **NARCISSUS**

1. **Narcissus** L. Narcissus

- Flower yellow, the crown about as long as or longer than the spreading perianth-segments 1. **N. PSEUDO-NARCISSUS**
Flower with a shallow cup-like red- or buff-margined yellow crown which is much shorter than the
white spreading perianth-segments 2. **N. POETICUS**

1. **Narcissus Pseudo-Narcissus** L. Daffodil

Map 660

Flowers February-April.

Commonly planted in gardens throughout Missouri. Occasionally escaping into grassy open or shaded banks and thickets.

Native of Europe.

2. **Narcissus poeticus** L. Poets' Narcissus

Map 660

Flowers April-May.

Commonly planted throughout Missouri, and occasionally escaping from gardens and cemeteries to roadsides, open woods, meadows, and vacant ground. Known as definitely established in Stoddard County (base of sandy wooded slopes across from Triplett cemetery, T₂₅N, R₁₁E, northwest $\frac{1}{4}$ sect. 6, $3\frac{1}{2}$ mi. southeast of Bloomfield, April 25, 1955, *Steyermark* 78305) and probably in many other counties.

Native of Europe.

This is the last of the *Narcissus* group to flower in Missouri.

2. **Hymenocallis** Salisb. Spider Lily

Hymenocallis occidentalis (Le Conte) Kunth

Spider Lily Map 661

Flowers July-late August. Flowering times have been recorded on July 23, 29, August 2 and August 20-21.

Occurs in mucky soil of bald cypress swamps, and swampy woodland in level low ground, often persisting in open fields of cut-over land. Restricted to the southeastern lowland section of the state, where it extends north to Cape Girardeau, Bollinger, and Wayne counties, and west to Ripley County.

Ranges from Georgia to Alabama, north to Kentucky, southern Indiana, southern Illinois, and southeastern Missouri.

The beautiful, showy white flowers are very fragrant, the fragrance lasting during the evening. The species does well in cultivation. It requires a long growing season and succeeds better in the southern portion of the United States. The author has transplanted it to his wildflower preserve northwest of Chicago, where the much shorter growing season curtails the time required by this species for certain flowering. The flower buds at this northern garden often appear too late or are killed by early frosts. Only twice in the past twelve years have flowers developed and matured.

The leaves usually persist during the period of development of the fruit which begins late in August

The flowering scape is compressed and 2-sided. The plant is often found in woodland dominated by *Populus heterophylla*, *Acer rubrum* var. *Drummondii*, *Cornus foemina*, *Quercus lyrata*, *Q. Michauxii*, *Fraxinus tomentosa*,

and *Cephalanthus occidentalis*, associated with such plants as *Iris fulva*, *Carex gigantea*, *Scutellaria lateriflora*, *Lysimachia radicans*, and *Bignonia capreolata*.

3. **Leucojum** L. Snowflake

Leucojum aestivum L. Snowflake Map 662
Flowers April-May.

Commonly planted in gardens, and rarely escaped from cultivation. Known only from St. Charles County (Weldon Springs, Busch Wildlife Area, April, 1957, Bruce Dowling, in University of Missouri Herbarium).

Native of Europe. Established and naturalized also in Maine, New York, Delaware, Missouri and else-

where.

The flowers in the Missouri specimen cited vary from 1.1 cm. in anthesis to 2.5 cm. in post-anthesis with the perianth segments 1.5 cm. long in post-anthesis. The specimen seems intermediate between typical *L. aestivum* var. *aestivum* with flowers about 2.5 cm. long and var. *pulchellum* with flowers only 1.2 cm. long.

4. **Hypoxis** L. Star Grass

Hypoxis hirsuta (L.) Coville Yellow Star Grass Map 663

Flowers mostly April-May, occasionally later until October.

Occurs in prairies, meadows, rocky glades, and dry open woods, in acid soils. Common throughout Missouri, except absent in most of the southeastern lowland section.

Ranges from Florida to Texas, north to Maine, New York, Ohio, Indiana, Wisconsin, Manitoba, and North Dakota.

The following 2 variations occur in Missouri:

Main flower-stem (scape), flower-stalks (pedicels), outside of sepals and petals, and fruit sparsely or short-hairy, becoming nearly hairless (glabrate)

a. *H. hirsuta* f. *hirsuta*

Main flower-stem (scape), flower-stalks (pedicels), outside of sepals and petals, and fruit densely or noticeably hairy with crowded hairs 3-4 mm. long

b. *H. hirsuta* f. *villosissima*

a. **Hypoxis hirsuta** f. **hirsuta** Map 663

This is the rare form in the state and is known only from St. Louis and Marion counties.

b. **Hypoxis hirsuta** f. **villosissima** Fern.

Map 663

This is the common form in Missouri.

Excluded Species

Hypoxis leptocarpa Engelm.

Hypoxis hirsuta var. *leptocarpa* (Engelm.) Brackett [P & S]

This was recorded by Palmer and Steyermark in their *Annotated Catalogue* based on a specimen from Ste. Genevieve County, southeastern Missouri (low woods along Jonca Creek, May 30, 1933, Steyermark 8800). It shows a sparsely pubescent calyx, but generally pubescent pedicels and peduncles, and is best placed with *H. hirsuta* f. *villosissima*.

5. **Agave** L. American Aloe

Agave virginica L. False Aloe Map 665

Also called Rattlesnake-master, a name used likewise for *Eryngium yuccifolium*, a member of the Umbelliferae or Carrot Family.

Flowers late June-August.

Occurs on rocky open glades, usually of limestone, and in rocky chert or sandy open woods in mostly dry upland ridges or flats, occasionally in low ground along streams; usually in alkaline soils on limestone, but

also found in acid leached sandy and cherty soils. Restricted to the Ozark section of southern and east-central Missouri, where it extends north to St. Louis, Franklin, Phelps, Pulaski, Laclede, Greene, and Jasper counties.

Ranges from Florida to Texas, north to North Carolina, West Virginia, Ohio, Indiana, Illinois, and Missouri.

Missouri material is represented by two variations:

663 *Hypoxis hirsuta* (Yellow Star Grass)

664 Excluded species

665 • *Agave virginica* f. *virginica* (False Aloe)
665 □ *Agave virginica* f. *tigrina*

666 • *Iris cristata* (Crested Iris)
666 □ *Iris cristata* var. *alba*

Leaves green throughout or mostly so
A. VIRGINICA f. VIRGINICA
Leaves with some purplish spots or mottling
A. VIRGINICA f. TIGRINA

Agave virginica L. f. **virginica** Map 665
Agave virginica L. [G, BB, P & S]
Agave lata Shinnery [Shinnery]
This is the common type encountered in Missouri.

Agave virginica f. **tigrina** (Engelm.) Map 665
Palmer & Steyerger.
This form occurs infrequently within the Missouri range, and is definitely known only from Perry and Texas counties.

Shinnery separates (*Spring Flora of Dallas-Fort Worth Area, Texas*, p. 92, 1958) *A. virginica* from *A. lata* as follows:

Leaves 12-18 cm. long, 2-7 cm. wide; perianth (including ovary) 2.6-3.5 cm. long; anthers 1.3-1.5 cm. long A. LATA
Leaves 12-30 cm. long, 1-4.5 cm. wide; perianth

(including ovary) 2-2.3 cm. long; anthers 0.8-1 cm. long. A. VIRGINICA

On the basis of measurements of both living and dried material, Missouri material combines the characters of *A. virginica* and *A. lata* to such an extent that no correlation can be found, broad-leaved individuals with smaller flowers and narrow-leaved individuals with larger flowers occurring throughout the range. It is possible, therefore, to find a more or less complete series of overlapping in the characters given by Shinnery, and, although specimens answering in part to the description of *A. lata* are found in Missouri, they cannot be accepted, at least for Missouri, as significant variations.

The flowers are fragrant, possessing a scent reminiscent of Easter Lily. The perianth is mainly greenish-yellow tinged on the outside of the lanceolate erect lobes with pale madder-brown or brick color. The filaments are yellow and the anthers gray or straw-colored.

IRIDACEAE (Iris Family)

- a. Flowers with the sepals and petals much different in shape, size, and position, the 3 petals usually upwardly pointing or spreading, the 3 sepals drooping or downward spreading; the 3 style branches large, broad, and petal-like, hiding the stamens; leaves mostly 8-30 mm. broad 1. IRIS
- a. Flowers with all 6 divisions regularly spread outward and more or less similar in shape, size, and position; the style branches or style not large, broad, nor petal-like; leaves mainly 1-11 mm. wide, or when wider, the roots and rhizome orange, the fruiting heads resembling a blackberry, and the perianth orange-red or salmon with brown-purple spots. b
- b. Plant with iris-like leaves 16-25 mm. broad; roots and rhizome orange; perianth orange-red or salmon with brown-purple spots; fruit blackberry-like with fleshy black seeds. 3. BELAMCANDA
- b. Leaves not iris-like, much narrower, 1-11 mm. broad; roots or underground parts not orange; perianth blue, purple, white, or rarely yellow; fruit not as above c

- b. Plants of more moderate height, the combined stems and leaves 30–90 cm. tall at flowering time; flowering usually in late April–June c
- c. Bracts (spathe-valves) which enclose buds and remain at base of open flowers mainly green on lower portion, scarious (thin, dry, and transparent) along margin and summit 3. *I. GERMANICA*
- c. Bracts (spathe-valves) which enclose buds and remain at base of open flowers completely silvery-scarious (thin, dry, and transparent) throughout 4. *I. PALLIDA*
- a. The 3 spreading to drooping sepals without a strip or beard of long hairs down the middle d
- d. Plants (with the leaves) usually less than 20 cm. tall while in flower, without a definite upright stem; rootstocks slender with alternate constrictions and thickenings and creeping close to the surface of the ground; flowering mainly in late April to early May; the 3 sepals with a fringed crest 1. *I. CRISTATA*
- d. Plants (with the leaves) 20–100 cm. tall while in flower, with a conspicuous upright stem; rootstocks thickened uniformly and not creeping close to the surface of the ground; flowering from late April–July; the 3 sepals without any crest e
- e. Flowers orange, brick-brown, or copper-colored, or deep yellow f
- f. Flowers deep yellow; sepals and petals of quite different lengths; ovary and capsule bluntly 3-angled; plants introduced from cultivation 6. *I. PSEUDACORUS*
- f. Flowers orange, brick-brown, or copper-colored; sepals and petals of nearly the same length, the petals slightly smaller; ovary and capsule 6-angled; native plants of the lowlands of southeastern Missouri 7. *I. FULVA*
- e. Flowers some shade of blue, lavender, or purple g
- g. Flowers in the lower part of the plant, appearing hidden among the leaves, the leaves much longer than the flowers and flower-stem; stem (bearing the flowers or fruit) short, somewhat zigzag, mostly 10–35 cm. high; ovary and capsule 6-angled; rare plants mostly of low rich woods, at the base of wooded slopes, or bordering wooded sloughs and streams 8. *I. BREVICAULIS*
- g. Flowers at the top of an elevated stem, plainly visible, most of leaves either shorter, or equal, or slightly longer than the flowering stem; stems (bearing the flowers or fruit) elongated, straight, mostly 40–100 cm. high; ovary and capsule bluntly 3-angled; common plants chiefly of open swampy or wet ground of meadows, river bottom prairies, swales along railroads, and other open wet areas, throughout Missouri 5. *I. VIRGINICA* var. *SHREVEI*

1. *Iris cristata* Ait. Crested Iris, Dwarf Wild Iris
Map 666

Flowers April–early May.

Occurs on rocky wooded slopes and along bluffs, in cherty or limestone soils, and along sandy banks of streams. Restricted to the southeastern Ozark section in Shannon, Oregon, Reynolds, Carter, Ripley, Wayne, and Butler counties, and locally east in Scott County (*Steyermark 76890*).

Ranges from D. C. to Indiana and Missouri, south to North Carolina, Alabama, Mississippi, Arkansas, and Oklahoma.

The alternately constricted and enlarged parts of the creeping rhizome are characteristic of this species. It thrives in shaded rock gardens, preferring well-drained slopes. In the author's wildflower garden it has multiplied by the hundreds. The usual color of the flowers is lilac to lavender, the sepals having a

PLATE NO. 121

667 *Iris pumila* (Dwarf Iris)668 *Iris germanica* (German Iris)669 *Iris pallida* (Flag)

yellow or whitish crest with a white area bordered below with violet or deep purple. The petal-like style branches are pale lilac with deep lavender or purple forking or lobed tips. A rare form with the flowers all white except for the yellow crest is known as var. *alba* Dykes. It has been found in Missouri by Mr. Bill Bauer on property adjoining Big Spring State Park, Carter County, in 1937, but has not been recorded from any other locality in the state.

2. ***Iris pumila* L.** Dwarf Iris Map 667
Flowers late March–April.

Commonly planted in rock and other gardens throughout Missouri, but rarely escaped from cultivation. Known definitely as established in Washington and Boone (waste fields west of Columbia, April 16, 1902, *Paul Hayhurst*, in University of Missouri Herbarium) counties.

Native to Europe and Asia Minor.

The usual color of the flower is a dark reddish-purple with a bluish or yellow beard. Various other colors may occur, including one with yellow flowers (var. *flaviflora* Fuss).

3. ***Iris germanica* L.** German Iris, Blue Flag Map 668
Flowers April–June.

Commonly grown as a garden flower throughout the state, but rarely naturalized.

Known definitely as an escape from cultivation in St. Louis (Burlington R. R., north of E. Grand Ave., St. Louis, April 30, 1955, *Muehlenbach* 530), Lawrence (*Palmer* 55490), and Butler (*Huron Smith* 629) counties.

Native to Europe.

Numerous garden varieties have originated from this species, which is one of the sources of orris-root used as an ingredient in perfumes. The flowers are usually lilac to purple, varying to white, the sepals usually a dark purple with a yellow beard.

The Muehlenbach specimen has been interpreted

by Dr. Edgar Anderson as probably representing a hybrid between *I. pallida* and *I. variegata* L. The latter species is considered to be the probable ancestor of much of the *I. germanica* group.

4. ***Iris pallida* Lam.** Flag Map 669
Flowers April–June.

Like *I. germanica*, commonly grown as a garden flower throughout Missouri. Rarely escaping and established in Washington, Boone, and Vernon counties.

Native of Europe and Asia.

The flowers are purple, varying to white with a yellow beard. This species and *I. germanica* are often confused. From the rootstocks of this species is obtained an essential oil, which has an odor of violets (*Viola*) and often used in a tincture of orris-root to impart a fragrance to violet perfume, while the dried root is the basis of violet face powder.

5. ***Iris virginica* L. var. *Shrevei*** (Small) Map 670
E. Anders. Southern Blue Flag
Iris Shrevei Small [BB]
Iris virginica [of P & S], not L.
Flowers late May–early July.

Occurs mostly in open swampy or wet ground of meadows, river bottom prairies, swales along railroads, ditches, and borders of ponds and sloughs of river valleys. Common throughout northern and central Missouri and scattered elsewhere in the state; not recorded from a large sector of western Missouri south of the Missouri River.

Typical *I. virginica* var. *virginica* has capsules which average shorter, 3–7 cm. instead of 5–10 cm. long, and they are ovoid or ellipsoid instead of long-cylindric as in var. *Shrevei*.

Some persons are reported as getting dermatitis from handling the rootstocks and other parts of this species. The rootstock possesses an irritant substance which, when eaten, can cause complications in the digestive tract, leading to mild cases of poisoning.

670 *Iris virginica* var. *Shrevei* (Southern Blue Flag)

671 *Iris Pseudacorus* (Yellow Iris)

672 *Iris fulva* (Copper Iris)

Grazing animals do not eat much of this plant because of its sharp taste.

6. ***Iris Pseudacorus* L.** Yellow Iris, Yellow Flag
Map 671

Flowers May–July.

Planted in gardens, often around pools or low wet ground, and rarely escaping or becoming naturalized in Missouri. Known definitely established only in Crawford (low woods along creek below Blue Spring, 2 mi. southeast of Bourbon, August 12, 1939, *Steyermark 27908*) and Newton (along rocky margins of Hickory Creek, Neosho, May 19, 1954, *Palmer 57567*) counties, where it grows in wet ground and low moist woods.

Native of Europe.

This is a handsome and striking species with tall erect leaves a meter or more high. The tall stems bearing the bright yellow flowers may equal or are shorter than the leaves.

7. ***Iris fulva* Ker** Copper Iris, Red Iris Map 672
Flowers late April–June.

Occurs in bald cypress swamps, borders of sloughs, bayous, and ponds, along open ditches and drainage canals, and swampy woodland. Restricted to the lowland section of southeastern Missouri, extending north to Perry County and west to Wayne and Ripley counties.

Ranges from Georgia to Louisiana, north to southern Illinois and southeastern Missouri.

This iris is a striking species when in flower, often growing nearly submerged in the water during the

flowering season. The soil often becomes dried up later on in the year.

At the author's wildflower preserve this species has prospered and produced blossoms numerous times in the fifteen years it has been growing at this locality, situated four hundred miles north of its usual range.

8. ***Iris brevicaulis* Raf.** Short-stemmed Iris
Map 673

Iris foliosa Mack. & Bush [P & S]

Flowers late May–early July.

Occurs usually in woodland habitats, of low rich valley woods bordering sloughs or streams or at the base of wooded slopes in ravines. Rare in the state, where known from portions of eastern, northern, and central Missouri; absent from most of the Ozark region and from the southwestern unglaciated prairie section.

Ranges from Alabama to Texas, north to Ontario, Ohio, Indiana, Illinois, Missouri, and Kansas.

This species may be somewhat more common than appears at present evident from the known records, since it often grows vegetatively and does not produce flowers. It is, therefore, probable that it has been overlooked by collectors when not in flower.

The flowers have a deeper blue or blue-purple than those of the other native species in the state. The yellow crest area on the sepals is prominently surrounded by a broad white zone which gives way to the remainder of the blue-purple expanded portion of the sepal. The expanded style branches are greenish white with a conspicuous lavender stripe down the middle ending in the lavender somewhat ovate crests.

2. ***Nemastylis* Nutt.** *Nemastylis*

Dr. R. C. Foster of Harvard University has identified the Missouri material and has furnished some of the data in the following key:

Flowering April–May; stems of leaves well-developed, mainly 5–11 mm. wide; filaments free or only

673 *Iris brevicaulis* (Short-stemmed Iris)674 *Nemastylis geminiflora* (Nemastylis)675 *Nemastylis Nuttallii* (Nemastylis)

slightly joined (connate) at base; flowers blue to lilac-blue, 4-7 cm. broad, opening in the morning and closing before sundown

1. *N. GEMINIFLORA*

Flowering June-July; stems of leaves reduced, or, if developed, narrow, 1-4 (-6) mm. wide; filaments completely or partially united; flowers deep lavender or pale purple, smaller, 2-3.5 cm. broad (smaller in dried specimens), opening from 5-7 in afternoon and staying open in the evening.

2. *N. NUTTALLII*

1. ***Nemastylis geminiflora*** Nutt Map 674

Nemastylis acuta (Bart.) Herb. [P & S, BB]

Flowers April 20-May 15.

Occurs on limestone glades and calcareous prairies, mostly in the eastern section of the Ozarks in Ste. Genevieve, Washington, Franklin, and Iron counties, and locally west to Cass County.

Ranges from Louisiana and Texas, north to Tennessee, Missouri, and Kansas.

2. ***Nemastylis Nuttallii*** Pickering Map 675

Nemastylis coelestina (Bartr. ex Willd.) Nutt. as to name only;

Nemastylis acuta of some authors in part [P & S], not Herb.

Flowers mainly June 1-July (flowering dates June 1, June 21, 22, 24, and early July).

Occurs in prairies, limestone glades near *Juniperus* trees, cherty open woods near limestone slopes above bluffs along streams, cherty slopes just above contact with limestone glades, and post oak-white oak-*Andropogon* covered slopes along bluffs, mostly in the southwestern sector of the Ozarks from McDonald

County east to Ozark County and north to Franklin (Steyermark 41039), Phelps (Steyermark 70906, 71752), Laclede, and Dallas counties.

Ranges from Missouri to Arkansas and Oklahoma.

This species has smaller, more lavender to purple flowers, and blooms later in the season (June 1, June 21, 22, 24, and July flowering dates) than *N. geminiflora*.

According to the author's field observations, this species may occur more frequently in more acid soils than does *N. geminiflora*. The latter species in the eastern Ozarks is on calcareous open glades, whereas *N. Nuttallii* has been collected more frequently in cherty soils in grassy oak chert ridges near the zone of contact of the chert with the limestone. It is also found on the limestone glade proper frequently with red cedar and with other limestone glade plants, such as *Penstemon Cobaea* var. *purpureus*, *Parthenium hispidum*, and *Baptisia minor*, so that it may occur in both situations. At the virgin prairie in Phelps County, where it was common, the soil is slightly acid. More field work needs to be done regarding the soil differences of these species.

3. ***Belamcanda*** Adans. Blackberry Lily

Belamcanda chinensis (L.) DC. Map 676

Flowers early July-August.

Occurs in rocky open woods, thickets, limestone

glades, limestone ledges and pockets of bluffs. Throughout Missouri, where it has escaped from cultivation in old gardens and become established.

Plate no. 122. 1. *Sisyrinchium Bermudiana*, $\times \frac{2}{7}$; a. Fruiting plant, $\times \frac{2}{7}$. 2. *Sisyrinchium atlanticum*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 3. *Sisyrinchium campestre*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 4. *Nemastylis geminiflora*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 5. *Belamcanda chinensis*, $\times \frac{2}{7}$; a. Map 678

Sisyrinchium campestre Bickn. [G, BB, P & S]

This is the common type encountered in the state.

2b. ***Sisyrinchium campestre* f. *kansanum***

(Bickn.) Steyermark

Map 678

Sisyrinchium kansanum (Bicknell) Alexander [BB];

Sisyrinchium campestre var. *kansanum* Bicknell [P & S].

This white-flowered form is known from several counties in southwestern Missouri, but is not known elsewhere in the state.

In Gleason's *New Illustrated Flora* (1: 451. 1952) it is treated as a distinct species, distinguished by the glabrous instead of scabridulous (minutely rough-hairy) spathe-values. I have not been able to use this character in distinguishing the southwestern Missouri material from the other *S. campestre* in the state, and have relegated it to a form under *S. campestre*.

2c. ***Sisyrinchium campestre* f. *flaviflorum***

(Bicknell) Steyermark

Map 678

Known originally only from post oak woods in Jackson County, west-central Missouri, where collected by Bush. The only other known collection is one recently made in Lawrence County, southwestern Missouri (swales in upland prairie, 5 mi. east of Sarcxie, May 10, 1951, *Palmer* 51785).

3. ***Sisyrinchium Bermudiana* L. em. Fernald**

Blue-eyed Grass

Map 679

Sisyrinchium angustifolium Mill. [G]

Sisyrinchium graminoides Bicknell [BB, P & S]

Flowers May-July.

Occurs mostly in woodland, frequently in wooded valleys in moist soil along streams or on wooded slopes and thickets, less frequently in more open situations. Found throughout Missouri, but absent from most of northwestern Missouri and some northern and central counties.

Ranges from Florida to Texas, north to Newfoundland, Quebec, Ontario, Ohio, Indiana, Illinois, Missouri, and Kansas.

Dr. Shinners (Rh. 59: 159. 1957) has recently shown that the correct name for this species is *S. Bermudiana*.

4. ***Sisyrinchium atlanticum* Bickn.**

Blue-eyed Grass

Map 680

Flowers late April-June 19.

Occurs in acid soils of low sandy prairies, wet prairie swales of upland, and wet upland open meadows bordering sink-hole ponds. Rare and scattered in the southeastern third of the state, in Scott, Mississippi (*Steyermark* 10294), Phelps (*Steyermark* 71633), and Howell (*Steyermark* 40028) counties.

Ranges from Florida to Mississippi, north to Nova Scotia, Maine, New Hampshire, Vermont, and southeastern New York, and in the interior in Ohio, Indiana, Michigan, Illinois, and Missouri.

This species is typically one along or near the coastal plain. The stations where it is found in Missouri are from localities whose flora shows ancient connections with the Atlantic and gulf coastal plain vegetation.

The conspicuously forking stems with long slender peduncles and the very glaucous leaves and stems are notable features of this species.

Order SCITAMINALES

Fam. MARANTACEAE (Arrowroot Family)

Thalia L.***Thalia dealbata*** Roscoe *Thalia*

Map 681

Flowers July 7–August 25.

Occurs along drainage canals, open swamps, and natural lakes in the lowland section of southeastern Missouri, where it is known from Ripley, Butler, Stoddard, Scott, and Cape Girardeau counties.

Ranges from Florida to Texas, north to South Carolina and southeastern Missouri.

This is often grown as an ornamental plant for outdoor pools and pond margins in St. Louis and elsewhere in the state, as well as a greenhouse plant. Its large ovate-lanceolate, long-petioled leaves are covered with a white powdery coating which covers all parts of the plant. The flowers are blue and purple

and arranged in an open panicle.

Earlier collectors in Missouri had found this plant only in swamps around Poplar Bluff and Neeleyville, in Butler County. More intensive collecting in the state has revealed a wider distribution in the southeastern lowland section where it reaches the known northwestern limits of natural range. Its natural habitat is in swamps and lakes associated with *Zizaniopsis miliacea*, *Ludwigia glandulosa*, *Hydrolea ovata*, *Polygonum hydropiperoides* var. *opelousanum*, and *Hypericum Walteri*. Such natural lakes occur in those sections of the southeastern lowland forest where Bald Cypress, Swamp Tupelo, Swamp Cottonwood, and Swamp Red Maple are abundant.

Order ORCHIDALES

ORCHIDACEAE (Orchid Family)

- a. No leaves present at flowering time *b*
- b. Flowers all or nearly all white or creamy-white (some green or yellow may be present on the lip), in a more or less spirally twisted inflorescence; flowers sessile (without a stalk); lip (largest lower division) without ridges 9. SPIRANTHES
- b. Flower of other colors, not spirally twisted; flower on short or long stalks; lip (largest lower division) with 1 or more ridges *c*
- c. Sepals about 20 mm. long; lip about 15 mm. long, with 5–7 conspicuous ridges; plants blooming July–late August; pollen masses 8 15. HEXALECTRIS
- c. Sepals 3–15 mm. long; lip 2.5–12 mm. long, with 1–3 low ridges; plants blooming February–June or July–October; pollen masses 4 *d*
- d. Sepals 10–15 mm. long; lip 10–12 mm. long; stem originating from a solid round tuber (corm) 14. APLECTRUM
- d. Sepals 3–8 mm. long; lip 2.5–6 mm. long; stem originating from a mass of coral-like or shortly branched fleshy roots 11. CORALLORHIZA
- a. Leaves present at flowering time *e*
- e. Only 1 well-developed leaf present, either on the stem or at the base of the plant. *f*
- f. Leaf present only in autumn, winter, and early spring, disappearing before or just after flowering; leaf dark green, 4 cm. or more wide 14. APLECTRUM
- f. Leaf present during and after flowering; leaf pale or grass green, 0.2–3 cm. wide *g*
- g. Leaf only 1½–2 times as long as broad, 3–6 cm. long; flowers minute, greenish; sepals 1.3–1.5 (–2) mm. long, the lip (largest petal) 2–2.5 mm. long; lateral petals linear, thread-like, 1 mm. long 12. MALAXIS
- g. Leaf mostly 3–20 times as long as broad, 3–40 cm. long; flowers rose-colored, lilac or pink with sepals 15–22 mm. long and lip (largest petal) 15–20 mm. long, or the flowers greenish with white or yellow and with sepals 2–5 mm. long and lip 3–5 mm. long; lateral petals elliptic, lanceolate, or broadly ovate, 2–22 mm. long *h*
- h. Flowers greenish with white or yellow; sepals 2–5 mm. long; lip 3–5 mm. long 3. HABENARIA CLAVELLATA
- h. Flowers mainly rose, pink, or lavender; sepals 15–22 mm. long; lip 15–20 mm. long *i*
- i. Leaf grass-like, linear, mainly 2–20 mm. wide, mainly 12–30 cm. long; sepals ending in an acute point 7. CALOPOGON

- i. Leaf lanceolate to oblong-elliptic or obovate, mainly 10–30 mm. wide, 2–9 cm. long; sepals blunt or rounded 4. *POGONIA*
- e. 2 or more well-developed leaves present, either on the stem or at the base of the plant j
- j. 5–6 (rarely up to 10) leaves arranged in a whorl (circle) at the top of the stem. 5. *ISOTRIA*
- j. Leaves not as above, but either at the very base of the plant, or arranged alternately along the stem, or at the base as well as on the stem. k
- k. Leaves only at the base of the plant l
- l. Only 2 leaves at the base of the plant m
- m. Leaves 0.3–1.5 cm. wide; flowers mostly white or cream-colored, or with some yellow or green on the lip (largest lower division), in a more or less spirally twisted inflorescence; flowers sessile (without stalks) 9. *SPIRANTHES*
- m. Leaves 2–7 cm. wide; flowers of other combinations, either lavender and white, or purple-brown or lavender with green or yellow-green; flowers on short or long stalks (pedicels) n
- n. Upper half of flower purple or lavender, lower half (lip) white; leaves very dark green; flower-stem arising from a cluster of long fleshy roots 2. *ORCHIS*
- n. Flowers either mostly brown-lavender or purple-brown with some parts greenish or flowers yellowish-green throughout; leaves olive- or grass green; flower-stem swollen at the base, arising from a rounded bulbous base 13. *LIPARIS*
- l. Several leaves arranged in a rosette at the base o
- o. Upper leaf-surface with dark green background marked with gray-white nerves and cross veins 10. *GOODYERA*
- o. Upper leaf surface plain green without a network of white venation 9. *SPIRANTHES*
- k. Leaves mainly on stem, alternately arranged, or both on the stem and at the base of the plant p
- p. All the leaves of stem very small and ovate, 6–18 mm. long, 5–8 mm. wide; flowers white and lavender-pink 6. *TRIPHORA*
- p. Without the above combination or lacking the above characters q
- q. Flowers numerous in a more or less spirally twisted inflorescence, white or creamy white, the lip with yellow, green, or white; lip (largest lower petal) 3–15 mm. long; sepals 3–14 mm. long; flowers sessile (without stalks) 9. *SPIRANTHES*
- q. Without the above combination or lacking the above characters r
- r. Flowers 1–3 to a stem s
- s. Flowers with a large showy inflated balloon-like pouch (the lip) which is 18–50 mm. long; stem or leaves or both hairy 1. *CYPRIPEDIUM*
- s. Without the above combination; lip not inflated or a balloon-like pouch, 17–22 mm. long; stem and leaves glabrous (without hairs) 4. *POGONIA*
- r. Flowers 5–many to a stem t
- t. Flowers green and purple, without any spur (downward prolonged back part of lip); lip slightly inflated or sac-like at its base; sepals and petals ending in an acute or sharp point; leaves spreading out more or less horizontally, shining, strongly nerved 8. *EPIPACTIS*
- t. Without the above combination or lacking the above characters; flower with a definite spur; lip not inflated or sac-like; sepals often blunt or rounded; leaves mainly erect or ascending 3. *HABENARIA*

1. *Cypripedium* L. Lady-slipper

- a. Sepals and lateral petals white, blunt at tip, shorter than the lip; lip rose or rose-purplish with white; plants of moist crevices of limestone bluffs along streams or in wet calcareous meadows in the Ozarks, or in rich moist woods of northern Missouri 3. *C. REGINAE*
- a. Sepals and lateral petals purplish-brown, lavender and green or greenish-yellow, slender- or long-pointed at tip, the sepals longer than the lip, the lateral petals equaling or longer than the lip; lip yellow or white with purple spots or lines toward the inside; plants of acid soils, most frequently along the upper half of steep north- or east-facing wooded oak-hickory or pine-oak slopes, less frequently on lower wooded slopes or moist prairies b
- b. Lip white, with purple dots or stripes inside, 1.8–2.3 cm. long; lateral petals 2–3 cm. long; upper sepal 2–3 cm. long; leaves 1–4 cm. wide, usually 3–4 on a stem; very rare in Missouri. 2. *C. CANDIDUM*
- b. Lip yellow, 2–5 cm. long; lateral petals 2.5–9 cm. long; upper sepal 2.5–7 cm. long; leaves

682 o *Cypripedium Calceolus* var. *parviflorum* (Small Yellow Lady-slipper)683 *Cypripedium candidum* (Small White Lady-slipper)684 *Cypripedium reginae* (Showy Lady-slipper)682 x *Cypripedium Calceolus* var. *pubescens* (Large Yellow Lady-slipper)

mostly 4–12 cm. (less frequently 2 cm.) wide, mostly 4–6 (rarely 3) on a stem; throughout Missouri except absent in southeastern lowland section 6

c. The common type in the eastern half of the state; lip large, 3–5 cm. long; lateral petals 5–9 cm. long; sepals usually greenish-yellow with purple lines; leaves 3–4 (rarely 5) on a stem.

1b. *C. CALCEOLUS* var. *PUBESCENS*

c. The common type in the western half of the state, and east in the Ozarks to Washington, Dent, Shannon, and Oregon counties; lip smaller, mainly 2–3 cm. (rarely to 4) long; lateral petals 3.5–5 cm. long; sepals dull madder purple; leaves usually 4–6 on a stem 1a. *C. CALCEOLUS* var. *PARVIFLORUM*

1a. ***Cypripedium Calceolus* L. var. *parviflorum***
(Salisb.) Fern. Small Yellow Lady-slipper

Map 682

Cypripedium parviflorum Salisb. [P & S]

Cypripedium Calceolus var. *pubescens* [of BB], not (Willd.) Correll

Flowers late April–early June.

Occurs most frequently in acid soils along the upper half of steep north- or east-facing wooded oak-hickory or pine-oak slopes along streams or valleys and in ravines, less frequently on the lower slopes. Northwestern, central, and western Missouri, and locally east in Randolph, Ralls, Boone, Callaway, Crawford, Dent, Shannon, and Oregon counties.

Ranges from Newfoundland to British Columbia, south to Georgia, Tennessee, Ohio, Indiana, Illinois, Missouri, Texas, New Mexico, Utah, and Washington.

Gleason in the *New Illustrated Flora* combines this variety with var. *pubescens*.

1b. ***Cypripedium Calceolus* var. *pubescens***
(Willd.) Correll Large Yellow Lady-slipper

Map 682

Cypripedium parviflorum var. *pubescens* (Willd.) Knight [P & S]

Cypripedium Calceolus in part [BB], not L.

Flowers late April–early June.

Similar habitats as var. *parviflorum*. Northern, central, and eastern Missouri, west to Gentry, De Kalb, Carroll, Jackson, Moniteau, Texas, and Greene counties.

Ranges from Nova Scotia and Maine to Minnesota, south to Georgia, Alabama, Tennessee, and Missouri.

The foliage turns a pale yellow-green in autumn.

As indicated by the general geographical distribution, var. *pubescens* occurs mainly in the southeastern and eastern half of Missouri, and in the eastern half of the United States, whereas var. *parviflorum* is of more western and northern range, both in Missouri and in the United States. There is intergradation between the two varieties and they are sometimes difficult to distinguish. Both are closely related to *C. Calceolus* var. *Calceolus* of Europe and Asia, and are now considered as only American varieties of this species (see Correll, Bot. Mus. Harv. Univ. Leaflets 7: 14. 1938, and Fernald, Rh. 48: 4. 1946). In their extremes the vars. *parviflorum* and *pubescens* may be rather readily distinguished, and their differences were carefully brought out by Mr. Albert M. Fuller (Bull. Pub. Mus. Milwaukee 14: 64–70. 1933. The Orchids.). The habitat differences usually indicated for the two

Plate no. 123. 1. *Thalia dealbata*, $\times \frac{2}{7}$; After Gleason, details from Small, The New York Botanical Garden. 2. *Cypripedium Calceolus* var. *parviflorum*, $\times \frac{2}{7}$. 3. *Cypripedium Calceolus* var. *pubescens*, $\times \frac{2}{7}$. 4. *Cypripedium candidum*, $\times \frac{2}{7}$. 5. *Orchis spectabilis*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 6. *Cypripedium reginae*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden.

PLATE NO. 123

Ozarks, the southeastern lowlands, and glaciated prairie sections.

Ranges from Quebec and Ontario, south to Georgia, Alabama, Tennessee, Missouri, and Kansas.

This species will grow well in a wildflower garden when provided with cool shade and rich loose soil covered with leaf-mold. The flowers are delicately fragrant.

3. **Habenaria** Willd. Rein-orchis, Fringed Orchis

- a. The lip (largest 3rd petal) fringed, deeply lobed or cut, or toothed all along the margins b
- b. Flowers orange; lip not 3-parted nor 3-lobed, the main body of the lip oblong 3. *H. CILIARIS*
- b. Flowers white, rose, lavender, purple, yellow-green, or yellow-white with bronze; lip 3-parted or 3-lobed c
- c. Flowers white or yellow-green or greenish-white with bronze; lip deeply fringed, the hair-like fringed portions as long as or longer than the main body of the lobe itself; largest leaves 0.5–3.5 cm. wide d
- d. Flowers completely white or greenish-white, the sepals and lateral petals 8–10 mm. long; lip 15–20 mm. long; spur 20–40 mm. long; lateral petals with toothed margins 5. *H. LEUCOPHAEA*
- d. Flowers mainly yellow-green or green with white or bronze, the sepals and lateral petals 4–6 mm. long; lip 7–15 mm. long; spur 10–17 mm. long; lateral petals with entire (not toothed) margins 4. *H. LACERA*
- c. Flowers rose-purple, lavender, or lilac-pink; lip shallowly toothed to deeply fringed, if deeply fringed, then the fringed portions not as long as the main body of the lobe itself; largest leaves 2–9 cm. wide e
- e. Lip shallowly toothed; the teeth 1 mm. or less long; lip 18–30 mm. broad 7. *H. PERAMOENA*
- e. Lip deeply fringed or cut, the fringed or cut portions 2–5 mm. long; lip 6–16 mm. broad 6. *H. PSYCHODES*
- a. The lip (largest 3rd petal) with mostly an entire (toothless) margin or with some teeth at tip or along margins, but not lobed, nor fringed, nor with fine teeth all along margins f
- f. Only 1 well-developed leaf on stem (rarely 2); lip with 3 shallow rounded teeth at tip; bracts shorter than the flowers 1. *H. CLAVELLATA* var. *CLAVELLATA*
- f. Mostly 2–5 leaves (rarely 1) on stem; lip with a few teeth on the margins; bracts equaling or much longer than the flowers 2. *H. FLAVA*

1. **Habenaria clavellata** (Michx.) Spreng. var. **clavellata** Green Wood Orchid Map 686
 Flowers July–August.

Occurs in swampy woodlands and spring branches of Crowley Ridge in the southeastern lowland section of Missouri, where known from Dunklin (Kennett, July 21, 1900, *Dimmitt*) and Stoddard (wooded spring branch in Crowley Ridge, T25N, R10E, northeast ¼ sect. 1, 3¼–3½ mi. southeast of Bloomfield, October

17, 1955, *Steyermark 80385*; spring branch in valley of Crowley Ridge, T25N, R10E, southeast ¼ sect. 11, 4–4¼ mi. south of Bloomfield, October 17, 1955, *Steyermark 80427*) counties.

Ranges from Florida to Texas, north to Massachusetts, New Brunswick, New York, Ohio, Indiana, Wisconsin, and Minnesota.

In Missouri this orchid is found in seepage and wet soils of spring branches of Crowley Ridge, near its

688 *Habenaria ciliaris* (Yellow Fringed Orchid)689 *Habenaria lacera* var. *lacera* (Ragged Orchid)690 *Habenaria leucophaea* (Prairie White Fringed Orchid)

junction with the swampy level lowlands proper. In such situations it is associated with the rare American Holly (*Ilex opaca*).

2. ***Habenaria flava* (L.) R.Br.**

Pale Green Orchid

Map 687

Flowers May 20–September.

Occurs in low or level woods in valleys bordering streams and swamps, and in swales of river bottom prairies.

Missouri material is represented by 2 varieties:

Inflorescence loosely-flowered; most of floral bracts shorter than the flowers, the lowest bracts equaling or slightly longer than the flowers; larger leaves of stem usually 2, less frequently 1 or 3 2a. *H. FLAVA* var. *FLAVA*
 Inflorescence compact; lowest floral bracts much longer than the flowers; the larger leaves of stem 2–5 2b. *H. FLAVA* var. *HERBIOLA*

2a. ***Habenaria flava* var. *flava***

Map 687

Known only from the southeastern Ozark section in Wayne and Shannon counties.

Ranges from Florida to Texas, north to Maryland, Kentucky, Indiana, Illinois, and Missouri; also in Nova Scotia.

2b. ***Habenaria flava* var. *herbiola* (R.Br.)**

Ames & Correll

Map 687

Occurs in northern and eastern Missouri west in the Ozark region to Howell County. It is the com-

moner variety encountered in the state.

Ranges from New Brunswick to Ontario, south to North Carolina, Tennessee, Ohio, Indiana, Illinois, Wisconsin, and Missouri.

The sepals and 2 lateral petals in *H. flava* are mostly greenish, varying to greenish-yellow and greenish-white.

3. ***Habenaria ciliaris* (L.) R.Br.**

Yellow Fringed Orchid

Map 688

Flowers July 25–October 13.

Occurs in acid soils of sandy wet springy ground along spring branches, wet wooded margins of upland sink-hole ponds, and in moist pine woods. Known only from Iron, Ripley (Pleasant Grove, *Bush*; margin of Cupola Pond, T25N, R1W, sect. 29, 1½ mi. southeast of Handy, August 19, 1951, *Steiermark* 72493), and Stoddard (base of Crowley Ridge, near junction with lowland, T25N, R11E, northwest ¼ sect. 6, 3½ mi. southeast of Bloomfield, August 20, 1954, *Steiermark* 76790).

Ranges from Florida to Texas, north to Massachusetts, Ontario, Michigan, Wisconsin, and Missouri.

This is one of the most beautiful as well as one of the rarest of orchids in Missouri. This orchid does not do well in a wildflower garden, and should remain undisturbed in its native haunts. Areas where it occurs should be rigidly protected against vandalism. The Stoddard County station, which the author discovered, has now been purchased by the Missouri Chapter of Nature Conservancy for protection to be kept

Plate no. 124. 1. *Habenaria flava*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{2}{7}$; After Britton and Brown, The New York Botanical Garden. 2. *Habenaria ciliaris*, $\times \frac{2}{7}$; a. Flower, $\times \frac{4}{7}$; After Gleason, The New York Botanical Garden. 3. *Habenaria psychodes*, $\times \frac{2}{7}$; After Gleason, The New York Botanical Garden. 4. *Habenaria lacera*, $\times \frac{2}{7}$; a. Flower, $\times 1\frac{5}{7}$. 5. *Habenaria leucophaea*, $\times \frac{2}{7}$; After Gleason, details from Small, The New York Botanical Garden. 6. *Habenaria clavellata*, $\times \frac{2}{7}$. 7. *Habenaria peramoena*, $\times \frac{4}{7}$; After Britton and Brown, The New York Botanical Garden. 8. *Pogonia ophioglossoides*, $\times \frac{2}{7}$; After Gleason, details from Small, The New York Botanical Garden. 9. *Isotria medeoloides*, $\times \frac{2}{7}$; a. Fruiting plant, $\times \frac{2}{7}$. 11. *Triphora trianthophora*, $\times \frac{4}{7}$; Details from Small, The New York Botanical Garden. 12. *Calopogon pulchellus*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden.

PLATE NO. 124

691 *Habenaria psychodes* (Small Purple Fringed Orchid)692 *Habenaria peramoena* (Purple Fringeless Orchid)693 *Pogonia ophioglossoides* (Snake-mouth)

forever in its natural state. The orange or orange-yellow flowers are arranged in a compact, many-flowered inflorescence 5–15 cm. long and 4–8 cm. thick. The inflorescence, which starts to bloom in Missouri normally around the early to middle part of August, generally continues in bloom for a period of a month, especially in woodland situations.

4. ***Habenaria lacera*** (Michx.) Lodd. var. ***lacera***
Ragged Orchid Map 689
Flowers May–early August.

Occurs in moist meadows and swales and along small streams in upland prairies, also in upland flat wet woods bordering sink-hole ponds. Southern and east-central Missouri, north to St. Louis, Audrain, and Boone counties, west to Hickory, Barton, Jasper, and Newton counties.

Ranges from the Magdalen Islands to Ontario and Minnesota, south to Florida, Alabama, Mississippi, and Texas.

Another variety, var. *terrae-novae* Fern., with smaller flowers, occurs from Newfoundland to Nova Scotia.

5. ***Habenaria leucophaea*** (Nutt.) Gray
Prairie White Fringed Orchid Map 690
Flowers June 10–July. Most of the flowering dates in Missouri occur between June 10 and July 4.

Occurs in swales of upland prairies, low moist river bottom prairies, and spring-fed, calcareous meadows along small valleys in southern and central Missouri locally north to Ralls and Clinton counties.

Ranges from Nova Scotia to Maine, Ontario to North Dakota, south to New York, Ohio, Indiana, Illinois, Louisiana, and Kansas.

This very showy white-flowered fringed orchid is found most frequently in alkaline moist soils, such as calcareous spring-fed meadows in small valleys of the Ozarks, as in Carter County, or in wet river bottom prairies at the base of limestone bluffs, as in Ralls County.

6. ***Habenaria psychodes*** (L.) Spreng.

Small Purple Fringed Orchid Map 691
Flowers July–August.

Ranges from Newfoundland, Quebec, and Ontario, south to Georgia, Tennessee, Ohio, Indiana, Illinois, and Iowa.

This species is accepted tentatively on the basis of a flowering specimen taken by the author on July 23, 1949, from a plant seen in the wildflower garden of Mr. Bill Bauer. This garden at that time was located in Old Orchard in Webster Groves in St. Louis County, and reputed to have been found by Bauer in the southern Ozarks in Ozark County in the Caney Mountain Refuge along Caney Creek, T23N, R13W, sect. 8, 5½ mi. north of Gainesville. A visit was made with Mr. Bauer the next day, July 24, to this station in order to verify the record and to study the environment of the orchid. A search was made around a wet wooded area bordering a spring and spring branch where Mr. Bauer said the orchid was seen, but a recently fallen tree at this locality had obstructed the site and destroyed all herbaceous ground vegetation. The result was that no evidence could be found for the occurrence of a single plant of this species.

For the record, the collection from Mr. Bauer's garden, *Steyermark* 68585, is the only extant one that may afford a clue to a later rediscovery of this species from the Ozark County locality or another station.

7. ***Habenaria peramoena*** Gray

Purple Fringeless Orchid Map 692
Flowers late June–August. Most of the flowering dates recorded in Missouri are between July 4 and July 24.

Occurs in low wet woods along streams, wooded margins of lakes, rocky moist wooded ground around springs, and less frequently in low swampy meadows along creeks. Known in Missouri only from the southeastern portion of the state north to St. Francois

County and west to Iron, Carter, and Ripley counties
Ranges from New Jersey and Pennsylvania to Ohio, Illinois, and southeast Missouri, south to North Carolina, Alabama, and Tennessee.
This is a handsome orchid with showy rose-purple flowers in a large inflorescence 6–18 cm. long and

4–7 cm. thick.
This and the other species of *Habenaria* do not succeed in wildflower gardens and die out after a year or two. It is hoped that they will be protected, undisturbed, and allowed to perpetuate themselves wherever found.

4. **Pogonia** Juss. Snake-mouth

Pogonia ophioglossoides (L.) Ker
Snake-mouth
Map 693
Flowers early June–July. Flowering dates in Missouri are June 4, July 4–10.
This species was discovered in 1948 by Mr. Bill Bauer from a calcareous swampy meadow fed by a spring in Reynolds County. The data are: swampy meadow bordering spring branch tributary to Middle Fork of Black River, along highway 21, T32N, R1E, sect. 15, 1.8 mi. southwest of bridge over Middle Fork, about 3 mi. northeast of Centerville, July 4, 1948, *Bill Bauer*. It was subsequently collected by the author from the same locality, *Steyermark* 71735

on June 17, 1951. Typical *P. ophioglossoides* var. *ophioglossoides*, which is the one found in Missouri, ranges from Newfoundland west to Ontario, south coastwise to Florida to Texas, inland to Pennsylvania, Tennessee, Indiana, Illinois, Missouri, and Minnesota. Another variety, var. *brachypogon* Fern., with practically no beard on the lip, is found in Nova Scotia.
It is hoped that other stations will eventually be found in Missouri for this rare orchid, as the permanence of the present known station is endangered because of disturbance by hogs and other livestock, even though the swamp has been fenced.

5. **Isotria** Raf. Whorled Pogonia

Flower-stalk (peduncle) shorter than the ovary; fruiting capsule 1.3–2.5 cm. long, its stalk (peduncle) 0.5–2 cm. long; sepals as long as the petals or at most 1½ times the length of the petals, 1.5–2.5 cm. long
2. *I. MEDEOLOIDES*
Flower-stalk (peduncle) longer than the ovary; fruiting capsule 2.5–3.5 cm. long, its stalk (peduncle) 2.5–6 cm. long; sepals 2–3 times as long as the petals, 3.5–6 cm. long 1. *I. VERTICILLATA*

1. **Isotria verticillata** (Willd.) Raf.
Large Whorled Pogonia
Map 694
Flowers May.
Occurs in acid soils of woodland on slopes in deep ravines or on level ground. Known only from southeastern Missouri in Butler (vicinity of Poplar Bluff, August 3, 1897, *Savage & Stull* 1362 in herb. Univ. of Iowa and Chi. Nat. Hist. Museum) and Ste. Genevieve (along Pickle Creek, about ¼ mi. down

valley from Pickle Spring, T36N, R7E, about 6 mi. southeast of Sprott, June 7, 1952, *Steyermark* 73313) counties.
Ranges from Florida to Texas, north to Maine, New York, Ohio, Michigan, and Missouri.
The Ste. Genevieve County record of this very rare and local orchid was first discovered by Mr. Oscar Petersen of St. Louis County. In the pine-oak covered slopes of the ravine where it grows, bluffs and out-

crops of LaMotte sandstone occur, producing a fine sandy acid soil in which these plants prosper. Over a hundred plants of this orchid were seen at this locality, occurring in colonies, and associated with *Rhododendron roseum*, *Vaccinium vacillans*, and other acid-soil plants. Over a period of ten years' observation at this locality, annual variations occurred in the relative abundance of plants; some years the plants were plentiful, other years they were scarce. Some years also witnessed little or no flowering.

The sepals in this species are linear, colored with dull brown-purple above and yellow-green below; the lateral petals are yellow-green, and the lip is green on the main portion with a larger white lobe and smaller white and purple-striped lateral lobes.

2. ***Isotria medeoloides*** (Pursh) Raf.

Small Whorled Pogonia

Map 695

6. ***Triphora*** Nutt. Nodding Pogonia

Triphora trianthophora (Sw.) Rydb.

Nodding Pogonia

Map 696

Pogonia trianthophora (Sw.) BSP. [P & S]

Flowers July 28–October 5.

Rich woods, along slopes, in level ground of valleys along creeks in the Ozarks, and in level ground of rich alluvial forest in the lowlands of southeastern Missouri, sometimes on rotting logs. Southern and central Missouri, north to St. Louis, Boone, and Jackson counties.

Ranges from Florida to Texas, north locally to

Isotria affinis (Aust.) Rydb. [P & S]

Flowers May.

Known only from southeastern Missouri in Bollinger County (wooded limestone hill, near Glen Allen, May, 1897, *Colton Russell*).

Ranges from Maine and Vermont south to North Carolina; and Missouri.

This is considered the most local and the rarest native orchid of the eastern and central United States.

The author has visited the vicinity of Glen Allen several times, as well as other favorable adjacent areas in the county in the hope of rediscovering the station for this species, but he has never met with success. Russell's collection is the only known Missouri record.

The sepals and lateral petals are greenish-yellow, while the lip has a pale green color.

Maine, New York, Ohio, Michigan, Wisconsin, and Iowa.

This delicate orchid has a lavender and green stem about 8–10 cm. tall, but may attain a height of 30 cm., arising from a small tuber which may send out slender tuber-tipped stolons to give rise to new plants, thus developing a small or large colony. The 3 or 4 short ovate leaves are scattered on the stem which bears at its tip usually 2 or 3 flowers. These have pinkish-lavender sepals, pink and white lateral petals, and a white lip marked with 3 green ridges.

7. ***Calopogon*** R. Br. Grass Pink

Calopogon pulchellus (Salisb.) R.Br. var.

pulchellus Grass Pink

Map 697

Calopogon pulchellus (Salisb.) R.Br. [G, BB, P & S]

Flowers late May (May 24)–early July.

Occurs in moist upland prairies, wet calcareous meadows in spring-fed valleys of small creeks, and sometimes in moist open woods. Southern Missouri

north to Reynolds, Shannon, and Henry counties.

Ranges from Florida to Texas, north to Newfoundland, Quebec, Ontario, and Minnesota. A broader-leaved variety, var. *latifolius* (St. John) Fern., with leaves equaling or longer than the short flower-stem, occurs in the Magdalen Islands and Nova Scotia.

8. ***Epipactis*** Sw. Helleborine

Epipactis helleborine (L.) Crantz.

Helleborine

Map 698

Epipactis latifolia (L.) All. [P & S]

Flowers late June–September.

Known only from southwestern Missouri in Jasper

County (moist open ground at foot of north-facing limestone bluff along Turkey Creek, at 'Castle Rock,' 1 mi. NE of Joplin, July 5, 1928, *Palmer 34965*, in herb. Botanical Museum, Harvard University).

Native of Europe; introduced into the United

697 *Calopogon pulchellus* (Grass Pink)698 *Epipactis* Helleborine (Helleborine)

699 *Spiranthes tuberosa* var. *tuberosa* (Little Ladies' Tresses)

This orchid, used for its supposed medicinal value, was introduced into the United States, first having been noted around Syracuse, New York. It often grows in undisturbed woodland habitats, often appearing as if it were a member of the native flora, and prefers a calcareous soil, according to most of the stations where the orchid is known.

The habit of the plant with its broad spreading leaves reminds one of *Smilacina racemosa* which it somewhat resembles superficially. The sepals and lateral petals are green with dull purple, while the lip is similar but darker on the inner side.

9. **Spiranthes** Richard Ladies' Tresses

- a. Flowering late May-mid-June; lip and ovary glabrous (without hairs); lip orange or orange-yellow; axis of inflorescence mainly glabrous or minutely puberulent; leaves present at flowering time, conspicuous at base of plant 6. *S. LUCIDA*
- a. Without the above combination of characters; flowering late July-late November; lip minutely or conspicuously pubescent (with hairs) on the outside; ovary glabrous to pubescent; lip white, or with green or yellow in center; axis of inflorescence pubescent or glabrous; leaves absent or present at flowering time *b*
- b. Flowers or fruits ascending to the tip in 1 spiral or twisted series around the flowering axis. *c*
- c. Axis of inflorescence, ovaries and bracts of flowers glabrous (without hairs); leaves usually absent, dried, or wilted at flowering time, when present all from the base, only 1-5 cm. long, and ovate or elliptic-oblong; lip white or white with a green center; flowers 3-5 mm. long. *d*
- d. Root 1, vertical; lip white; leaves always absent at flowering time 1. *S. TUBEROSA*
- d. Roots 2 or more, spreading; lip with a green center; leaves rarely, but sometimes, present at flowering time 2. *S. GRACILIS*
- c. Axis of inflorescence, ovaries and bracts of flowers hairy (pubescent); leaves present at flowering time, occurring at the base and on the lower part of stem, the larger ones 6-20 cm. long, linear or linear-lanceolate; lip yellow; flowers 6-11 mm. long. 3. *S. VERNALIS*
- b. Flowers or fruits ascending to the tip in 2 or more spiral or twisted series around the flowering axis *e*
- e. Very common, and in open meadows, prairies, and glades; flowers 7-10 mm. long; inflorescence stout, mostly 15-25 mm. across (thick); none of stem-leaves conspicuous at flowering time; root (basal) leaves often absent at flowering time 4. *S. CERNUA*
- e. Very rare, and in low wet or rich woods; flowers 4-5 mm. long; inflorescence slender, mostly 10-14 mm. across (thick); lower stem-leaves conspicuous and well-developed at flowering time; root (basal) leaves usually present at flowering time 5. *S. OVALIS*

I. **Spiranthes tuberosa** var. **tuberosa** Raf.

Little Ladies' Tresses

Map 699

Spiranthes tuberosa Raf. [G, BB in part]

Spiranthes Beckii of auth. [P & S], not Lindl.

Flowers August 21–October.

Occurs in acid soils usually in dry, mossy or rocky (chert, sandstone, or granite) upland oak-hickory or pine-oak woodland, on ridges, crests of hills, leached

700 *Spiranthes gracilis* (Slender Ladies' Tresses)701 *Spiranthes vernalis*702 • *Spiranthes cernua* var. *cernua* (Common Ladies' Tresses)702 □ *Spiranthes cernua* var. *ochroleuca* (Common Ladies' Tresses)

upper slopes above bluffs and escarpments, and sometimes in dry prairie or meadows. Ozark and east-central sections of the state north to Ralls County and west along a line from Callaway, Maries, Laclede, and Greene to Barton County.

Ranges from Georgia to Mississippi, north to New Jersey, Ohio, Indiana, and Missouri.

Another variety, var. *Grayi* (Ames) Fern., occurs from Massachusetts to North Carolina.

This is a very slender and delicate-stemmed species, attaining a height usually of 1.5–2 dm., less frequently taller. The stem just below the inflorescence is usually less than 1 mm. thick.

The length of the perianth is given as 2–3 mm. in the eighth edition of *Gray's Manual*, but Missouri material usually measures 4–4.5 mm.

2. *Spiranthes gracilis* (Bigel.) Beck

Slender Ladies' Tresses

Map 700

Flowers August 20–October.

Occurs in similar situations to those of *S. tuberosa*, in acid soils usually in dry, mossy, or rocky (chert, sandstone, or granite) upland oak-hickory or pine-oak woodland, on ridges, crests of hills, and leached upper slopes above bluffs and escarpments, and less frequently, in upland prairies. Southern and central Missouri, mostly in the Ozark section north to St. Louis, Randolph, and Jackson counties, and locally north in Sullivan County.

Ranges from Florida to Texas, north to Maine, New York, Ohio, Indiana, Wisconsin, Missouri, and Oklahoma.

Like *S. tuberosa*, this is a very slender- and delicate-stemmed species with a stem diameter of usually less

than 1 mm. just below the inflorescence. The stems are somewhat taller than in *S. tuberosa*, varying from usually 2.5–4 dm. tall, less frequently taller.

3. *Spiranthes vernalis* Engelm. & Gray Map 701

Flowers July 11–early September.

Occurs in upland prairies and swampy meadows, usually in acid soils. Infrequent and scattered in southern and central Missouri north to St. Louis, Phelps, Hickory, and Jackson counties.

Ranges from Florida to Texas, north to Massachusetts, New York, Ohio, Tennessee, Missouri, and Kansas.

This species of Ladies' Tresses grows taller than any other Missouri species, usually attaining a height of 5–10 dm. The hairs on the outer surface of the lip are more conspicuous after the flowers are dry, in the fresh condition appearing as numerous papillae or projections.

In one swampy meadow in Howell County this species occurred with *Viola sagittata*, *Rhoxia virginica*, and *Lysimachia lanceolata*, while in a dry section of a large natural prairie in Phelps County it was blooming on August 18 with *Asclepias stenophylla*, *Hieracium longipilum*, *Linum medium* var. *texanum*, *Sabatia angularis*, *Buchnera americana*, and *Silene regia*.

4. *Spiranthes cernua* (L.) Richard Common

Ladies' Tresses, Nodding Ladies' Tresses Map 702

Flowers August 1–November 23.

Occurs on rocky limestone glades, upland dry prairies, wet meadows and thickets. Common in the southern and central sections of the state, known in northern Missouri in Marion, Putnam, and Nodaway

Plate no. 125. 1. *Epipactis Helleborine*, $\times \frac{2}{5}$. 2. *Goodyera pubescens*, $\times \frac{2}{5}$; a. Flower, $\times \frac{2}{5}$; After Gleason, details from Small, The New York Botanical Garden. 3. *Spiranthes cernua*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden. 4. *Spiranthes gracilis*, $\times \frac{2}{5}$; a. Flower $\times \frac{2}{5}$. 5. *Spiranthes lucida*, $\times \frac{2}{5}$. 6. *Spiranthes tuberosa*, $\times \frac{2}{5}$.

PLATE NO. 125

703 *Spiranthes ovalis*704 *Spiranthes lucida*705 *Goodyera pubescens* (Rattlesnake Plantain)

counties; absent from the lowlands of southeastern Missouri.

Missouri material is represented by 2 poorly separated, difficult-to-distinguish varieties:

Bracts, at least the lower ones, shorter than the corolla; flowers white; seeds with 2 or more embryos. 4a. *S. CERNUA* var. *CERNUA*

Bracts longer than the corolla; flowers whitish, greenish, or strawcolored; seeds with 1 embryo

4b. *S. CERNUA* var. *OCHROLEUCA*

4a. ***Spiranthes cernua* var. *cernua*** Map 702

Spiranthes cernua (L.) Richard [G, BB, P & S]

Flowers August 1–November 23.

This is the commoner of the two varieties in Missouri.

Ranges from Florida to Texas, north to Nova Scotia, Ontario, Michigan, Wisconsin, Minnesota, and South Dakota.

The flowers are very fragrant, often reminiscent of vanilla extract flavor as well as that of lily-of-the-valley, but sometimes flowers are not fragrant. This orchid is really the only common one in the state, and sometimes hundreds of them may be counted in a single meadow, prairie, or glade. They are among the last wild flowers to be seen in bloom in late autumn. The usual height is from 1.5–3.5 dm., but taller plants are found up to 6 or more dm. tall.

4b. ***Spiranthes cernua* var. *ochroleuca*** (Rydb.)

Ames

Map 702

Flowers mainly September 17–October 10.

Scattered in southern and east-central Missouri north to Pike, Franklin, and Boone counties.

Range is the same as var. *cernua*, but less common.

This variety is not easily separated from var. *cernua*, into which it intergrades. Apparently the best distinguishing difference between the two varieties is the number of embryos in the seed, a difficult character to use. The variety *ochroleuca* is being maintained as separate, as it has been adopted by various orchid authorities.

5. ***Spiranthes ovalis*** Lindl.

Map 703

Flowers September 12–October 3.

Occurs in low or rich moist woodland. Rare and scattered in the state, where known only from St. Louis and Jackson counties in central Missouri, and Mississippi County in the southeastern lowland section of the state.

Ranges from Florida to Texas, north to Virginia, Kentucky, Indiana, and Missouri.

In the Three States Timber Tract adjacent to Big Oak State Park in Mississippi County, the only locality where the author has seen this rare orchid, it occurred in moist soil of deep tall forest where Bald Cypress (*Taxodium*) and a rich assemblage of other kinds of forest trees abounded.

6. ***Spiranthes lucida*** (H. H. Eat.) Ames Map 704

Flowers late May–mid-June. Flowering dates in Missouri are May 25, May 27, May 29, May 31, June 4.

Occurs usually in alkaline soils in swampy, calcareous, spring-fed meadows, moist places at the base of or along the ledges of limestone or sandstone rocks or small bluffs bordering small creeks. Restricted to the southeastern Ozark section, where known from St. Francois, Reynolds, Dent, Shannon, Oregon, Texas, and Howell counties.

Plate no. 126. 1. *Corallorhiza trifida* var. *verna*, $\times \frac{2}{5}$; a. Flower, front view, $\times \frac{2}{5}$; b. Flower, side view, $\times \frac{2}{5}$. 2. *Corallorhiza wisteriana*, $\times \frac{2}{5}$; a. Flower, side view, $\times \frac{2}{5}$; b. Flower, front view, $\times 7$. 3. *Corallorhiza odontorhiza*, $\times \frac{2}{5}$; a. Flower, side view, $\times 5$. 4. *Malaxis unifolia*, $\times 1$; a. Flower, $\times 20$; Details from Small, The New York Botanical Garden. 5. *Liparis Loeselii*, $\times \frac{2}{5}$; a. Flower, side view, $\times 1\frac{3}{5}$; b. Flower, front view, $\times 1\frac{3}{5}$.

PLATE NO. 126

Ranges from New Brunswick to Ontario and Minnesota, south to North Carolina, Ohio, Michigan, Indiana, Illinois, and Missouri.

This is a low-growing species usually only 0.5–1.5 dm. tall, rarely up to 3 dm. The leaves, which are rich grass-green and shining, measure as much as 15 cm. long and 2.3 cm. wide, are of an oblanceolate or oblong shape, and occur mainly at or near the base of the plant.

10. *Goodyera* R.Br. Rattlesnake Plantain

Goodyera pubescens (Willd.) R.Br.

Rattlesnake Plantain Map 705

Flowers late July–mid-September. Flowers mainly August 15–September 15.

Occurs in acid soils overlying sandstone or chert in pine or pine-oak-hickory woodland, at the bottom of deep ravines or small canyons, and along north-facing wooded slopes of sandstone or chert-covered hills from the base to three-quarters distance up. Rare and scattered in the southern Ozarks, where known only from Ste. Genevieve (*Steyermark* 63863), Iron, Reynolds (*Steyermark* 73115, 76419), and Douglas (*Steyermark* 23638, 85969) counties.

Ranges from Maine and Quebec to Ontario, south to Florida, Alabama, Tennessee, and Missouri.

In a wet springy meadow in Reynolds County where this species was found, it was associated with *Carex leptalea*, *Cardamine bulbosa*, *Castilleja coccinea*, and *Senecio aureus*. Along Plattin Creek in St. Francois County, where it grew in moist places at the base of shallow limestone bluffs, it occurred with *Selaginella apoda*, *Rhynchospora capillacea*, *Juncus Dudleyi*, and other species of calcareous moist places.

This easily recognized orchid with the decorative white-veined, dark green leaves may eventually be found to have a wider distribution in the Ozark region, when most of the hills in the Ozark counties have been thoroughly searched. In the few stations where it is now known, it is found on well-shaded north-facing slopes in acid soils which are mossy-covered and not completely taken over by ground vegetation. *Hepatica nobilis* var. *obtusa* (*americana*), *Cypripedium Calceolus* var. *pubescens*, *Carex digitalis*, *Thelypteris hexagonoptera*, *Liparis liliifolia*, *Rhododendron roseum*, and *Solidago arguta*, are some of the herbaceous species which have been found associated with Rattlesnake Plantain.

11. *Corallorhiza* Chatelain Coral Root

- a. Blooming July–October; sepals and petals of the flower 3–4 mm. long. 3. *C. ODONTORHIZA*
- a. Blooming February–June; sepals and petals of the flower 4.5–8 mm. long. *b*
- b. Common throughout southern and central Missouri; stem purple, brownish, or purple-red; lip not lobed, white dotted pale or dull purple; sepals and petals 6–8 mm. long, greenish-yellow prominently marked with purple-brown or purple 2. *C. WISTERIANA*
- b. Known only from Lawrence County, southwestern Missouri; stem yellowish or greenish-yellow; lip with a shallow lobe on each side at the base, white, not spotted or with very few reddish dots; sepals and petals 4.5–6 mm. long, mostly yellow-green, not spotted 1. *C. TRIFIDA* var. *VERNA*

1. *Corallorhiza trifida* Chatelain var. *verna*

(Nutt.) Fern. Early Coral Root, Pale Coral Root Map 706

Flowers late April–May.

Known only from Lawrence County in southwestern Missouri (rocky woods along creek near Red Oak, May 1, 1925, *Palmer* 26962).

Ranges from Newfoundland to British Columbia, south to Georgia, Tennessee, Ohio, Indiana, Wisconsin, Missouri, South Dakota, Colorado, and Oregon.

Typical *C. trifida* var. *trifida* with red-spotted or brown-tinged perianth, ranges farther north and occurs also in Eurasia.

2. *Corallorhiza wisteriana* Conrad

Coral Root Map 707
Flowers February–June.

Occurs in rich or rocky open woods on slopes, crests of hills, and valley and ravine bottoms. Common in southern and central Missouri north to Pike, Boone, Saline, Lafayette, and Platte counties.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, West Virginia, Ohio, Indiana, Illinois, Missouri, and reported from South Dakota.

Mr. Bill Bauer has grown this species successfully in his wildflower garden, where it spread over a period of several years. He reports the earliest flowering took

706 *Corallorhiza trifida* var. *verna* (Early Coral Root)

707 *Corallorhiza wisteriana* (Coral Root)

708 *Corallorhiza odontorhiza* (Late Coral Root)

place in February. The fruiting capsules are 8–12 mm. long.

3. ***Corallorhiza odontorhiza*** (Willd.) Nutt. f.
odontorhiza Late Coral Root Map 708
Corallorhiza odontorhiza (Willd.) Nutt.
Flowers August–October.
Occurs in wooded rocky or nonrocky areas, on slopes, upland ridges, and in low valleys, often in acid soils. Scattered over the state but less common than *C. wisteriana*.

Ranges from Maine to Minnesota, south to Georgia, Alabama, Mississippi, and Missouri.
The sepals and lateral petals in typical *C. odontorhiza* f. *odontorhiza* are greenish with purple to brown with maroon or dull dark purple, and the lip is white with purple-magenta margins and dots. The small capsules are 5–8 mm. long. In *Corallorhiza odontorhiza* f. *flavida* Wherry the lip is unspotted and the flower-stem, sheaths, sepals, and lateral petals are yellow without purplish markings.

12. ***Malaxis*** Sw. Adder’s Mouth

- Malaxis unifolia*** Michx. f. ***unifolia***
Green Adder’s Mouth Map 709
Malaxis unifolia Michx. [G, BB, P & S]
Flowers May–June.
Occurs in dry rich woodland, on upland slopes or ridges or in ravine bottoms and valley floors bordering streams. In acid or near-neutral soils. Rare and scattered in the Ozark section north to St. Louis and Franklin counties and west to Dent, Greene, and Howell counties.
Ranges from Newfoundland to Saskatchewan,

south to Florida, Louisiana, and Texas.
This diminutive orchid seldom grows over 20 cm. tall, usually varying from 6–15 cm.; some specimens rarely attain over 20 cm. The single oval or broadly elliptical leaf without a stalk about halfway up the flowering stem is characteristic of typical *M. unifolia* f. *unifolia* which cannot be confused with any other orchid in the state. A rare form occurs with two leaves known as f. *bifolia* Mousley; this has not been found in Missouri.

13. ***Liparis*** Richard Twayblade

- a. Plants of dry wooded slopes or rocky ledges, common over the state; flowers mainly brownish-purple, the lip 7–12 mm. long 1. ***L. liliifolia***
a. Plants of wet swampy thickets and wet meadows, known only from Shannon County; flowers yellow-green, the lip 4–5 mm. long 2. ***L. loeselii***
1. ***Liparis liliifolia*** (L.) Richard f. ***liliifolia***
Large Twayblade, Lily Twayblade Map 710
Liparis liliifolia (L.) Richard [G, BB, P & S]
Flowers May–June.
Occurs in acid soils in rocky or nonrocky woods, frequently on leached crests or upper slopes of hills or on sandstone ledges along creeks. Common in the Ozark region and again in the northernmost tiers of counties, but apparently absent from a large area of the state between these two areas.
Ranges from New Hampshire to Minnesota, south to Georgia, Alabama, Tennessee, and Missouri.

PLATE NO. 127

712 *Aplectrum byemale* (Adam-and-Eve)713 *Hexalectris spicata* (Crested Coral Root)714 *Saururus cernuus* (Lizard's-tail)15. **Hexalectris** Raf. Crested Coral Root**Hexalectris spicata** (Walt.) Bernh.

Crested Coral Root

Map 713

Flowers July 15–August 26 (flowering dates in Missouri: July 15, 20, 21, 23, 28, August 7, August 26).

Occurs in dry, usually rocky woods of limestone substrata, along or at the base of bluffs, or sometimes bordering limestone openings of glades near red cedar trees. Restricted to the Ozark section of the state north to St. Louis, Franklin, and Boone counties, west to Camden and McDonald counties, and on Crowley Ridge in Dunklin County.

Ranges from Mexico, and Florida to Arizona,

north to Maryland, West Virginia, Ohio, Indiana, and Missouri.

This summer-flowering orchid has larger flowers than the other saprophytic Coral Root orchid (*Corallorhiza*). The showy lip is white and 3-lobed with orchid-colored or rose-purple stripes; the sepals and lateral petals are yellowish-brown or salmon-brown with brownish-purple stripes and have somewhat recurved or spreading tips. The sepals are slightly longer than the petals. Each of the very short-stalked flowers has an ovate bract at the base of the stalk, similar in color detail to the sepals and lateral petals.

Subclass 2. **DICOTYLEDONEAE**, Dicotyledons

Embryo with usually two cotyledons. Woody (vascular) bundles usually united into a ring surrounding a central pith. Parts of flowers mostly in 4's or 5's, but many other combinations may occur. Leaves mostly with the veins forming a network.

Order **PIPERALES**Fam. **SAURURACEAE** (Lizard's-Tail Family)**Saururus cernuus** L. Lizard's-tail

Map 714

Flowers May–September.

Occurs in swampy woods, borders of sloughs, spring branches, and slow streams. Southern and central Missouri north to Pike, Osage, Cole, Pettis, Henry,

and Barton counties.

Ranges from Florida to Texas, north to Rhode Island, Connecticut, Quebec, Ontario, Michigan, Illinois, Missouri, and Kansas.

Order **SALICALES**Fam. **SALICACEAE** (Willow Family)

Leaves several to many times as long as broad; bud scale 1 to a bud; flowering or fruiting catkins erect, ascending, or spreading, not drooping or very rarely drooping; stamens 1-10 to each flower in the catkin. 1. **SALIX**
 Leaves triangular or ovate, about as broad as long; bud scales several to a bud; flowering or fruiting catkins arching or hanging down; stamens 8-30 or more to each flower in the catkin 2. **POPULUS**

1. **Salix** L. Willow

The species of this genus are difficult to identify unless leaves, both male and female flowers, and fruits are collected. Since the male and female flowers are found on different plants, it is necessary to collect specimens from both types in order to have a complete representation of the species. A tree or shrub first collected in flower should be revisited later for mature leaves and, if possible, fruit. The species often hybridize.

Willow pollen is of only minor importance in hay fever. Although the willows are primarily insect-pollinated, they are also wind-pollinated to some extent.

The following keys are based on (1) leaves and twig characters (Key I and II), and on (2) flowers and fruits (Key III and IV).

I. *Key based mainly on leaf and twig characters*

- a. Leaves green on both sides (those at tips of shoots sometimes covered with silvery-silky hairs) *b*
- b. Buds sticky; petioles with glands just below base of leaf-blade; introduced tree 4. **S. FRAGILIS**
- b. Buds not sticky; petioles without glands; mostly native trees or shrubs *c*
- c. Teeth on margins of leaves remotely and unequally spaced, only 3-12 to an inch (2.5 cm.); leaves with very short stalks (petioles) at most 3 mm. long or nearly stalkless 7. **S. INTERIOR**
- c. Teeth on margins of leaves closely and equally spaced, mostly 13-25 to an inch (2.5 cm.); stalks (petioles) of leaves 4-14 mm. long *d*
- d. Large tree; leaves narrowly lanceolate with conspicuous long tapering tip, 5-10 times as long as broad; branchlets brittle at base; catkins appearing with the leaves 1. **S. NIGRA**
- d. Small or tall shrubs; leaves broader, of oblong-lanceolate to ovate shape, gradually tapering at tip (acuminate), but not conspicuously long-tapering, mostly 3-4 times as long as broad; branchlets not brittle at base; catkins appearing before or with the leaves 8. **S. RIGIDA**
- a. Leaves silvery, gray-white, pale bluish-green, or glaucous (whitish coating) on lower side *e*
- e. Margins of leaves entire (without teeth), shallowly wavy-edged (undulate-crenate), or with only 2-11 broad low teeth to an inch (2.5 cm.) *f*
- f. Lower side of leaf more or less hairy; twigs often hairy; low shrub mainly 0.3-2 m. tall, in prairies, dry open woods, rocky washes, slopes and thickets 11. **S. HUMILIS**
- f. Lower side of leaf glabrous; mature twigs glabrous (without hairs) or nearly so; plants of other kinds of habitats, mostly very wet *g*
- g. Some of the leaves opposite or nearly opposite, thin, purple-tinged; escaped from cultivation 14. **S. PURPUREA**
- g. All the leaves alternate, thick, not purple-tinged; native shrub 10. **S. DISCOLOR**
- e. Margins of leaves finely and distinctly toothed, the teeth more crowded, 12-25 to an inch (2.5 cm.) *h*
- h. Lower side (surface or veins or both) of some or all of the leaves more or less pubescent (with hairs) *i*
- i. Youngest twigs or topmost part of twigs or branchlets hairy *j*
- j. Leaves 5-9 times as long as broad, oblong-lanceolate or narrowly lanceolate; scales (bracts) of catkins yellow to white, falling before the capsule matures; plants of rocky stream beds and gravel bars and rocky banks mainly of the Ozark region of southern and central Missouri 2. **S. CAROLINIANA**
- j. Leaves 2½-5 times as long as broad, oblong-lanceolate or oblanceolate to ovate-oblong; scales (bracts) of catkins mostly brown or darkened at the tip, remaining attached to the catkin until it shrivels; plants mainly of other habitats *k*

- k. Stipules at the base of the leaf-stalk on the younger shoots conspicuous, semi-ovate to nearly circular or somewhat bean-shaped 8. *S. RIGIDA* f. *MOLLIS*
- k. Stipules of younger shoots all small and not conspicuous *l*
 - l. Lower surface of leaves often silky-hairy with hairs pressed against surface; leaves narrowed or tapering at base of blade; capsules or ovaries frequently somewhat silky-hairy; branchlets brittle, breaking easily 8. *S. × MYRICOIDES*
 - l. Lower surface of leaves with soft more or less spreading hairs; leaves more rounded or curved at base of blade; capsules or ovaries glabrous (without hairs); branchlets hard to break 9. *S. ERIOCEPHALA*
- i. Youngest twigs or topmost part of twigs or branchlets glabrous (without hairs) or nearly so . . . *m*
 - m. Stipules conspicuous (0.5–1.5 cm. long) ovate, and mostly persistent on the young or new leafy shoots 2. *S. CAROLINIANA*
 - m. Stipules either none or minute or lanceolate, small and inconspicuous, or not persisting, but soon falling *n*
 - n. Leaves not usually turning black when dried; planted tree, spread from cultivation; capsules or ovary glabrous (without hairs) 6. *S. ALBA*
 - n. Leaves turning black when dried; native shrubs; capsules or ovary finely silky-hairy *o*
 - o. Growing in calcareous swampy meadows, around springs, and spring branches in the eastern Ozark region; teeth occur along margins of leaves from base to tip and teeth not tipped with glands; stipules of young shoots lanceolate, eventually falling; twigs or branchlets easy to break, brittle 13. *S. SERICEA*
 - o. Growing in low ground along streams in northeastern Missouri; teeth do not occur at base of leaf, and teeth which are present are tipped with glands; stipules none or very tiny and quickly disappear; twigs or branchlets hard to break or tear 12. *S. GRACILIS* var. *TEXTORIS*
- h. Lower side of leaves glabrous (without hairs) or mainly so *p*
 - p. Youngest twigs or topmost part of twigs or branchlets hairy 2. *S. CAROLINIANA*
 - p. Youngest twigs or topmost part of twigs glabrous (not hairy) *q*
 - q. Strong leafy sprouts with conspicuous semi-ovate, nearly circular, or somewhat bean-shaped stipules occurring at the base of the leaf-stalks 8. *S. RIGIDA*
 - q. Strong leafy sprouts with no stipules or stipules very tiny and quickly disappearing *r*
 - r. Shrub; scales (bracts) of catkins pale brown to yellow, remaining attached until catkins dry up 12. *S. GRACILIS* var. *TEXTORIS*
 - r. Tree; scales (bracts) of catkins yellow to white, falling before the capsule is mature *s*
 - s. Tiny glands are not present at the summit of the leaf-stalk (petiole); leaf-stalk is twisted; native tree found along the Missouri, Mississippi, and large streams of eastern, central, and northern Missouri 3. *S. AMYGDALOIDES*
 - s. Tiny glands occur at the summit of the leaf-stalk (petiole); leaf-stalk not twisted; planted trees spread from cultivation *t*
 - t. Branchlets of previous year drooping or hanging down 5. *S. BABYLONICA*
 - t. Branchlets not drooping or hanging down *u*
 - u. Branchlets hard to break, tough; leaf-stalk (petiole) of young leaves not sticky; teeth averaging 7–11 per cm. of leaf-margin 6. *S. ALBA*
 - u. Branchlets easily broken, brittle; leaf-stalk (petiole) of young leaves sticky toward the tip; teeth averaging 3–7 per cm. of leaf-margin 4. *S. FRAGILIS*

II. Key based on floral, fruit, vegetative, and habitat characters

- a. Catkins expanding with or after the leaves (see also *S. petiolaris* keyed out in other *a.*); ovary or capsule glabrous (without hairs), or rarely thinly silky in *S. interior* (*S. petiolaris* with pubescent capsules should be keyed in other *a.*) *b*
 - b. Scales of catkins dark brown, remaining attached to catkin and persisting until catkin dries up; filaments in male flowers glabrous; male flowers with 1 basal gland *c*
 - c. Growing along the Missouri and Mississippi and large streams of northern, central, and eastern Missouri; fruiting capsules 7–10 mm. long; style 0.6–1.2 mm. long; main twigs hairy; stipules of strong leafy shoots small and inconspicuous; fruiting catkins 6–10 cm. long 9. *S. ERIOCEPHALA*
 - c. Along streams, spring branches, and wet meadows and thickets throughout Missouri; fruiting

- capsules 4-7 mm. long; style 0.2-0.5 mm. long; main twigs glabrous or hairy; stipules of strong leafy shoots large and conspicuous; fruiting catkins 2.5-6 cm. long 8. *S. RIGIDA*
- b. Scales of catkins yellow to whitish, falling and disappearing before capsule ripens; filaments in male flowers hairy at least at the base; male flowers with 2 basal glands d
- d. Flowers in more or less definite whorls, circles, or tiers from base to tip of catkin; 3-12 stamens to each male flower e
- e. Branchlets or twigs mostly yellowish, tough, hard to break; stipules of strong leafy shoots none or minute; pistillate flowers with 2 glands 3. *S. AMYGDALOIDES*
- e. Older branchlets or twigs mostly red- or purple-brown, brittle at base, easy to break; stipules of strong leafy shoots conspicuous, persistent; pistillate flowers with 1 gland f
- f. Growing along gravel bars and rocky banks of streams mainly in the Ozark section of southern and central Missouri; leaves whitened or silvery on lower surface; branchlets chiefly hairy; stipules broadly ovate 2. *S. CAROLINIANA*
- f. Growing along more muddy sections of streams, sloughs, and ponds and throughout the state; leaves green both sides; branchlets at first hairy, later glabrate; stipules semi-cordate, acute, serrate with glands on tips of teeth 1. *S. NIGRA*
- d. Flowers spirally arranged along the axis of the catkin, not in whorls or tiers; 1-2 stamens to each male flower g
- g. Native shrub or small tree, spreading by underground stems and forming colonies along mud flats and sand bars along streams, sloughs, and ponds; catkins frequently clustered at the tips of crowded branchlets; leaves nearly stalkless, the leaf-stalks (petioles) at most 3 mm. long; 3-12 rather distantly spaced teeth to each inch (2.5 cm.) of leaf-margin 7. *S. INTERIOR*
- g. Planted, introduced large tree, not forming colonies; catkins at the tips of scattered short leafy side branches; leaves with a leaf-stalk (petiole) 5-15 mm. long; 15-25 closely spaced teeth to each inch (2.5 cm.) of leaf-margin h
- h. Young leaf-stalks (petioles) without any glands nor sticky at the summit; female flowers with 1 gland; branchlets tough, not easily broken, hairy or glabrous (without hairs) . 6. *S. ALBA*
- h. Young leaf-stalks (petioles) with glands or sticky at the summit; female flowers with 2 glands; branchlets brittle at base, easily broken, usually quite glabrous i
- i. Branchlets drooping or hanging down; mature leaves 2-12 cm. long, 0.5-2 cm. broad; capsules 1-2 mm. long, almost or quite sessile (without a stalk) 5. *S. BABYLONICA*
- i. Branchlets not drooping nor hanging down; mature leaves 10-15 cm. long, 2.5-4 cm. broad; capsules 4.5-5.5 mm. long, on stalks (pedicels) 0.5-1 mm. long 4. *S. FRAGILIS*
- a. Catkins expanding before the leaves unfold; ovary or capsule hairy j
- j. Leaves nearly opposite on the branchlets; filaments of male flowers united to the summit; male flowers with 2 glands; ovary and capsule in female flowers sessile (without a stalk) . . . 14. *S. PURPUREA*
- j. Leaves alternately arranged on the branchlets; filaments of male flowers free; male flowers with 1 gland; ovary and capsule in female flowers on definite stalks k
- k. Plants known only from extreme northeastern Missouri; fruiting catkins 2-3 cm. thick; female flowers with a definite elongated style 0.5-0.7 mm. long; capsules 7-12 mm. long; stipules of strong leafy shoots large, conspicuous, 1 cm. long, and persistent. 10. *S. DISCOLOR*
- k. Without the above combination of characters; fruiting catkins 0.5-2 cm. thick; female flowers with no style; capsules 3-9 mm. long; stipules of strong leafy or fertile shoots none or minute or lanceolate and quickly falling. l
- l. Low shrub mainly 0.3-2 m. tall, in prairies, dry open woods, rocky washes, slopes, and thickets throughout Missouri; fruiting capsules mainly 7-9 mm. long; male flowers with glabrous filaments; leaves not turning black when dried; twigs and young branchlets mainly gray- or white-hairy covering a pale brown to yellow surface; leaves thickish. 11. *S. HUMILIS*
- l. Shrub mainly 2-4 m. tall, in swamps and wet meadows and wet ground along streams, either in the eastern Ozark section or in northeastern Missouri; fruiting capsules mainly 3-7 mm. (rarely to 9) long; male flowers with filaments glabrous or hairy at base; leaves turning black when dried; twigs and young branchlets mainly glabrous, mainly dark brown or purplish, or also green to olive brown; leaves thinner and more membranaceous m
- m. Plants of swampy meadows, springs, spring branches, and open swamps of the eastern Ozark region; scales of catkins dark brown to black; capsules 2-5 mm. long, broadly rounded above; leaves evenly and finely toothed along margins from base to tip; twigs and branchlets brittle at base, easily broken; stipules of strong leafy shoots lanceolate . 13. *S. SERICEA*

- m. Plants along streams of northeastern Missouri; scales of catkins pale brown to yellow; capsules 5-7 (rarely 9) mm. long, tapering above to a blunt tip; leaves usually without teeth at base; twigs and branchlets tough, hard to break; stipules none or minute 12. *S. GRACILIS* var. *TEXTORIS*

III. Key based principally on male flowers

- a. Two glands at base of each male flower *b*
 b. Stamens 3-12 on each flower *c*
 c. Stipules not present or very small; branchlets yellowish, tough, hard to break . 3. *S. AMYGDALOIDES*
 c. Stipules conspicuous, persisting; branchlets with red or purple, brittle at base, easy to break . . . *d*
 d. Young unfolding leaves green both sides; large trees growing along more muddy sections of streams, sloughs, and ponds throughout the state; branchlets at first hairy, later glabrate 1. *S. NIGRA*
 d. Young unfolding leaves whitened or glaucous beneath; small trees or shrubs growing along gravel bars and rocky banks of streams mainly in the Ozark section of southern and central Missouri; branchlets chiefly hairy 2. *S. CAROLINIANA*
 b. Stamens 1 or 2 on each flower *e*
 e. Stamen 1, the 2 filaments completely united; leaves mostly almost opposite or nearly so . 14. *S. PURPUREA*
 e. Stamens 2, the filaments free and distinct; leaves alternate *f*
 f. Native shrub or small tree, spreading by underground stems and forming colonies along mud flats and sand bars along streams, sloughs, and ponds; catkins frequently clustered at the tips of crowded branchlets; leaves nearly stalkless, the leaf-stalk (petioles) at most 3 mm. long; 3-12 rather distantly spaced teeth to each inch (2.5 cm.) of leaf-margin; filaments densely long-hairy in lower half 7. *S. INTERIOR*
 f. Planted, introduced large tree, not forming colonies; catkins at the tips of scattered short leafy side branches; leaves with a leaf-stalk (petiole) 5-15 mm. long; 15-25 closely spaced teeth to each inch (2.5 cm.) of leaf-margin *g*
 g. Young leaf-stalks (petioles) without any glands nor sticky at the summit; branchlets tough, not easily broken, hairy or glabrous (without hairs) 6. *S. ALBA*
 g. Young leaf-stalks (petioles) with glands or sticky at the summit; branchlets brittle at base, easily broken, usually quite glabrous *h*
 h. Branchlets drooping or hanging down; mature leaves 2-12 cm. long, 0.5-2 cm. broad; staminate catkins 6-8 mm. thick, 1-4 cm. long 5. *S. BABYLONICA*
 h. Branchlets not drooping nor hanging down; mature leaves 10-15 cm. long, 2.5-4 cm. broad; staminate catkins 9-10 mm. thick, 3-5 cm. long 4. *S. FRAGILIS*
 a. One gland at base of each male flower *i*
 i. Filaments hairy at base *j*
 j. Staminate catkins 1.5-2.5 cm. thick; found in extreme northeastern Missouri 10. *S. DISCOLOR*
 j. Staminate catkins 0.5-1.3 cm. thick; found in eastern Ozarks and northeastern Missouri *k*
 k. Staminate catkins 5-8 mm. thick; bracts of catkin blackish; branches dark brown or purple, brittle at base, easy to break; found in swampy meadows and swamps of the eastern Ozarks 13. *S. SERICEA*
 k. Staminate catkins 10-13 mm. thick; bracts of catkin pale brown with black tip; branches yellow, greenish, or reddish-purple, tough, hard to break; found along streams in northeastern Missouri 12. *S. GRACILIS* var. *TEXTORIS*
 i. Filaments mainly glabrous *l*
 l. Catkins opening before unfolding of leaves; low shrubs 0.3-2 m. tall, in prairies, dry open woods, rocky washes and slopes 11. *S. HUMILIS*
 l. Catkins opening together with the unfolding leaves *m*
 m. Main twigs hairy; stipules of strong leafy shoots small and inconspicuous; growing along the Missouri, Mississippi, and larger streams of northern, central, and eastern Missouri 9. *S. ERIOCEPHALA*
 m. Main twigs glabrous or hairy; stipules of strong leafy shoots large and conspicuous; growing along streams, spring branches, wet meadows, and thickets throughout Missouri 8. *S. RIGIDA*

IV. Key based primarily on female flowers

- a. Leaves mostly opposite or nearly so; catkins frequently in 2's at the nodes (joints of axis), 5-6 mm. thick; capsule sessile, 2-3 mm. long 14. *S. PURPUREA*

- a. Without the above combination of characters; leaves alternate; catkins occurring singly along the branches or at the tips of the branchlets *b*
- b. Flowers in more or less definite whorls, circles, or tiers from base to tip of catkin *c*
 - c. Leaves green both sides; branchlets brittle at base 1. *S. NIGRA*
 - c. Leaves whitish or silvery-gray on lower surface *d*
 - d. Petioles 3–7 mm. long; stipules large, persistent; branchlets reddish or purple, brittle at base, hard to break; small trees or shrubs of gravel bars and rocky banks of streams mostly in the Ozark section of southern and central Missouri. 2. *S. CAROLINIANA*
 - d. Petioles 10–30 mm. long; stipules small, quickly falling; large trees along alluvial muddy soils of the Missouri, Mississippi, and large streams of eastern, central, and northern Missouri 3. *S. AMYGDALOIDES*
- b. Flowers and capsules spirally arranged around the axis of the catkin *e*
 - e. Scales of catkin yellow, white, or pale brown, falling before the capsule ripens. *f*
 - f. Native shrub or small tree, spreading by underground stems and forming colonies along mud flats and sand bars along streams, sloughs, and ponds; catkins frequently clustered at the tips of crowded branchlets; leaves nearly stalkless, the leaf-stalks (petioles) at most 3 mm. long; 3–12 rather distantly spaced teeth to each inch (2.5 cm.) of leaf-margin . 7. *S. INTERIOR*
 - f. Planted, introduced large tree, not forming colonies; catkins at the tips of scattered short leafy side branches; leaves with a leaf-stalk (petiole) 5–15 mm. long; 15–25 closely spaced teeth to each inch (2.5 cm.) of leaf-margin *g*
 - g. Young leaf-stalks (petioles) without any glands nor sticky at summit; female flowers with 1 gland; capsule 3–5 mm. long; branchlets tough, not easily broken, hairy or glabrous (without hairs) 6. *S. ALBA*
 - g. Young leaf-stalks (petioles) with glands or sticky at the summit; female flowers with 2 glands; capsule 1–2 mm. long or about 5 mm. long; branchlets brittle at base, easily broken, usually quite glabrous *h*
 - h. Branchlets drooping or hanging down; capsules 1–2 mm. long, almost or quite sessile; mature leaves 2–12 cm. long, 0.5–2 cm. broad 5. *S. BABYLONICA*
 - h. Branchlets not drooping nor hanging down; capsules 4.5–5.5 mm. long, on slender stalks (pedicels) 0.5–1 mm. long; mature leaves 10–15 cm. long, 2.5–4 cm. broad 4. *S. FRAGILIS*
 - e. Scales of catkins dark brown to blackish, remaining attached to catkin until catkin dries up or capsules open *i*
 - i. Capsule, ovary, and flower-stalk glabrous; catkins flowering with or after the leaves unfold *j*
 - j. Main twigs hairy; stipules of strong leafy shoots small and inconspicuous; capsules 7–10 mm. long; fruiting catkins 6–10 cm. long; growing along the Missouri, Mississippi, and large streams of northern, central, and eastern Missouri 9. *S. ERIOCEPHALA*
 - j. Main twigs glabrous or hairy; stipules of strong leafy shoots large and conspicuous; capsules 4–7 mm. long; fruiting catkins 2.5–6 cm. long; growing along streams, spring branches, wet meadows, and thickets throughout Missouri 8. *S. RIGIDA*
 - i. Capsule, ovary, and flower-stalk hairy; catkins flowering before the leaves unfold *k*
 - k. Style definite, elongate, 0.5–0.7 mm. long; capsules 7–12 mm. long; fruiting catkins 2–3 cm. thick; known only from extreme northeastern Missouri 10. *S. DISCOLOR*
 - k. Style not evident; capsules 3–9 mm. long; fruiting catkins 0.5–2 cm. thick *l*
 - l. Low shrub mainly 0.3–2 m. tall, in prairie, dry open woods, rocky washes, slopes, and thickets throughout Missouri; fruiting capsules 7–9 mm. long; twigs and young branchlets mainly gray- or white-hairy covering a pale brown to yellow surface . 11. *S. HUMILIS*
 - l. Shrub mainly 2–4 m. tall, in swamps, wet meadows, and wet ground along streams, either in the eastern Ozark section or in northeastern Missouri; fruiting capsules mainly 3–7 mm. (rarely to 9) long; twigs and young branchlets mainly glabrous, mainly dark brown to purplish, or also green to olive-brown *m*
 - m. Plants of swampy meadows and open swamps of the eastern Ozark region; scales of catkins dark brown to black; capsules 2–5 mm. long, broadly rounded above; branchlets brittle at base, easily broken 13. *S. SERICEA*
 - m. Plants along streams of northeastern Missouri; scales of catkins pale brown to yellow; capsules 5–7 (rarely 9) mm. long, tapering above to a blunt tip; twigs and branchlets tough, hard to break 12. *S. GRACILIS* var. *TEXTORIS*

715 *Salix nigra* (Black Willow)716 • *Salix caroliniana* (Ward's Willow)716 □ *Salix caroliniana* X *Salix nigra*716 x *Salix caroliniana* X *Salix sericea*716 † *Salix caroliniana* X *Salix rigida*717 • *Salix amygdaloides* (Peach-leaved Willow)717 □ *Salix* X *Glaetzelii* (*Salix amygdaloides* X *Salix nigra*)

1. ***Salix nigra* Marsh.** Black Willow Map 715
Flowers April–May.

Occurs along borders of streams, sloughs, and ponds generally in muddy alluvial soils. Common throughout Missouri and doubtless in every county of the state.

Ranges from New Brunswick to North Dakota, south to Florida and Texas.

Along the streams in the Ozark region this willow is found, not on the immediate gravel bed next to the stream occupied by the pioneering Ward's Willow, *Salix caroliniana*, but in the deeper alluvial soils of mud and silt which have been built up in later stages of formation of river banks. This finer deeper silt occurs back of or behind the zone occupied by *Salix caroliniana*. Outside of the Ozark region, Black Willow is found along the muddy margins and flats bordering all the streams.

This is the largest and tallest of any native species of willow in the United States. Used as mattresses along the larger rivers for reinforcing levees and protecting them from washing, it helps control erosion of river banks.

The wood does not warp or splinter, and is used in the manufacture of toys, packing cases, and some kinds of furniture where strength is not an item of importance, since the wood is one of the softest and lightest of all native eastern hardwood trees. Together with other species of willow, the flexible strips of young branches are made into wicker baskets and ornamental pieces. Small amounts of the wood go into pulping for the papermaking business in the United States. The bitter bark of the root has been

used as an ingredient for blood medicines during spring. This is one of the species I have observed beaver using for dam construction.

2. ***Salix caroliniana* Michx.** Ward's Willow

Map 716

Salix longipes Shuttlew. var. *Wardii* (Bebb) Schneider [P & S]

Flowers April–May.

Occurs along gravel bars, sandy gravel beds, and rocky banks of streams throughout the Ozark region of southern and central Missouri and northward to Marion, Shelby, Macon, Putnam, Grundy, Daviess, and Jackson counties.

Ranges from Florida to Texas, north to Maryland, West Virginia, Pennsylvania, Indiana, Illinois, Missouri, and Kansas; also in Cuba.

This attractive willow, with white lower leaf-surfaces, is abundant along all the Ozark streams where it pioneers as one of the first woody species to occupy the outer edges of gravel bars and rocks in the stream. It is one of the species used in the Ozarks for making into wickerwork for baskets, furniture, and ornamental pieces.

This species hybridizes with *S. nigra*, *S. sericea*, and *S. rigida* in Missouri. Presumed crosses have been recorded between *S. caroliniana* and *S. nigra* scattered in southern and central Missouri, between *S. caroliniana* and *S. sericea* from St. Francois County, and between *S. caroliniana* and *S. rigida* from Taney County.

PLATE NO. 128

718 *Salix fragilis* (Crack Willow)719 *Salix babylonica* (Weeping Willow)720 • *Salix alba* var. *alba* (White Willow)
720 □ *Salix alba* var. *calva*
720 x *Salix alba* var. *vitellina*

Flowers April–June.

Occurs along alluvial muddy banks and low woods bordering the Missouri, Mississippi, and other large rivers of northern, central, and eastern Missouri, south of the Missouri River west to Ripley, Wayne, Ste. Genevieve, St. Louis, Osage, Morgan, Johnson, and Jackson counties.

Ranges from Vermont and Quebec to British Columbia, south to Massachusetts, New York, Ohio, Indiana, Illinois, Missouri, the Rocky Mountain states, south to Texas and New Mexico, and Washington.

The slightly drooping branches give this species the most 'weeping' effect of any of the Missouri species, but not as great as the cultivated Weeping Willow (*S. babylonica*), a native of the Old World. The trees attain a height of nearly 70 feet and are of some importance in acting as a natural agent in reinforcing soils and controlling them against washing along the Missouri and Mississippi rivers and their tributaries. In Europe the split younger branches are woven into baskets.

A hybrid between this willow and the Black Willow (*S. nigra*), known as *Salix* × *Glatfelteri* Schneid., occurs in St. Louis County.

4. *Salix fragilis* L. Crack Willow Map 718 Flowers April–June.

Occurs along streams, in swamps, and wet woods. Infrequent in the state, where known from Pike, St. Louis, Wayne, Dekalb, and Atchison counties.

Native of Europe; planted and escaped from cultivation in the United States and Canada, where naturalized from Newfoundland to Ontario, south to Virginia, Kentucky, Illinois, and Missouri.

This willow attains a height of about 80 feet. During early colonial times it and *S. nigra* were used for powdered charcoal as an ingredient of the black gunpowder then popular. Also called Brittle Willow

because of the twigs, which are very brittle at their base.

5. *Salix babylonica* L. Weeping Willow Map 719 Flowers April–May.

Commonly planted as an ornamental tree, but rarely escaped or naturalized in Missouri away from cultivation in wet ground and meadows, as in Dent and Jackson counties.

Native of China and introduced from Europe into the United States. True *S. babylonica* is hardy only in the southern third of the United States. It hybridizes with *S. alba* and *S. fragilis*.

This tree may attain a height of 30 feet. With its long branches which hang nearly to the ground, it is beautiful the year round. In fall the leaves turn to greenish yellow or pale yellow.

This species is commonly confused with other cultivated 'weeping' willows, such as the Golden Weeping Willow (*S. alba* var. *tristis*), Niobe or Wisconsin Weeping Willow (*S. × blanda*), and Thurlow Weeping Willow (*S. × elegantissima*). The four may be distinguished by their branches and leaves. *S. alba* var. *tristis* having yellow or golden branches with the leaves somewhat silky-hairy on the lower surface, and on the upper as well, in younger leaves; *S. babylonica* with mostly olive-brown or red-brown, sometimes yellow, branches and glabrous narrowly lanceolate leaves 8–15 mm. wide; *S. × elegantissima* and *S. × blanda*, similar to *S. babylonica*, but with broader leaves 15–22 mm. wide, the veins of the leaves in *S. × elegantissima* spreading at an angle of more than 45°. The branches of *S. × elegantissima* also are about twice as long as those of *S. × blanda* and the leaves in *S. × blanda* are shining above, those in *S. × elegantissima* not shining above.

6. *Salix alba* L. White Willow Map 720 Flowers April–May.

Often planted as an ornamental tree and sometimes escaped and naturalized in wet ground along streams and ponds.

Native of Europe and introduced into the United States and Canada.

Three of the varieties of *S. alba* which have escaped from cultivation may be distinguished as follows:

- a. Branchlets olive-green to brown, silky-hairy; leaves white-silky hairy on lower surface.
6a. *S. ALBA* var. *ALBA*
- a. Branchlets brown or yellow, becoming glabrous or nearly so (without hairs); leaves becoming glabrous on lower surface. b
b. Branchlets brown 6b. *S. ALBA* var. *CALVA*
G. F. W. Mey.
- b. Branchlets yellow 6c. *S. ALBA* var. *VITELLINA*
(L.) Stoker

All three varieties have sparingly spread from cultivation.

Another variety, the strongly weeping variation of *S. alba*, known as the Golden Weeping Willow, *S. alba* var. *tristis* Gaud., has long bright yellow branches which hang down, much as in *S. babylonica*, *S. × blanda*, and *S. × elegantissima*. The last two are considered to be of hybrid origin between *S. fragilis* and *S. babylonica*. *Salix alba* var. *tristis* is much hardier farther north in the United States and Canada and commonly planted in those regions, but has not been reported as escaped from cultivation in Missouri.

Salix alba, like *S. fragilis*, became introduced in early colonial times in North America, and was used similarly for making into charcoal for gunpowder purposes and for medicine. The medicine was used as a substitute for quinine and for fevers. The bark of this and other large willows, such as *S. fragilis* and *S. nigra*, has been used for tanning purposes, and the wood used in the making of charcoal. This species and *S. fragilis* are commonly planted around farmyards and pastures in Missouri and elsewhere, where it serves as hedges and for posts, while the younger stems are used for fishweirs and whistles.

The leaves turn a pale yellow in autumn.

7. **Salix interior** Rowlee Sandbar Willow
Map 721

Flowers May-June.

Occurs on sand bars, mud flats, and alluvial muddy banks of streams, oxbow lakes and ponds of river bottoms and flood plains throughout Missouri, except absent apparently in the lowlands of the southeastern section.

Two variations occur in the state:

Leaves, especially the youngest, rather permanent-

ly and densely silky-hairy, the older ones mostly 10-14 mm. (-18) wide, and 3-5 cm. (-7) long.

7b. *S. INTERIOR* var. *INTERIOR* f. *WHEELERI*
Leaves, especially the youngest, less densely silky-hairy, the older ones mainly 5-12 mm. (-15 on strong shoots) wide, and 5-14 cm. long

7a. *S. INTERIOR* var. *INTERIOR* f. *INTERIOR*

7a. **Salix interior** var. **interior** f. **interior**
Map 721

Salix interior Rowlee [G, BB, P & S]

This is the commoner form encountered in the state.

Ranges from Quebec to Alaska, south to Virginia, West Virginia, Ohio, Kentucky, Illinois, Arkansas, Louisiana, Texas, and the Great Plains states; mainly absent from New England and Coastal Plain.

7b. **Salix interior** var. **interior** f. **Wheeleri**
(Rowlee) Rouleau Map 721

Salix interior var. *Wheeleri* Rowlee [BB, P & S]

This is known from several counties in the state, and is less commonly collected.

Of similar range to var. *interior* f. *interior*, but more common around the Great Lakes area and sandhills of Nebraska and Wyoming, and North Dakota.

The Sandbar Willow attains a height of about 20 feet and is generally found in dense stands or thickets of rather impenetrable growth. It is associated with Silver Maple (*Acer saccharinum*) and Cottonwood (*Populus deltoides*) on the river flats of the Missouri and Mississippi rivers for stretches of many miles on the alluvial silty soils deposited by these rivers. In such places this willow has pioneered to become established, and these areas are poor botanically with only a small variety of plant life, such as *Aster lateriflorus* or *Carex hyalinolepis*. Sandbar Willow makes a good soil binder on these river soils and prevents much washing and erosion which might otherwise take place.

8. **Salix rigida** Muhl. Map 722
Flowers April-May.

Occurs in wet ground along streams, spring branches, and in wet meadows. Throughout the state, except absent from the lowland section of southeastern Missouri.

The following variations may be distinguished:

- a. Leaf margin with few or no teeth 8c. *S. RIGIDA*
var. *RIGIDA* f. *SUBINTEGRA*
- a. Leaf margin with many teeth scattered from base to tip b
- b. Young twigs and branchlets densely hairy; lower side of leaves, especially the mid-

Salix rigida Muhl. [G, BB in part]; *Salix cordata* Muhl. and auth., not Michx. [P & S]

This is the commonly encountered variation in Missouri.

Ranges from Newfoundland to Ontario, south to North Carolina, Mississippi, Arkansas, and Kansas.

8b. *Salix rigida* var. *rigida* f. *mollis*
(Palmer & Steyermark.) Fern. Map 722
Salix cordata f. *mollis* Palmer & Steyermark.
Scattered throughout the state.

8c. *Salix rigida* var. *rigida* f. *subintegra*
(Palmer & Steyermark.) Steyermark. Map 722

Salix cordata f. *subintegra* Palmer & Steyermark. in Ann. Mo. Bot. Gard. 25: 770. 1938.

Known only from Iron and Phelps (shore of lake at Yancy Mills Spring, November 28, 1936, Steyermark 20910, holotype in Missouri Botanical Garden Herbarium) counties.

8d. *Salix rigida* var. *angustata* (Pursh) Fern.

Map 722

Salix cordata var. *angustata* (Pursh) Anderss.
[P & S]

Mainly found in northern and west-central Missouri, and south locally in Wayne and Howell counties.

Ranges from Quebec to Ontario, south to Georgia, Alabama, and Missouri.

Salix rigida hybridizes with several other species of willow. Those which are known in Missouri are hybrids between *S. rigida* and *S. nigra* from Atchison Co.; *S. rigida* and *S. caroliniana* from Taney Co.; *S. rigida* X *S. humilis* from Putnam Co.; and *S. X myricoides* (*S. rigida* X *S. sericea*) from St. Louis, Ste. Genevieve, Cape Girardeau, and Dent counties.

9. *Salix eriocephala* Michx. Map 723

Salix missouriensis Bebb [P & S]

Salix rigida var. *vestita* Anderss. [BB]

Flowers March–April.

Occurs in alluvial soils of silt and mud following the Missouri and Mississippi and other large rivers of northern, central, and eastern Missouri, mainly north of the Missouri River, and south locally to Cape Girardeau and Bates counties.

Plate no. 129. 1. *Salix alba*, X 2/7; a. Female inflorescence, X 2/7. 2. *Salix rigida* var. *rigida*, X 2/7; a. Male inflorescence, X 2/7; b. *Salix rigida* var. *angustata*, X 2/7. 3. *Salix interior*, X 2/7; a. Male flower-branch; b. Female flower-branch. 4. *Salix eriocephala*, X 2/7; a. PLATE NO. 129

724 *Salix discolor* var. *discolor* (Pussy Willow)

724 x *Salix humilis* var. *humilis*
 725 • *Salix humilis* var. *hypophrysa*
 725 □ *Salix humilis* var. *microphylla*
 725 † *Salix humilis* X *Salix eriocephala*

726 *Salix gracilis* var. *textoris*

Ranges from Indiana to Minnesota and South Dakota, south to Kentucky, Missouri, and Nebraska.

This species may become a large tree up to 50 ft. tall. The stipules are smaller and less conspicuous than in *S. rigida*, but the fruiting catkins, capsules, and styles are longer, the leaves are often broader, and the branchlets and lower leaf surface much more pubescent than in *S. rigida*. By some botanists *S. eriocephala* is sometimes combined with *S. rigida* or treated as only a variety of that species, but it seems amply distinct and recognizable from that species, not only on the basis of the characters mentioned above, but also on the habit and habitat; in Missouri *S. eriocephala* is usually a medium- to large-sized tree along the larger streams, whereas *S. rigida* is usually a shrub found along smaller streams and wet meadows. The catkins of *S. eriocephala* also tend to open somewhat earlier than the unfolding leaves, whereas in *S. rigida* they open as the leaves unfold.

A hybrid between *S. eriocephala* and *S. humilis* has been recorded from Jackson County.

As in *S. amygdaloides* and *S. interior*, this species plays an important role in holding back the soil along the river banks and preventing soil erosion. Also the wood, because of its relative permanence when contacting the soil, is used for fence posts.

10. *Salix discolor* Muhl. var. *discolor*

Pussy Willow

Salix discolor Muhl. [G, BB, P & S]

Flowers February–April.

Map 724

Known only from Clark County, northeastern Missouri (August 30, 1892, *Bush*, from World's Fair specimen 2388 in University of Missouri Herbarium). In a letter dated October 21, 1934, *Bush* wrote the author that this specimen was collected 'just north of Dumas on the river bank some 3–4 mi. north of the town.'

Ranges from Labrador to Alberta, south to Maryland, Kentucky, Missouri, South Dakota, and Montana.

The branchlets are glabrous or, if at first hairy, eventually become glabrous in this variety of *S. discolor*, whereas in var. *latifolia* they are more permanently pubescent, as are the bud-scales.

The soft silky hairs clothing the bracts of the catkins give this species much more of a 'Pussy Willow' effect than in most of the other native species, except possibly *S. sericea* and *S. humilis*. The 'Pussy Willow' sold in florists' shops in early spring and planted as an ornamental shrub or small tree is a species from Europe and Asia, known as Goat Willow, *S. caprea* L. It has much larger fuzzy catkins than *S. discolor*, but only sparingly escapes from cultivation, and thus far has not been recorded as an escape in Missouri.

11. *Salix humilis* Marsh. Prairie Willow

Map 725

Flowers March–May.

Occurs in prairies, open woods, rocky draws or washes, rocky slopes, and thickets.

Missouri material is represented by three variations:

- a. Staminate catkins 7–8 mm. thick, 5–12 mm. long; fruiting catkins 10–25 mm. long; leaves 5–15 mm. (up to 17) broad, mostly 15–50 mm. (up to 70) long, nearly sessile (without a stalk) to very short-stalked; shrub 2.5–10 dm. tall 11c. *S. HUMILIS* var. *MICROPHYLLA*
- a. Staminate catkins 10–23 mm. thick, 10–30 mm. long; fruiting catkins 20–50 mm. (up to 80) long; leaves 7–30 mm. broad, mostly 50–100 mm. (rarely 40) long, short-stalked; shrub 10–30 dm. tall b
- b. Lower side of leaves definitely covered with hairs 11a. *S. HUMILIS* var. *HUMILIS*
- b. Lower side of leaves only slightly hairy or

becoming glabrous (without hairs) or nearly so . . . 11b. *S. HUMILIS* var. *HYPORHYSA*

11a. ***Salix humilis* var. *humilis*** Map 725

This is scattered over the state, but is less common than var. *hyporhyssa*.

Ranges from Quebec to Minnesota, south to North Carolina, Kentucky, Louisiana, and Kansas.

Some hairy-leaved Missouri specimens have been referred to var. *keweenawensis* Farw. in Gleason's *New Illustrated Flora* (vol. 2: 22. 1952), but are placed in the present treatment under var. *humilis*.

11b. ***Salix humilis* var. *hyporhyssa*** Fern.

Map 725

Salix humilis var. *rigidiuscula* of auth. [BB, P & S], not Anders.

Throughout Missouri. This is the commonest variation in the state.

Ranges from Florida to Texas, north near the Coastal Plain to Connecticut and Pennsylvania, inland north to West Virginia, Ohio, Michigan, Wisconsin, Iowa, and Oklahoma.

11c. ***Salix humilis* var. *microphylla*** (Anders.)

Fern. Dwarf Gray Willow Map 725

Salix tristis Ait. [BB, P & S]

Scattered in portions of northern and central Missouri, south to Washington, Dent, and Phelps counties.

Ranges from Maine to Minnesota, south to Florida, Mississippi, Louisiana, and Oklahoma.

Although var. *microphylla* is treated by some botanists as a distinct species, it seems better regarded as a dwarf variety of *S. humilis*, smaller in all respects but intergrading with the other varieties of that species.

Salix humilis and varieties can be readily recognized in the field generally by its low growing habit and dry open habitat in prairies, rocky open woods, and similar situations quite in contrast to the wet swampy habitats selected in general by the other species of willow in Missouri.

Presumed hybrid plants have been recorded between this species and *S. rigida* from Putnam County, and between *S. humilis* and *S. eriocephala* from Jackson County.

12. ***Salix gracilis*** Anders. var. ***textoris*** Fern.

Map 726

Salix petiolaris of some auth. [P & S, BB], not Sm. Flowers April–June.

Known only from low wet ground in mud or sandy

gravel along streams in northeastern Missouri, from Clark (*Davis 1500*), Marion, Ralls (*Steyermark 25769*), and Pike counties.

Ranges from Quebec to Manitoba, south to New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Iowa, Missouri, and Nebraska.

This is a low growing shrub, similar in this respect to *S. humilis* and varieties, but with green to olive-brown, slender flexible branches. The narrow leaves, linear to narrowly lanceolate, are entire or have short teeth, and are 2.5–10 cm. long by 3–20 mm. wide.

13. ***Salix sericea*** Marsh. Silky Willow Map 727

Flowers March–May.

Occurs in usually calcareous swampy meadows, swampy ground around springs, and spring branches. Eastern Ozark region north to St. Louis, Washington, and Crawford counties, and west to Texas County.

Two variations are encountered in Missouri:

Lower surface of mature leaves silky-hairy . . .

13a. *S. SERICEA* f. *SERICEA*

Lower surface of mature leaves glabrous (without hairs) 13b. *S. SERICEA* f. *GLABRA*

13a. ***Salix sericea* f. *sericea***

Map 727

This is the common variation encountered.

Ranges from Quebec to Wisconsin and Iowa, south to South Carolina, Tennessee, and Missouri.

13b. ***Salix sericea* f. *glabra*** Palmer & Steyermark

Map 727

Known only from Dent (north prong of Meramec River, between Stone Hill and Indian Trail State Park, August 4, 1936, *Steyermark 12548*, holotype in herbarium of Missouri Botanical Garden) and Reynolds (along Brushy Creek, 1 mi. north of Moses Store, August 13, 1936, *Steyermark 12918*) counties in the central-eastern Ozarks.

Salix sericea is very distinctive in the field, growing as a densely rounded shrub 2–3 meters tall with dark brown to purplish-brown slender twigs and narrowly lanceolate, finely and regularly toothed leaves, which are dark green on upper surface and gray-silvery on lower surface with a fine silky hairiness of appressed hairs. In the calcareous, swampy, spring-fed meadows of the Ozarks it is associated with many herbaceous species of a more northern geographical range, whose presence in the southeastern Ozark area indicates a survival of a relict type left over from and related to a time of prehistoric Pleistocene ice advances.

14. ***Salix purpurea*** L. Basket Willow Map 728

Also called Purple Osier.

Flowers April-May.

Known only from Ralls County, northeastern Missouri (Oakwood, September 17, 1912, *Davis 364*; Oakwood, May 12, 1913, *Davis 250*).

Native of Europe; introduced into the United States and Canada, where ranging from Newfoundland to Ontario and Wisconsin, south to Virginia, West Virginia, Ohio, Illinois, and Missouri.

Several other specimens from Missouri have been misidentified as this species, but pertain elsewhere.

Salix purpurea was brought to this country from Europe in early colonial times and grown for basket-making. The leaves are often purple-tinged and covered with a silvery or gray color; they are entire or finely toothed.

2. *Populus* L. Poplar, Aspen

This genus of trees has wind-pollinated flowers. The pollen is very light and is easily carried by the wind, thus making the poplars eligible for hay fever consideration. While some of the species in the southern and western states are of some importance, those in the central and eastern United States seem to have little importance in hay fever cases.

Instances are reported where the bitter bast substance of the bark has been dried and ground into a flour as an emergency food. The same use has been reported for willows.

I. Key based mainly on leaves and twigs

- a. Young twigs and lower surface of fully grown leaves covered with a white felt of hairs; at least the leaves at end of branches maple-like with 3-5 lobes 1. *P. ALBA*
- a. Twigs at maturity not covered with a white felt of hairs (some white hairiness may be present on young twigs in the beginning stages of growth); fully grown leaves not covered with a white felt of hairs, not 3-5-lobed *b*
- b. Leaves coarsely toothed with large or broad teeth, these usually less than 15 on each edge *c*
- c. Teeth of leaves somewhat triangular and short-pointed; mature leaf-blades mainly 6-12 cm. (rarely 4) long, 4-9 cm. broad, eventually glabrous (without hairs) or nearly so; at least the topmost bud hairy 2. *P. GRANDIDENTATA*
- c. Teeth of leaves mostly blunt or rounded at their tips; mature leaf-blades averaging smaller, mainly 2-6 cm. long, 2-4 (-7) cm. broad, densely hairy to nearly glabrous; buds not hairy 3. *P. TREMULA*
- b. Leaves with closely spaced teeth, these usually 15-50 or more on each edge (rarely less than 15) *d*
- d. Pith of stems orange; tip of leaf usually blunt or round (rarely short-pointed); base of leaf usually heart-shaped or prominently rounded with no space between the rounded portions (sinus deep and closed); leaf-stalks (petioles) terete (rounded in cross section); trees of the swamps of southeastern Missouri 5. *P. HETEROPHYLLA*
- d. Pith of stems white; tip of leaf short- to long-pointed; base of leaf tapering or narrowed or rather straight-edged, if rounded, at least with an open space (sinus) between the rounded

- portions; leaf-stalks (petioles) flattened or compressed toward the summit; trees of other habitats or in other parts of Missouri e
- c. Leaves whitened, definitely paler, and somewhat hairy on lower side; leaf-stalks (petioles) terete or nearly so (rounded in cross section) in upper part 6. *P. × GILEADENSIS*
- e. Leaves usually equally green on both sides, but if pale or grayish on the lower side, then not hairy; leaf-stalks (petioles) flattened laterally (from the sides) in upper part toward leaf-blade f
- f. Teeth along edge (margin) of leaves rather blunt or rounded at tip; leaves usually broadest near the middle or above the base, often as long as broad or longer than broad, as well as shorter than broad, broadly ovate or somewhat round in shape, mostly less than 7 cm. wide; margin of leaves without a thinner translucent border (not permitting light to pass through); trees of northern Missouri only 4. *P. TREMULOIDES*
- f. Teeth along edge (margin) of leaves ending in a more prominent or narrowed or curved point; leaves usually broadest at the very base and usually much broader than long (rarely longer than broad), usually more broadly triangular (deltoid) or somewhat rhombic (somewhat broadly baseball-diamond-shaped), mostly more than 7 cm. broad; margin of leaves with a thin translucent border (permitting light to pass through); trees found in all parts of Missouri g
- g. Tree with a narrow, erect, slender, columnar shape, the branches all conspicuously ascending or erect; no glands at base of leaf-blade; no tiny hairs on edges of leaf-blade. 7. *P. NIGRA* var. *ITALICA*
- g. Trees with more widely spreading branches and a more open crown, not narrow and slender-looking; glands usually present at base of leaf-blade (sometimes absent in *P. × canadensis*); tiny hairs present on edges of leaf-blade h
- h. Common native tree along streams and in low ground; tree with a broad open crown and spreading branches; leaves broadly triangular, usually as broad as long, the base mostly straight-edged (truncate) or somewhat heart-shaped; margins of leaves with numerous hairs; glands 2-4, always present at base of leaf-blade at junction with leaf-stalk 9. *P. DELTOIDES*
- h. Planted tree, sometimes escaping from cultivation and becoming naturalized; tree with a narrower crown, the branches more ascending; leaves triangular-ovate, the base more curved, narrowed, or cuneate; margins of leaves with fewer and more scattered hairs; glands 1-2, either present or often absent at base of leaf-blade. 8. *P. × CANADENSIS*

II. Key based on male and female flowers, fruit, and vegetative characters

- a. Scales of catkins either with short triangular teeth on margin or with 3-7 narrowly triangular or linear-lanceolate, deeply cut lobes or segments, these with long hairs at their tips; stigmas thread-like, terete; stamens 6-12 to each flower of the male catkin; topmost overwintering buds 3-10 mm. long b
- b. Scales of the male and female flowers with short teeth, not deeply cut; young twigs covered with a white hairy felt; topmost bud covered with fine soft downy hairs; mature leaves white-hairy on lower side 1. *P. ALBA*
- b. Scales of the male and female flowers with 3-7 narrowly triangular or linear-lanceolate deeply cut lobes or segments; twigs and winter-buds glabrous or hairy, but not soft white-downy; mature leaves eventually glabrous, young leaves glabrous or white-velvety on lower side. c
- c. Winter buds hairy; branches somewhat gray-hairy at first; unfolding leaves thick and with white-velvety hairs 2. *P. GRANDIDENTATA*
- c. Winter buds glabrous; young branches glabrous or nearly so; unfolding leaves thin and glabrous or soon becoming so d
- d. Leaves irregularly wavy-toothed with the coarse teeth usually less than 12 along either half; tip of leaf-blade usually blunt 3. *P. TREMULA*
- d. Leaves finely and regularly toothed with the small teeth mainly 15-40 along either half; tip of leaf-blade usually short-pointed 4. *P. TREMULOIDES*
- a. Scales of catkins fringed with 9 to many hair-like segments, these without any hairs; stigmas with broadly expanded or dilated lobes; stamens mainly 12-60 to each flower of the male catkin; topmost overwintering bud 10-25 mm. long e
- e. Pith orange; topmost bud on the branch not sticky (viscid); stigmas raised up on a definite slender

730 *Populus grandidentata* (Large-toothed Aspen)731 *Populus tremula* (European Aspen)732 *Populus tremuloides* var. *tremuloides* f. *tremuloides* (Trembling Aspen)

style; unfolding leaves with a white-hairy felt; trees of swamps of the southeastern Missouri lowlands

- e. Pith white; topmost bud on the branch sticky (viscid); stigmas sessile (with a stalk) or nearly so; unfolding leaves without a white-hairy felt; trees of other habitats or in other parts of Missouri *f*
- f. Stigmas 3-4; stamens 40-60; common native tree along streams and in low ground throughout Missouri 9. *P. DELTOIDES*
- f. Stigmas 2; stamens 12-30; planted trees rarely escaping from cultivation and becoming naturalized. *g*
- g. Branchlets or twigs hairy; young leaves white on lower surface, hairy, the base heart-shaped. 6. *P. × GILEADENSIS*
- g. Branchlets or twigs glabrous (without hairs); young leaves glabrous, or if somewhat hairy, the base truncate (as if cut straight across or straight-edged) or curved, narrowed, or cuneate, rarely slightly heart-shaped. *h*
- h. Tree with a narrow, erect, slender, columnar shape, the branches all conspicuously ascending or erect; no glands at base of leaf-blade; no tiny hairs on edges of leaf-blades. 7. *P. NIGRA* var. *ITALICA*
- h. Tree with a more elliptical or narrowly ovate shape, the branches ascending but the crown more open; glands either 1-2 at the base of the leaf-blade at its junction with the leaf-stalk (petiole) or no glands present; scattered hairs occur on edges of leaf-blades. 8. *P. × CANADENSIS*

1. ***Populus alba* L.** Silver Poplar

Also called White Poplar.

Map 729

Flowers March-May.

At one time commonly planted and now well established along streams, fence rows, and roadsides. Found throughout the state, and probably naturalized in every county.

Native of Europe.

This species spreads by underground suckers, forming thickets, and apparently can grow in most kinds of soils and varied situations. It is not commonly planted now as formerly.

2. ***Populus grandidentata* Michx.**

Large-toothed Aspen

Map 730

Flowers March-May.

Known only from Clark County in northeastern Missouri (August 30, 1892, *Bush*, world's fair specimen 2401 in University of Missouri Herbarium).

Ranges from Quebec to Ontario and Minnesota, south to North Carolina, Tennessee, and Iowa; introduced in northeast Missouri.

According to correspondence with *Bush* (letters of September 15, 1933, and October 21, 1934), he stated that he collected this specimen 'just east of the depot. . . [at Dumas]. . . in a field on edge of woods and I decided years ago that the trees were adventive there' and 'escaped from cultivation.' On the basis of *Bush's* letters and since no trees other than these have been seen in Missouri, I am treating the species as introduced in the state.

In the fall the foliage turns to pale yellow. The

Plate no. 130. 1. *Salix humilis* var. *microphylla*, $\times \frac{2}{7}$; a. Female flower-branch, $\times \frac{2}{7}$; b. PLATE NO. 130

wood is used for pulp in papermaking. The sapwood is white, and the heartwood a pale brown. Some radio cabinets and bedroom furniture are occasionally made from a fancy grain which rarely appears in the wood of this species.

3. **Populus tremula** L. European Aspen

Map 731

Flowers March–May.

Known only from Washington County in the eastern Ozark section (near Palmer, T36N, R1W, sect. 13, August 18, 1936, *Steyermark 12997*).

Native of Europe, Asia, and North Africa.

The trees were plentiful where this specimen was found and were well established at this station, where they have escaped from cultivation.

The wood of this species is used for pulp in papermaking.

4. **Populus tremuloides** Michx. var. **tremuloides**
f. **tremuloides** Trembling Aspen

Map 732

Also called Quaking Aspen.

Flowers March–April.

Occurs in thickets and borders of upland woods. Known only from northern Missouri in Clark, Adair, and Sullivan counties; also in Dent County, but not now extant at the Dent County station.

Ranges from Labrador to Alaska, south to Virginia, Tennessee, Missouri, Alberta, New Mexico, and Lower California.

In 1941 the author collected this species in Clark Co. (from upland clay till slopes, 2½ miles southwest of Athens, T67N, R7W, sect. 26, *Steyermark 28640*), where a half dozen large trees were growing in a semi-grazed area. It has also been reported as having been seen in the same county northeast of St. Patricks by Mr. Frederick Dunlap. The species is quite rare in the state and no collections more recent than the above date are known. Bush in a letter of September 15, 1933, writes that '*Populus tremuloides* occurs clear across the state in the northern counties,' but there are no herbarium specimens to support this statement. It is quite probable after still more intensive botanical exploration has been carried out in the northern section of Missouri, that new stations for this species will turn up.

This species was found by Frederick Dunlap, at one time state forester, in Dent County, situated in the Ozarks (along old road to Rolla ¼ mi. west of Salem, March 30, 1934 [flowers] and June 16, 1933 [leaves]), but the trees died in the summer of 1934. A clump of ten stems occurred at this place in a slight depression on the south side of the old road leading

west from Salem toward Rolla and about ¼ mi. from the railroad crossing. Dunlap reported (in letter of December 31, 1936 to Dr. W. J. Robbins in the University of Missouri Herbarium) that this 'location was rather low and inclined to be wet, being in the head of a small valley, and not the sort of place where one would plant trees or build a house. Moreover, it is, as Bush says, not a tree which is planted. I am of the opinion its occurrence is natural. In his list of trees of Greene County, Professor Shepard included this species from that county, but in reviewing his list, Bush states "certainly not native in Greene County. I have never seen this in cultivation anywhere. Nurserymen often call *P. alba* 'Aspen' and 'American aspen,' and I suspect Shepard must have mistaken this for *P. tremuloides*." A number of other species of trees in Shepard's list were based upon misidentifications, and Mr. Dunlap's observations are undoubtedly correct (Bush, *Am. Midl. Nat.* 15: 581–85. 1934; Shepard, E. M. *A List of the Native Trees of the [Greene] County. Mo. Geol. Surv.* 12: 46–47. 1898).

Populus tremuloides is one of the most naturally widely distributed species of trees in North America. It germinates well in fire-scarred areas, rapidly building up a forest on burnt over soil. The foliage of this aspen assumes a pale yellow color in autumn. It is the species chiefly used in North America for pulpwood in papermaking.

5. **Populus heterophylla** L.

Swamp Cottonwood

Map 733

Flowers March–April.

Occurs in inundated wooded swamps throughout the lowlands of southeastern Missouri north to Cape Girardeau and Bollinger counties and west to Wayne and Ripley counties.

Ranges from Florida to Louisiana, north near the Coastal Plain to Connecticut and Pennsylvania, and inland north to Ohio, Michigan, Illinois, and Missouri.

At first the branchlets are white-hairy, later become glabrous. The winter buds have some hairiness at their base. The large leaves are white-hairy at first, but later become glabrous.

The wood is used for pulp in papermaking, and for crates and wooden boxes. It also has been used for interior finish. Nearly half of excelsior material is derived from this species.

6. **Populus × gileadensis** Rouleau

Balm-of-Gilead

Map 734

Populus balsamifera × *P. deltoides* var. *missouriensis*

Populus candicans [of BB, *Steyermark.*], not Ait.

733 *Populus heterophylla* (Swamp Cottonwood)

734 *Populus X gileadensis* (Balm-of-Gilead)

735 *Populus nigra* var. *italica* (Lombardy Poplar)

Flowers March–April.

Known only from a tree escaped from cultivation in Taney County, southwestern Missouri.

Escaped and spread from cultivation from Newfoundland to Ontario, southward.

The origin of this tree is doubtful. Whether it is of hybrid origin between *P. balsamifera* and *P. deltoides* var. *missouriensis* or represents a sterile clone of *P. balsamifera* var. *subcordata*, reproducing by sprouts, remains doubtful. The name used here designates its status as of hybrid origin.

7. ***Populus nigra* L. var. *italica* Muenchh.**

Lombardy Poplar

Map 735

Flowers March–May.

Commonly cultivated throughout Missouri, but rarely escaped and naturalized, as far as known, only in Jasper County, southwestern Missouri (open ground, border of woods, 4 mi. northwest of Webb City, September 27, 1952, *Palmer 55194*).

This tree is known as a staminate tree only and is believed to have originated as a freak or sport from typical *P. nigra* var. *nigra* in Italy, and since propagated through cuttings. As the trees are subject to a canker disease and are short-lived, they are recommended for planting only as a quick-growing hedge or screen for temporary purposes.

8. ***Populus* × *eugenei* Simon-Louis**

Eugene Poplar

Map 736

Also called Carolina Poplar.

Populus deltoides × *Populus nigra* var. *italica*

Populus canadensis var. *eugenei* (Simon-Louis) Schelle [P & S]

Formerly this tree was widely planted, but has rarely escaped from cultivation in Missouri, where it is known to have become established only in Jasper County (open alluvial ground, about old mines, valley of Center Creek, 1 mi. south of Oronogo, October 18, 1953, *Palmer 57074*), southwestern Missouri.

Although extensively planted in the past, this cottonwood, like other cultivated species of *Populus*, is now no longer recommended by nurserymen, and is prohibited by law in some sections of the United States, because of the widely spreading roots which clog up drains and water pipe systems or lift sidewalks and streets. Also, like other species of poplar, it has weak wood, the twigs and limbs breaking away to litter the streets.

This tree is believed to be of hybrid origin between *P. deltoides* and *P. nigra* and possibly includes various hybrid clones which have originated in different places.

It is similar to *P. deltoides*, but the tree has a more upright growth with the branches more ascending. It is sometimes separated as a variety from *P. × canadensis* Moench, a hybrid between *P. deltoides* and *nigra*, by its more pyramidal habit of growth and shorter staminate catkins, but by other authors is placed under the synonymy of *P. × canadensis* (Little, *Check List of Trees of the U.S.*, p. 281. 1953).

9. ***Populus deltoides* Marsh.** Cottonwood

Map 737

Flowers March–May.

Occurs in alluvial soils along streams and in low wet ground. Throughout the state, and doubtless occurring in every county.

Ranges from Quebec to Manitoba, south to Florida and Texas.

Missouri material is represented by the following variations:

- a. Leaf-stalks somewhat hairy when young; veins of lower side of leaf-blade somewhat hairy until late in season. gb. *P. DELTOIDES* var. *DELTOIDES* f. *PILOSA*
- a. Leaf-stalks and leaf-blades usually glabrous (without hairs) from the beginning or soon becoming so b

Map 737

Populus deltoides Marsh. [G, BB, P & S]

This is the widely distributed and common type found throughout the state.

gb. ***Populus deltoides* var. *deltoides* f. *pilosa***

(Sarg.) Sudw.

Map 737

Populus deltoides f. *pilosa* (Sarg.) Sudw. [P & S]

Known only from Dunklin and Reynolds (in back of gravel bar along Middle Fork of Black River, just west of Lesterville, May 21, 1939, *Steyermark* 26530) counties.

gc. ***Populus deltoides* var. *missouriensis*** (Henry)

Rehd. Southern Cottonwood

Map 737

Known from St. Louis (Bridgeton, *Fritchey*), Ripley (southwest of Grandin, *Steyermark* 11826), Wayne (2½ mi. south of Shook, T 27 N, R 7 E, sect. 8, *Steyermark* 6566; Sam Baker State Park, *Steyermark* 1874), and Pulaski (2 mi. southeast of Hazel Run, *Steyermark* 25094) counties.

More frequent southward in the range of *P. deltoides*, especially from Vermont to Ohio and Missouri, south to Florida and Mississippi.

The foliage of the cottonwood at first turns greenish yellow and eventually a dull yellow color. They are rapid-growing but short-lived trees, attaining heights of 150 feet and living only 75–100 years. The leaves may be as small as 4 cm. long by 4 cm. broad, but usually are much larger.

The wood is of very light weight and used in pulp for papermaking. Formerly cottonwood was much employed for making into packing boxes and crates of all sizes, excelsior, posts, and barrel staves. The thick bark was reported to be used by children of early pioneer families for whittling out toys.

Excluded species

***Populus Sargentii* Dode** Great Plains Cottonwood

This species was reported as extending into Missouri in Rydberg's *Flora of the Prairies and Plains*, p. 247. 1932. The report may have been based upon a specimen collected in Jackson County, western Missouri (bottoms, Courtney, June 25, 1915), but this specimen has glabrous bud scales and the leaves are toothed as in typical *P. deltoides*, to which species the specimen is referred in the present flora. No other records are extant to support evidence of its occurrence in the state, but as it is known as far east as Oklahoma, Kansas, and Nebraska, it should be looked for in westernmost Missouri. It differs from *P. deltoides* in having hairy-margined bud-scales and very coarsely dentate leaves.

Plate no. 131. 1. *Populus heterophylla*, × 2/7. 2. *Populus* × *gileadensis*, × 2/7. 3. *Populus* × *eugenei*, × 2/7. 4. *Populus deltoides* var. *deltoides*, × 2/7; a. Male catkins, × 2/7; b. Fruits; b. Seed; c. Leaf; d. Flowering branch.

PLATE NO. 131

Fam. **LEITNERIACEAE** (Corkwood Family)

Leitneria floridana Chapm. Corkwood Map 738
Flowers March–April.

Occurs in wooded or open swamps and wet thickets along roadsides in the lowlands of southeastern Missouri, where known from Dunklin, Butler, and Ripley counties.

Ranges from Florida to Texas, north to Georgia, Arkansas, and southeastern Missouri.

This shrub or small tree attains a height of about 7.5 meters (25 feet), but often is only a little over a meter (3½ feet) tall. Plants are either male or female and form thickets by root suckers. The wood, which is lighter than cork, has the lightest weight of any woody plant native to the United States, weighing only 13 pounds per cubic foot, but is not as light as the Central American Balsawood (*Ochroma*). It is sometimes used for fishing-net floats and bottle stoppers.

The rather leathery, dark olive to dull green leaves,

reminding one of some kinds of similar foliage of tropical and subtropical plants, are 7–15 cm. long, and more or less crowded near the top of the new season's growth of the slender stem, which is slightly enlarged at the base and attains a diameter of not over 10–12.5 cm. (4–5 inches), and usually much less so.

The plant is quite hardy far north of its natural known geographical limits. Plants originally transplanted from Missouri to a pond in the author's wildflower garden northwest of Chicago have spread into a sizeable thicket in ten years. Moreover, plants succeed in dry soils, as can be testified by their growth at the Missouri Botanical Garden in St. Louis and at the Morton Arboretum west of Chicago. The leaves remain green until late in the autumn, and are still green well after most other woody plants have either turned color or dropped their leaves.

Fam. **JUGLANDACEAE** (Walnut Family)

Pith of twigs or branchlets, when cut lengthwise, separates into chambers or stepladder-like tiers; leaves usually with 11–19 (sometimes only 7) divisions, the middle divisions larger than those at the tip; male catkins not in groups of 3's, without stalks and appearing on branchlets of the previous year's growth; stamens glabrous, 8–40 on each flower of the male catkin; husk of fruit not splitting open, the shell furrowed 1. **JUGLANS**

Pith of twigs continuous and solid brown; leaves usually with 5–11 (sometimes up to 17) divisions, the topmost divisions generally largest; male catkins in groups of 3's, long- or short-stalked, appearing on the new season's growth; stamens hairy, 3–8 on each flower of the male catkin; husk of fruit splitting open, the shell smooth or slightly net-veined 2. **CARYA**

1. **Juglans** L. Walnut

- a. Pith of branches light brown, the brown part much thicker than the separating partitions; bark dark brown or black with rough ridges; upper part of leaf-scar of the previous year's leaves without any mat of hairs; fruit usually somewhat globe-shaped and about as broad as long (or rarely in *f. oblonga* longer than broad), the husk not sticky 1. **J. NIGRA**
- a. Pith of branches dark brown, the brown part about as thick as the separating partitions; bark gray with smooth ridges; upper part of leaf-scar of the previous year's leaves with a mustache-like mat of hairs; fruit longer than broad in the native tree, husk sticky, or globe-shaped or ovoid in the cultivated tree *b*
- b. Native tree; fruit longer than broad, 7–10 cm. long, occurring 2–5 together; nut with 4 prominent and 4 less prominent ridges 2. **J. CINEREA**
- b. (See excluded species); cultivated tree; fruit globe-shaped or ovoid, 5–6 cm. long occurring with as many as 20 in a long drooping raceme; nut rough, 2-edged 3. **J. AILANTIFOLIA**

1. **Juglans nigra** L. Walnut

Map 739

Flowers April–late May.

Occurs usually in rich woods at the base of slopes or bluffs, in valleys along streams, and in open and upland woods; sometimes planted or persisting in old

fields and pastures. Throughout Missouri and doubtless in every county.

Ranges from Massachusetts to Minnesota, South Dakota, and Nebraska, south to Florida and Texas.

Two variations are found in Missouri:

739 ● *Juglans nigra* f. *nigra* (Black Walnut)
 739 □ *Juglans nigra* f. *oblonga*

740 *Juglans cinerea* (Butternut)

741 *Carya illinoensis* (Pecan)

Common type with fruit globe-shaped, spherical, about as broad as long. . . . 1a. *J. NIGRA* f. *NIGRA*
 Rare type with fruit ellipsoid and longer than broad 1b. *J. NIGRA* f. *OBLONGA*

1a. ***Juglans nigra* f. *nigra*** Map 739

This is the form ordinarily encountered.

1b. ***Juglans nigra* f. *oblonga*** (Marsh.) Fern. Map 739

Known only from Howell (Pinebrook Farms on highway 14, Siloam Springs, 1948, *John T. Woodruff*) and Wayne (along road bordering swampy meadow in valley of Stanley Creek, T27N, R7E, sect. 18, 6-7 mi. northeast of Wappapello, September 11, 1949, *Steyermark 69265*) counties.

Known also in Virginia.

The foliage of the Black Walnut which turns to a light yellow shade in autumn serves as one of the hosts to the fall webworm (*Hyphantria cunea*), which forms webby masses over the ends of branches. Although much pollen is shed by this species, it does not appear to enter into hay fever cases, although it is sometimes suspected. The kernel of the nut is edible and walnut nutting parties are among autumn activities. Besides the obvious use of the plain nuts in a fresh or dried state, they were prepared in several ways as food by the Indians of the eastern United States in soups and gravies, and as butter. The early colonists pickled the young fruits, and the practice is occasionally continued today in various parts of the United States. The boiled sap of Black Walnut, tapped in early spring, was also used by the Indians as a sweet syrup.

Commercially, Black Walnut is one of the most important timber trees. It is the source of the best cabinet wood available in the United States, and is highly prized for its beautiful grain used in furniture and interior finish. For its durability it was used in building ships and boats. It is also the source of much

of the wood used in gunstocks, and at one time supplied much wood for railroad ties and rafters. Formerly, many rail fences were made from walnut. Missouri, Illinois, Indiana, and Ohio continue to furnish the bulk of the commercial supply of this species.

2. ***Juglans cinerea* L. Butternut** Map 740
 Flowers April-late May.

Occurs in rich woods along the base of slopes or bluffs, and along streams. Common in the Ozarks and eastern half of the state, north of the Missouri River ranging west to Putnam, Sullivan, Macon, Monroe, Audrain, and Howard counties, south of the Missouri River ranging west to Lafayette, Johnson, Henry, St. Clair, Cedar, Greene, Christian, and Barry counties.

Ranges from New Brunswick to North Dakota, south to Georgia and Arkansas.

Like Black Walnut, the nut of this species has a sweet edible kernel and has been used similarly by the Indians; the sap, likewise, was boiled by them for a sweet syrup. Also, like Black Walnut, the wood is highly valued for its grain and durability, furnishing wood for cabinetmaking and interior finish.

Small amounts are used as pulp when mixed with other hardwoods for papermaking. The bark of the root is sometimes employed in medicine as a liver stimulant, while the early settlers in this country prepared an orange and yellow dye from the bark and green fruits of this species and of the Black Walnut to color their homespun cloth.

Excluded species

3. ***Juglans ailantifolia* Carr.** Japanese Walnut
Juglans Sieboldiana Maxim., 1872 not *J. Sieboldiana* Goepfert, 1854 (fossil)
Juglans cordiformis Maxim. var. *ailantifolia* Rehd.

A specimen from a cultivated tree in Palmyra, Marion County, growing 3 blocks south of the hotel along highway 61 was collected on July 20, 1929 by Frederick Dunlap, former state forester, and deposited in the herbarium of the University of Missouri. As the species has not been found as an escape from cultivation, it is not included as an introduced member of the Missouri flora. It is native to Japan and cultivated in North America where it is hardy as far

north as Ontario. The Heartnut (*J. ailantifolia* var. *cordiformis* [Makino] Rehder) is similar, but with heart-shaped, smooth, and thinner-shelled nuts.

The Persian or English Walnut (*Juglans regia* L.) is planted in Missouri, but is not known as an escape from cultivation. It is an important nut tree in California, and is distinguished from the other walnuts by the 7-9 nearly entire, instead of toothed, leaflets.

2. *Carya* Nutt. Hickory

I. Key based on fruit, flowers, and vegetative characters

- a. Scales of bud (best seen on uppermost bud) 4-6, in pairs, valvate (edges touching but not overlapping); leaflets (divisions of 1 leaf) 5-17, often with one side wider or more curved than the other side (falcate); at least some of the male catkins arising from separate side buds located near the top of the branches of the previous year's growth; nuts thin-shelled; sutures on fruit (where the fruit splits) with definite wings or keels; scars of the bud-scales separate, rather broad, not forming a ring *b*
- b. Nut longer than broad; fruit longer than broad, 3.5-8 cm. long, nearly terete with usually rounded or curved sides or rarely compressed; clusters of male catkins without stalks (sessile) or nearly without stalks; leaflets mainly 9-17; lobes of the seed entire or with a slight notch at the end; winter buds with tiny clusters of yellow hairs *c*
- c. Leaflets usually 11-17, rarely 9; nut cylindric, ovoid-oblong, mostly terete with rounded or curved sides; nut sweet; common in many parts of southern, central, and eastern Missouri *1. C. ILLINOENSIS*
- c. Leaflets usually 9-13, rarely 7 or 15; nut compressed, oblong; nut bitter; rare, known only from the lowland swamps of Dunklin County, southeastern Missouri *2. C. × LECONTEI*
- b. Nut as broad as or broader than long; fruit either longer than broad or nearly as broad as long, 2-3.5 cm. long, strongly or somewhat flattened or compressed, more or less angled; clusters of male catkins with definite stalks (peduncles); leaflets mainly 5-13 (rarely 15); lobes of seed deeply 2-lobed; winter buds without yellow hairs, but with yellow scales which either remain attached or fall off *d*
- d. Found only in lowland swamps of southeastern Missouri; winter buds dark brown or reddish-brown, with yellow glands which disappear eventually; leaflets 7-13 (rarely 15), the lower surface glabrous or nearly so when mature and without rust-colored hairs; stamens 3-6 to each flower of the male catkin; husk of fruit winged to the base and splitting to the base when mature; shell of nut furrowed or wrinkled, reddish-brown *3. C. AQUATICA*
- d. Found throughout the state in low woods or rich slopes; winter buds mustard-yellow or orange-yellow, the yellow glands remaining permanently attached; leaflets mostly 7-9, rarely 5 or 11, the lower surface, even when mature, with pubescence and with rusty-colored scales; stamens 4 to each flower of the male catkin; husk of fruit not winged near the base and splitting only to just below middle when mature; shell of nut rather smooth, gray *4. C. CORDIFORMIS*
- a. Scales of bud (best seen on uppermost bud) 6-12, overlapping (imbricate); leaflets (divisions of 1 leaf) 3-9, usually not falcate or only barely so; clusters of male catkins all arising from the bud-scales located at the lowest part of the leafy shoot of the present season during which it was collected; nut usually thick-shelled; sutures on fruit (where the fruit splits) with no wings or keels or at most very slightly keeled; scars of bud-scales coming together, very narrow, forming a definite ring *e*
- e. Uppermost (terminal) bud large, mainly 12-30 mm. long, with 10-12 scales; fruit 3.5-7 cm. long with a husk 4-12 mm. thick; nut usually noticeably angled; branchlets usually stout *f*
- f. Leaflets usually 5, or, if rarely 7, then the teeth provided with persistent dense hairy tufts just below the tip of each tooth, or the petioles, young branchlets, and lower surface of leaves not covered with curly hairs, or the fruit splitting to the base, or the shell of the nut only 1-2 mm. thick *5. C. OVATA*
- f. Leaflets usually 7-9, or if rarely 5, then the shell of the nut 3-6 mm. thick, or the young branchlets, petioles, and lower surface of leaves covered rather densely with curly hairs, or

- the fruit not splitting to the base, or the teeth of leaves lacking dense hairy tufts just below their tips g
- g. Trees usually of dry or high ground; bark of trees always tight, not shaggy; 1st year branchlets brown or reddish-brown; leaf-stalks and axis of leaves, lower surface of leaves, and young branchlets covered with dense, rather persistent, curly hairiness; shell of nut 5-6 mm. thick; husk of fruit not splitting to the base; outer bud-scales of uppermost bud falling in autumn to expose the inner silky bud-scales 7. *C. TOMENTOSA*
- g. Trees of low or alluvial ground; bark of old trees loosening, shaggy; 1st year branchlets brown-orange or tan; leaf-stalks and axis of leaves, lower surface of leaves, and young branchlets either glabrous (without hairs) or slightly short-hairy or scurfy, but not covered with a dense persistent curly hairiness; shell of nut 3-6 mm. thick; husk of fruit splitting to the base; outer bud-scales of uppermost bud remaining attached to bud from autumn until the following spring 6. *C. LACINIOSA*
- e. Uppermost (terminal) bud smaller or medium-sized, mainly 6-12 mm. long, with 6-10 scales; fruit 1.5-4 cm. long with a husk 1.5-4 mm. (rarely 5) thick; nut either rounded or angled; branchlets usually slender h
- h. Outer bud-scales, young branchlets, young leaves, and male catkins with a rusty pubescence or scurfiness; nut dark reddish-brown, the shell with a conspicuous pale network; bark dark. 10. *C. TEXANA*
- h. Outer bud-scales and young branchlets glabrous (without hairs) or with a pale hairiness; nut pale brown, the shell lacking a conspicuous network; bark gray i
- i. Trees of southeastern Missouri only; leaflets most commonly 5, rarely 7; bark of old trees tight, furrowed, and ridged, not separating into small or long plates or small scales; husk of fruit not splitting or splitting only above the middle, dark brown, shining; nut smooth; shell of nut about 1.5 mm. thick; female flowers and bracts covered with a fine gray short hairiness; male catkins 5-8 cm. long, their bracts with noticeable hairs. 8. *C. GLABRA*
- i. Trees of southern, central, and eastern Missouri: leaflets most commonly 7, rarely 5; bark of trunk a few feet above the ground usually slightly scaly, on mature trees separating into longer plates; husk of fruit eventually splitting all the way to base, light brown, dull, warty; nut angled; shell of nut thinner, less than 1.5 mm. thick; female flowers and bracts covered with a yellow scurfiness; male catkins 8-17 cm. long, their bracts minutely hairy (puberulent). 9. *C. OVALIS*

II. Alternate key based on foliage and buds

The following key is adapted from the treatment by Dr. Wayne Manning (Rh. 52: 196-99. 1950), whose work on the genus is the most complete and detailed to date (*Carya* × *Lecontei*, considered a hybrid between *C. illinoensis* and *C. aquatica*, is not keyed out here, but in other key).

- a. Scales of bud 4-6, in pairs, valvate (edges touching but not overlapping); buds often yellow or orange-yellow, rather flattened; leaflets 7-17, never only 5, either always or else sometimes more curved and wider on one side than the other (falcate) b
- b. Leaflets mostly 7-9, rarely 5 or 11, sometimes or rarely falcate; terminal leaflet mostly sessile (without a stalk), rarely short-stalked 4. *C. CORDIFORMIS*
- b. Leaflets mostly 11-17, rarely 7-9, strongly falcate; terminal leaflet stalked. c
- c. Teeth of leaflet usually prominent; side veins of leaflets not crowded, branching rather freely near the tips, these branches usually curving downward and passing to the center of the tooth 1. *C. ILLINOENSIS*
- c. Teeth of leaflets usually quite inconspicuous; side veins of leaflets crowded (usually about 30 pairs), about 1 to each tooth, rarely branching at the tip, many of them ending at the sinus (space between teeth). 3. *C. AQUATICA*
- a. Scales of buds 6-12, overlapping (imbricate); mature buds brown or gray, sometimes covered with yellow glands, plump, not flattened but more or less curved or rounded on all sides; leaflets mainly 5-9, not falcate d
- d. Margins of leaflets strongly hairy when young, each tooth with a persistent dense tuft of hairs on one or both sides of the tooth just below its tip (many of the tufts disappear on some of the leaflets towards autumn); leaflets typically 5 (rarely 7); branchlets of the present year (youngest) usually hairy; topmost bud 10-27 mm. long, the outermost scales persistent and remaining attached 5. *C. OVATA*

- d. Margins of leaflets sometimes hairy when young with groups (fascicles) of hairs, but teeth without dense tufts of hairs just below the tip; leaflets 5-9; leaflets and leaf-axis (rachis) glabrous or glabrate (mostly without hairs) on those species having only 5 leaflets, or with the margins not hairy, or with the twigs slender and glabrous, or with the outermost bud-scales falling off in autumn e
- e. Branchlets stout; lower surface of leaflets densely hairy, most of the hairs in groups (fascicles); mature topmost bud 10-27 mm. long; branchlets of the present year hairy, at least early in season, or else branchlets light orange or buff in autumn; leaflets 7-9, never 5 alone, the margins usually hairy, especially early in the season; outer bud-scales either falling or persistent f
- f. Twigs or branchlets tan, buff, or pale orange at least on one side, gray on the other; hairs on axis of leaf (rachis) not in groups (fascicles), usually straight, the axis of the leaf (rachis) frequently almost glabrous; bark shaggy; outer leathery bud-scales of topmost bud persistent; leaf-stalks (petioles) often remaining attached in winter 6. *C. LACINIOSA*
- f. Twigs or branchlets brown; hairs on axis of leaf (rachis) in separated groups (fascicles), curly; axis of leaf (rachis) mostly hairy; bark deeply ridged, not shaggy; outer bud-scales of topmost bud falling off, leaving the light grayish-brown silky-hairy inner bud-scales exposed; leaf-stalks (petioles) usually fallen from the branches by winter 7. *C. TOMENTOSA*
- e. Branchlets slender; lower surface and side veins of lower surface of leaflets mostly glabrous (sometimes hairy in *C. texana* var. *villosa*); mature topmost bud short, 5-12 mm. long; branchlets of the present year glabrous, in autumn reddish- or chestnut-brown; leaflets 5 alone on some trees, 5-9 in others, the margins usually glabrous (without hairs) or glabrate; outer bud-scales falling early g
- g. Outer bud-scales, young branchlets, and young leaves with a rusty hairiness or scurfiness; young leaflets with numerous reddish or rusty-colored scales; twigs and axis of leaf (rachis) sometimes with hairs in groups (fascicles) 10. *C. TEXANA*
- g. Outer bud-scales and young branchlets glabrous or with a pale hairiness; young leaflets without reddish or rusty-colored, but with scattered dark scales; twigs not hairy; axis of leaf (rachis) glabrous, or if hairy, the hairs crowded, not in fascicles h
- h. Leaflets usually 7, or 5 and 7, usually ovate to obovate or oblanceolate, thickish; leaf-stalk (petiole) frequently red; topmost buds ovate, blunt or acute, the tips of the outer bud-scales often hairy; bark of trunk scaly or shaggy in older trees 9. *C. OVALIS*
- h. Leaflets usually 5, rarely 5 and 7, the lateral usually lanceolate or oblong-elliptic, rather thin; topmost buds usually lanceolate, acuminate, the tips of the outer bud-scales glabrous; bark of trunk tight, not scaly 8. *C. GLABRA*

1. ***Carya illinoensis*** (Wang.) K. Koch Pecan

Map 741

Carya Pecan (Marsh.) Engl. & Graebn. [P & S]

Flowers April-May.

Occurs on alluvial soils of river bottom flood plain in woodland and margins of river bottom prairie; often growing alone in open fields where other trees have been cut away; sometimes cultivated, forming open groves. Common along the counties in eastern and central Missouri bordering the Mississippi, the Missouri, Osage, South Grand, and Grand rivers, scattered elsewhere along a few other rivers; generally absent from most of the Ozark section and much of northwestern and extreme northern Missouri.

Ranges from Alabama to Texas, north to Ohio, Indiana, Illinois, and Iowa; also in Mexico.

Pecan is the state tree of Texas. It is the most

important hickory from the standpoint of hay fever, and often is ranked next to ragweed in its importance. The bark on Pecan is deeply and irregularly divided into narrow ridges and is not loose.

Unlike other hickories, which are noted for their strength and tenacity, the wood of the Pecan is rather weak and poor in comparison, and for that reason was used chiefly for fuel, although occasionally it was used also in the manufacture of wagon and agricultural implements. The nuts, however, produced by the tree, give to it the honor of being the best of the native nut-bearing trees of North America. Nuts from the wild trees are much smaller than those from cultivated and improved varieties, of which well over a hundred horticultural types are known, including the so-called 'paper-shelled.'

Georgia is the leading pecan-growing state, but

742 *Carya X Lecontei* (Bitternut Hickory)743 *Carya aquatica* (Water Hickory)744 • *Carya cordiformis* f. *cordiformis* (Bitternut Hickory)
744 □ *Carya cordiformis* f. *latifolia*

pecan orchards do well in the Pacific states of California, Oregon, and Washington, and are grown especially in the southern states. There are a number of pecan orchards in Missouri, especially in the southeastern section of the state. Pecans are reputed to have a higher percentage of fat (over 70 per cent) than that of any other vegetable. The shells themselves yield a tannin and have been employed as mulches for covering roses, etc.

2. *Carya* × *Lecontei* Little

Bitternut Hickory

Map 742

Carya aquatica × *Carya illinoensis*

Carya texana (Le Conte) C. DC., 1862 and auth.

[*Steyerm.*], not *G. texana* Buckl., 1860

Flowers April–May.

Known only from the lowlands of southeastern Missouri in Dunklin County (near Campbell, September 4, 1935, Kellogg 27036).

Ranges from Missouri and Arkansas, south to Mississippi, Louisiana, and Texas.

Mr. E. J. Palmer (Jour. Arn. Arb. 18: 133–35, 1937) has shown that this should be considered a hybrid between *C. aquatica* × *C. illinoensis*, and it has been recognized as such by the U.S. Forest Service. It combines the bitter seeds and compressed fruit of *C. aquatica*, and the sessile male catkins, yellow, hairy winter buds, and elongate nut, which is longer than broad, of *C. illinoensis*.

The bark is roughened with platelike scales which are rather closely appressed to the main trunk. The winter buds are covered with pale yellow hairs. The fruit is oblong or oblong-obovoid, more or less covered with yellow scurfiness, and 3.5–5 cm. long. The nut has a thin papery shell, is oblong-ovoid, compressed, and obscurely 4-angled.

3. *Carya aquatica* (Michx. f.) Nutt.

Water Hickory

Map 743

Flowers April–May.

Occurs in swamps and low wet woods in the lowlands of southeastern Missouri north to Bollinger and west to Ripley County.

Ranges from Florida to Texas, north to Virginia, Illinois, and Missouri.

The bark separates into long and thin plates or scales. The compressed nut resembles the shape of the next species, *C. cordiformis*, but, in addition to the differences mentioned in the key, is more or less 2-celled at the base, whereas in *C. cordiformis* the nut is 4-celled at the base and lower half.

4. *Carya cordiformis* (Wang.) K. Koch

Bitternut Hickory, Pignut Hickory

Map 744

Flowers April–May.

Occurs in alluvial and rich soils, either in low woods and river bottoms along streams, sloughs, and ponds, or at the base of rich slopes and bluffs. Throughout Missouri.

Ranges from Florida to Texas, north to New Hampshire, Quebec, Ontario, Michigan, Wisconsin, Minnesota, and Nebraska.

Missouri material may be divided into two variations:

Leaflets mainly 2–4 (rarely 4.5) cm. broad . . .

4a. *C. CORDIFORMIS* f. *CORDIFORMIS*

Leaflets mainly broader, 5–10 cm. broad. . .

4b. *C. CORDIFORMIS* f. *LATIFOLIA*

4a. *Carya cordiformis* f. *cordiformis* Map 744

Throughout Missouri and doubtless in every county; this is the commoner form encountered.

4b. *Carya cordiformis* f. *latifolia* (Sarg.)

Steyerm.

Map 744

747 □ *Carya tomentosa* var. *subcoriacea*

at all seasons of the year easily distinguish this species. The bark is shallowly and irregularly furrowed, tight, and light gray. The kernel, as in *C. aquatica* and *C. x Lecontei* is bitter. The wood is very strong and tough, and has been used for fuel, hoops, and ox-yokes. It is stated that the shaven bark has been used by manufacturers under the name of 'yellow-bud' hickory for the making of chairs with split-bottoms.

It is reported that the early settlers obtained from the nut an oil used in their lamps as well as in the role of a rheumatism medicine.

5. ***Carya ovata*** (Mill.) K. Koch
Shagbark Hickory
Flowers April-May.

Map 745

Occurs in lowland or upland woods, in either valleys along streams, or on slopes, limestone hills, and dry upland areas.

Ranges from Florida to Texas, north to Maine, Quebec, Ontario, Michigan, Wisconsin, Minnesota, and Nebraska.

Missouri material is represented by the following variations, of which some may be distinguished only in fruit:

- a. Larger leaflets 2.5-5 cm. wide; fruit smaller than in other forms, 3 cm. long; nut 2.3-3 cm. long, 1.6-2.4 cm. broad, 1-1.6 cm. thick, not depressed at apex; husk of fruit 4-5 mm. thick.
5d. *C. OVATA* f. *FRAXINIFOLIA*
- a. Larger leaflets 5-11 cm. wide; fruit larger, 3.5-6 cm. long b
- b. Nuts ellipsoidal, much longer than broad, abruptly narrowed and long-pointed at one end 5c. *C. OVATA* f. *ELLIPSOIDALIS*
- b. Nuts top-shaped, obovoid, nearly globe-shaped or somewhat broadly bean-shaped, only slightly longer than broad or broader than long, at most short-pointed c
- c. Fruit 3.5-6 cm. long; nut obovoid, ovate,

or oval, slightly compressed or flattened, 2-3 cm. long, 1.5-2.5 cm. broad, more or less pointed at tip . 5a. *C. OVATA* f. *OVATA*
c. Fruit smaller; nut subglobose or nearly rounded, or obcordate, strongly compressed, 1.5-2 cm. long, 1-1.5 cm. broad, rarely pointed at tip . . . 5b. *C. OVATA* f. *NUTTALLII*

5a. ***Carya ovata* f. *ovata*.** Map 745
Carya ovata (Mill.) K. Koch [G, BB, P & S]

5c. ***Carya ovata* f. *ellipsoidalis*** (Sarg.) Map 745
Steyerm.
Carya ovata var. *ellipsoidalis* Sarg. Bot. Gaz. 66: 235. 1918 [P & S]

Known definitely from Marion (near Hannibal, September 5, 1913, Davis 2071, holotype) and Ralls (Oakwood, September 13, 1913, Davis 2132) counties, and reported but not collected by Palmer from Johnson County.

5d. ***Carya ovata* f. *fraxinifolia*** (Sarg.) Map 745
Steyerm.
Carya ovata var. *fraxinifolia* Sarg. Trees and Shrubs 2: 207. 1913 [G]

Known from Clark, Pike, St. Louis, and Jefferson counties, and probably more widespread over the state.

The bark of older trees of *C. ovata* separates into

long thin strips a foot or more long; that of young trees is tight and nonscaly, but the bark begins to scale after a growth of 1–2 dm. in diameter has been reached.

Much more field work and experimental studies need to be carried out on the variation of nuts in this species before any final opinion can be rendered about the various forms treated. Some authors (Gleason) have not recognized the variations as sufficiently significant to possess nomenclatural value. Others (Fernald, Deam) have maintained them as varieties, even though Deam admits that 'no dependence can be placed upon... size or shape of nuts' (*Trees of Indiana*, p. 71, 2nd ed. 1932). As the variations in leaf width, and shape and size of fruit and nut appear to be characters which may appear here and there throughout the range of the species, and as extremes of variation, it appears preferable here to treat them all as forms, not varieties.

The leaves of this species become dull gold or deep yellow in the fall, changing color at the beginning of autumn. This is one of the principal species of *Carya*, other than *C. illinoensis*, whose pollen is known to be responsible for causing hay fever. The flesh of the nut is sweet and, after the Pecan, is usually accorded second place in taste quality among the sweet-fleshed hickories. As with the walnuts, the sap of this and other species of hickory can be boiled for its sweet-yielding syrup or sugar, much as in the Sugar Maples. A particularly good sugar is reputed to come from the Shagbark Hickory. The Indians used the oily portion of the boiled liquid in their cookery.

The wood of this species is very strong and tough. It generally has fewer knots and badly formed spots than any of the other species, and has been employed in the manufacture of ax handles, skis, various agricultural implements, barrel hoops, wagons, carriages, and baskets. This species of hickory is widely used for fuel, ranking next to *Robinia Pseudo-acacia* (Black Locust) in value, while the green wood of this and other hickory species is greatly esteemed and used for barbecuing various meats. It burns long with little or no smoke, similar to the wood of ash, and thus is unexcelled for outdoor cooking. The straight young saplings often are made into walking sticks. Early colonists and pioneers employed the inner bark as a yellow dye for their homespun cloth.

6. *Carya laciniosa* (Michx.) Loud.

Big Shellbark Hickory, Kingnut

Map 746

Flowers April–May.

Occurs in low alluvial woods of valleys along streams and in river flood plain, often associated with *Carya cordiformis*, *C. Pecan*, *Quercus palustris*, and other trees favoring wet woodland. Found mostly along the larger streams in eastern, northern, central, and western Missouri, common in the tall swamp forests of the southeastern lowland section, but absent from a large part of the Ozark region.

Ranges from New York and Ontario to Iowa and Nebraska, south to North Carolina, Georgia, Alabama, Louisiana, Kansas, and Oklahoma.

The leaflets normally are 7 or 9, but occasionally may be 5. The upper leaflets average larger than those of the Shagbark Hickory (*C. ovata*), varying from 1.2–2.3 dm. long and 7–12 cm. broad, the terminal leaflet sometimes attaining a length of 2.3 dm. The fruit is only slightly longer than that of *C. ovata*, becoming 6.5 cm. long, but the nut is much larger, being 3–6 cm. long instead of 2–3 cm. long as in *C. ovata*. The shell of the nut in *C. laciniosa* is yellow-brown to red-brown; in *C. ovata* it is pale to whitish-brown.

Those who have tasted the sweet kernels of *C. laciniosa* often prefer it to the much-esteemed *C. ovata*. Both are of excellent quality. The hard nuts are rendered more easily cracked by first soaking them and then allowing them to dry, the heat splitting the shell sufficiently to make it easier to crack them open. The various high qualities possessed by the wood of *C. ovata* apply equally well to that of *C. laciniosa*.

6a. *Carya* × *Nussbaumerii* Sarg.

Map 746

Carya illinoensis × *laciniosa*

This hybrid is known from the vicinity of Rockville, Bates County, western Mo. It is found also in Illinois, Indiana, and Iowa.

It has leaves similar to those of *C. laciniosa*, slender branchlets and shape of fruit of *C. illinoensis*, white or nearly white nuts, and fruit which lacks wings on the sutures.

7. *Carya tomentosa* Nutt. Mockernut Hickory

Also called White Hickory.

Map 747

Flowers April–May.

Occurs mostly in dry upland woods on high ridges or slopes, frequently in acid soils overlying sandstone, chert, flint, or granite, occasionally in low or alluvial woods along streams. Throughout Missouri, except absent from the extreme southeastern lowland corner

PLATE NO. 133

and most of the extreme northern and northwestern Missouri sectors.

Ranges from Florida to Texas, north to Massachusetts, New Hampshire, New York, Ontario, Michigan, Illinois, Iowa, and Nebraska.

Missouri material is represented by the following variations, which can be distinguished only by mature fruit:

- a. Dried fruit oblong, longer than broad, 5 cm. long; nut oblong to ovate, 4.5 cm. long, strongly angled, pointed at both ends or sometimes more rounded at base; leaflets thick, very hairy on lower surface . . . 7d. *C. TOMENTOSA*
var. *SUBCORIACEA*
- a. Dried fruit usually globe-shaped or round, rarely ovoid, obovoid, or shortly ellipsoid, broader than long or slightly longer than broad, 3–3.5 cm. long; nut somewhat round or globe-shaped, rarely ellipsoid, somewhat longer than broad or broader than long, 2.5–3.5 cm. long, short- to long-pointed at top and rounded or pointed at the base, 4–6-angled; leaflets thinner, less hairy on lower surface. . . b
- b. Fruit with a long-pointed (long acuminate) summit . . . 7b. *C. TOMENTOSA*
var. *TOMENTOSA* var. *OVOIDEA*
- b. Fruit short-pointed (acute) or gradually narrowed at summit. . . c
- c. Fruit obovoid with a prominent stalk-like base. 7c. *C. TOMENTOSA* var. *TOMENTOSA*
f. *FICOIDEA*
- c. Fruit ellipsoidal or obovoid, gradually narrowed at the base, not with any stalk-like base. 7a. *C. TOMENTOSA* var. *TOMENTOSA*
f. *TOMENTOSA*

Carya tomentosa Nutt. [G, BB, P & S]

This is the most commonly encountered form in Missouri.

7b. *Carya tomentosa* var. *tomentosa* f. *ovoidea* (Sarg.) Palmer & Steyererm. Map 747
Carya tomentosa f. *ovoidea* (Sarg.) Palmer & Steyererm. [P & S]

Known only from McDonald County (Noel, September 5, 1913, *Palmer 4119*, holotype in herb. Arnold Arboretum; same locality, October 23, 1910, *Palmer 3287*), southwestern Missouri.

7c. *Carya tomentosa* var. *tomentosa* f. *ficoidea* (Sarg.) Palmer & Steyererm. Map 747
Carya tomentosa f. *ficoidea* (Sarg.) Palmer & Steyererm. [P & S]

Known only from Barton and Jasper (sandy soil in Mt. Hope Cemetery, Webb City, October 8, 1911, *Palmer & Sargent 3493*, holotype in herb. Arnold Arboretum) counties, southwestern Missouri.

7d. *Carya tomentosa* var. *subcoriacea* Sarg.

Map 747

Known mostly from southernmost Missouri, and locally in Linn County.

Ranges from Missouri and Arkansas to Oklahoma and Texas.

Some authors (Gleason and Fernald) do not consider the variations treated above as more than 'merely phases in the normal variation of the species.' However, Deam, who had first-hand knowledge of var. *subcoriacea*, considered it as a distinct and separable variety. Until more detailed field and experimental studies have been completed on the variations found in the fruits and nuts of this species, it would seem preferable to maintain most of the variations as forms occurring here and there in the range of the common variation, and one of them, var. *subcoriacea*, as a variety with a marked southern geographical range.

The bark in *C. tomentosa* is tight, shallowly furrowed, usually thick and densely covered with lichens. In certain river bottom areas the bark may be thinner and lighter colored.

This species has unusually fragrant resinous foliage, although all the hickories possess a resinous fragrance. The wood has been shown to be the strongest of any of the species of hickory, and is highly prized for making into splints and rustic furniture. The name White Hickory is derived from the whitish sapwood, which in *C. tomentosa* is much whiter than usual.

8. *Carya glabra* (Mill.) Sweet var. *glabra*

Pignut Hickory

Map 748

Also called Broom Hickory; in Indiana called Black Hickory.

Flowers April–May.

Occurs in usually acid sandy or gravelly soils of dry or upland wooded ridges. Southeastern Missouri, where it is found on Crowley Ridge in Dunklin, Stoddard (top of Crowley Ridge, north of Ardeola school, near Ardeola, November 8, 1936, *Steyermark 20772*), and Scott (top of ridge above east-facing sandstone slopes along Mississippi River, T29N, R14E, sect. 13, 2 mi. north of Commerce, November 7, 1936, *Steyermark 20746*) counties, and at the edge of the Ozark escarpment in Cape Girardeau County. The specimen from Stoddard County (*Steyermark*

750 • *Carya texana* var. *texana* f. *texana* (Black Hickory)
 750 x *Carya texana* var. *texana* f. *glabra*
 750 □ *Carya texana* var. *villosa*

20772) has fruits approaching the larger size of var. *megacarpa* Sarg.

Ranges from Massachusetts and Vermont to Ontario, south to Georgia, Alabama, Mississippi, Illinois, Missouri, and Arkansas.

This species and the following, *C. ovalis*, are combined by some botanists. As there appear to be justifiable grounds for maintaining the two as distinct, a view held by Dr. Wayne Manning, current authority on the genus, both hickories are accorded full specific rank in the present work.

The bark of *C. glabra* is close and tight, shallow to deeply furrowed, and generally dark. Similar uses are found for the wood of this hickory, as for that of other species, such as for tool handles, manufacture of agricultural implements, wagons, chairs and other furniture, skis, sulkies for trotting horses, and fuel. Early settlers split strips of the small saplings of this species to make into brooms, hence the name Broom Hickory in some sections of the eastern states.

This species is considered to be one of those of the genus responsible for causing hay fever.

9. *Carya ovalis* (Wang.) Sarg.

False Shagbark

Map 749

Also called Sweet Pignut, Red Hickory, Small-fruited Hickory.

Flowers April–May.

Occurs mostly in dry or upland, rocky or nonrocky woods, usually in acid soils derived from or overlying chert, flint, sandstone, or granite. Throughout the Ozark region of southern and central Missouri north-east to an unglaciated section of Marion County.

Carya ovalis is united with *C. glabra* by the United States Forest Service, but is held to be distinct from that species by other botanists, including Deam, E. J. Palmer, and the current authority on the genus,

Dr. Wayne Manning. While many trees are found with fruits intermediate between the two types of hickory, and certain separation of *C. glabra* from *C. ovalis* depends upon collection of mature fruit in late autumn, extreme trees of the two types appear distinct and they are being maintained in the present treatment as species following Dr. Manning's studies (see Rh. 50: 191–92. 1948).

The following variations are found in Missouri, but can be distinguished mainly by mature fruits:

- a. Lower surface of leaflets conspicuously covered with glands and rather sticky; fruit small, 1.3–1.5 cm. thick, splitting to the base along the sutures which are distinctly broadly winged
 gc. *C. OVALIS* var. *ODORATA*
- a. Lower surface of leaflets not conspicuously covered with glands; fruit larger, 1.5–3 cm. thick, splitting to the base along the sutures which are not winged or at most with a narrow wing or keel b
- b. Fruit broadest in upper half, narrowed at the base (obovoid) gd. *C. OVALIS* var. *OBOVALIS*
- b. Fruit either as broad as long and more or less globe-shaped and round, or broadest in the middle and tapering or narrowed at each end (ellipsoid) c
- c. Nut narrowed at the summit to a short point, ovoid to ellipsoid . . . 9a. *C. OVALIS* var. *OVALIS*
- c. Nut rounded and broadest above the middle to a rounded, slightly or definitely heart-shaped summit d
- d. Branches of the 1st year (youngest) rather short-hairy, those of older growth of 2nd and 3rd year more or less hairy . 9c. *C. OVALIS* var. *OBCORDATA* f. *VESTITA*
- d. Branches more or less glabrous . . . 9b. *C. OVALIS* var. *OBCORDATA* f. *OBCORDATA*

- 9a. ***Carya ovalis* var. *ovalis*** Map 749
Carya ovalis (Wang.) Sarg. [G, P & S]
Carya glabra var. *glabra* in part, of [Little], not *C. glabra* (Mill.) Sweet

Known in southeastern Missouri from Ste. Genevieve (wooded upland slopes overlying LaMotte sandstone near Pickle Creek, 3 mi. west of Pickle, February 3, 1934, *Steyermark* 7755) and Dunklin counties.

Ranges from Massachusetts to Wisconsin and Iowa, south to Georgia, Alabama, Mississippi, and Missouri.

Carya glabra var. *glabra* in part, of [Little], not *C. glabra* (Mill.) Sweet

Generally common in the Ozark region of southern and central Missouri northeast to Marion County.

Ranges from Massachusetts to Indiana and Missouri, south to Georgia, Alabama, and Arkansas.

- 9e. ***Carya ovalis* var. *odorata*** (Marsh.) Sarg. Map 749
Carya glabra var. *glabra* in part, of [Little], not *C. glabra* (Mill.) Sweet

Known only from Madison and Iron counties in the southeastern Ozark section.

Ranges from Massachusetts to Ontario, south to Georgia, Mississippi, and Missouri.

The bark of *C. ovalis* and its varieties is more or less scaly as in Shagbark Hickory (*C. ovata*), but this does not flake off in plates as thin or large as in that species. On the lower 5–12 feet of trunk of older trees, the bark is tight, close, and slightly ridged. As in other members of the genus, the wood of this hickory is used in similar ways for tool handles, manufacture of agricultural implements, wagons, and for fuel.

Since this species is closely related to *C. glabra*,

which is believed to be one of those responsible for hay fever, it is likely that *C. ovalis* also may cause some cases.

10. ***Carya texana*** Buckl. Black Hickory Map 750
Also called Ozark Pignut Hickory.
Flowers April–May.

Occurs in dry or rocky upland woods, usually in acid soils derived from or overlying chert, flint, sandstone, or granite.

Common in the Ozarks throughout southern and central Missouri and northeast in unglaciated territory to Marion County.

Ranges from Louisiana and Texas, north to Indiana, Illinois, Missouri, and Oklahoma.

Missouri material may be divided into the following variations:

- a. Young branchlets, veins and midrib of lower surface of fully grown leaflets, as well as lower surface itself, glabrous (without hairs) or nearly so to the end of the season. 10b. *C. TEXANA* var. *TEXANA* f. *GLABRA*
a. Young branchlets and lower surface or midrib or veins of lower surface of fully grown leaflets more or less hairy to the end of the season . b
b. Midrib or veins of lower surface and/or lower surface of fully grown leaflets covered with rusty or tawny hairs; leaf-stalk (petiole) and axis of leaf (rachis) glabrous or nearly so at maturity, rarely with hairs .
10a. *C. TEXANA* var. *TEXANA* f. *TEXANA*
b. At least the midrib of lower surface and usually the complete lower surface of mature leaflets densely covered with hairs; leaf-stalk (petiole) and axis of leaf (rachis) usually quite hairy . 10c. *C. TEXANA* var. *VILLOSA*

- 10a. ***Carya texana* var. *texana* f. *texana*** Map 750
Carya texana Buckl., in part [G, Little], not *C. texana* C. DC.

Carya Buckleyi var. *arkansana* [BB, P & S, Steyermark.]
Carya texana var. *arkansana* (Sarg.) Little

This is the commonest variation encountered in Missouri.

- 10b. ***Carya texana* var. *texana* f. *glabra***
(Palmer & Steyermark.) Steyermark. Map 750
Carya Buckleyi var. *arkansana* f. *glabra* Palmer & Steyermark., Ann. Mo. Bot. Gard. 25: 770–71. 1938. [Steyermark.]

Scattered within the range of var. *texana* f. *texana* in Missouri in Dunklin, Butler (*Steyermark* 11461, holotype in Mo. Bot. Gard. Herb.), Reynolds, Maries, and Jasper counties.

- 10c. *Carya texana* var. *villosa* (Sarg.) Little
Map 750
Carya Buckleyi var. *villosa* (Sarg.) Sarg. [BB, P & S, Steyererm.]
Carya texana Buckl. in part [Little], not *C. texana* C. DC.

Of frequent occurrence in the Ozark region of southern and central Missouri northeast to Marion County, but less common than typical *C. texana* var. *texana* f. *texana*.

Known only from Missouri, but to be expected in adjacent states bordering the range of var. *villosa*.

The bark of *C. texana* and varieties is tight, thick, and deeply furrowed. The wood is hard and brittle and often used for fuel. The foliage has a beautiful

yellow color in autumn. It is often attacked by the fall webworm (*Hyphantria cunea*) which forms webby masses over the ends of branches.

On the drier upland ridges, on level upland, and on upper slopes of hills where chert, sandstone, or granite impregnate the soil, this species is abundant, occurring with various species of oak, such as *Quercus alba*, *Q. velutina*, *Q. coccinea*, *Q. marilandica*, *Q. stellata*, and *Q. falcata* (in the southern part of the state), pine, other hickories, such as *C. tomentosa*, *C. ovata*, and *C. ovalis*, flowering dogwood (*Cornus florida*), and shrubs, such as Deerberry (*Vaccinium stamineum*), Tree Huckleberry (*Vaccinium arboreum*), and Lowbush Blueberry (*Vaccinium vacillans*).

Order FAGALES

Fam. CORYLACEAE (Hazel Family)
(Betulaceae Birch Family [BB, P & S, Steyererm.])

I. Key based on bark and mature leaves

- a. Lower surface of leaves whitish or gray-white; bark peeling off in reddish-brown papery strips, exposing a pale smooth layer 4. BETULA
- a. Lower surface of leaves green or pale green, not white or gray-white; bark smooth or rough, not peeling b
- b. Leaf-blades with a blunt or rounded tip and rounded teeth 5. ALNUS
- b. Leaf-blades with a pointed (acute or acuminate) tip or pointed teeth, or with both c
- c. Leaf-blade usually with 5-8 veins on each side of midrib 1. CORYLUS
- c. Leaf-blade usually with 9-15 veins on each side of midrib d
- d. Bark smooth, twisty, blue-gray; lower surface of fully grown leaves glabrous (without hairs), except for some hairy tufts in the axils of the veins; none of the lower large lateral nerves forked 3. CARPINUS
- d. Bark scaly, light brown or brownish-gray; lower surface of fully grown leaves mostly hairy; some of the lower large lateral nerves forked 2. OSTRYA

II. Key based on flowers, fruits, and immature leaves

- a. Female catkin resembling a small pine cone, its bracts woody and long-persisting; base of catkin or main supporting stalk of flowering portion glabrous (without hairs); flowering catkins appear before the leaves 5. ALNUS
- a. Female catkin not as above; base of catkin or main supporting stalk of flower portion densely hairy b
- b. Flowering catkins appear usually before the leaves; flowering female catkin very small, few-flowered, and inconspicuous, 5 mm. long or less, with red or rose-colored short hair-like stigmas; mature fruit a nut 10-15 mm. long enclosed in a leafy involucre 1. CORYLUS
- b. Flowering catkins appear usually with the leaves; flowering female catkin conspicuous, many-flowered, 10 mm. or more long, lacking the red stigmas; mature fruit 3-5 mm. long c
- c. Female catkins closely-flowered, their scales densely overlapping, showing no space between; anthers glabrous (without hairs); male flowers with a calyx; female flowers without a calyx; nut winged 4. BETULA
- c. Female catkins loosely-flowered, their scales loosely overlapping with much space exposed in between; anthers hairy at tip (use magnifying lens); male flowers without a calyx; female flowers with a calyx; nut wingless d

- d. Each bract of female or fruiting catkins 2-3-lobed, flat, open, and attached to or subtending the ovary or nut; bracts of flowering female catkins glabrous or sparsely hairy; male catkins enclosed in bud-scales in winter 3. *CARPINUS*
- d. Each bract of female or fruiting catkins unlobed, bladderly, closed, surrounding an ovary or nut; bracts of flowering female catkins densely hairy; male catkins naked in winter, not enclosed in bud-scales 2. *OSTRYA*

1. *Corylus* L. Hazelnut

Corylus americana Walt. Hazelnut Map 751

- a. Bracts of fruit united on one side to their summit and partly united on the other side, so that fruit does not appear open. c. *C. AMERICANA* var. *INDEHISCENS*
- a. Bracts of fruit two, distinct and open on both sides to the nut exposing the fruit. b
- b. Branches, leaf-stalks (petioles), and involucre around flower or fruits with gland-tipped hairs a. *C. AMERICANA* var. *AMERICANA* f. *AMERICANA*
- b. Branches, leaf-stalks, and involucre around flowers or fruits without gland-tipped hairs
- b. *C. AMERICANA* var. *AMERICANA* f. *MISSOURIENSIS*

a. *Corylus americana* var. *americana* f. *americana* Map 751

Corylus americana Walt. [G, BB, P & S]
Flowers February-April.

Occurs in dry or moist thickets, woodland, and border of woodland, in valleys and upland. Throughout Missouri and doubtless in every county.

Ranges from Maine to Saskatchewan, south to Georgia, Arkansas, and Oklahoma.

- b. *Corylus americana* var. *americana* f. *missouriensis* (A. DC.) Fern. Map 751
Corylus americana f. *missouriensis* [G, P & S, Steyererm.]
Frequent in the state, but records of its occurrence are less common than f. *americana*.
Occurs in the range of the typical form.

- c. *Corylus americana* var. *indehiscens* Palmer & Steyererm. Map 751
Known from Bollinger, Butler, Jackson, Johnson, Jasper, and Newton counties, but to be expected in other sections of the state.
Ranges from North Carolina to Missouri, Arkansas, and Oklahoma.

Material at one time identified as *Corylus cornuta* Marsh. is now referred to this variety.

The nuts of *C. americana*, if they can be collected before eaten first by blue jays and other birds, are very good and similar to the European filbert. A meal ground from the nuts can be made into a bread of similar type to that made from filberts. The foliage is quite striking in autumn, becoming quite varied. It may be dull orange with brick-red and dull green at

Plate no. 134. 1. *Carya ovalis*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{2}{7}$. 2. *Carya texana* var. *texana*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{2}{7}$. 3. *Corylus americana*, $\times \frac{2}{7}$; a. PLATE NO. 134

the same time or dull purple-red or with combinations of rose, orange, yellow, and pale green.

Excluded Species

Corylus cornuta Marsh. Beaked Hazelnut

This was included by Palmer & Steyermark in their

Annotated Catalogue on the basis of a specimen from Butler County. This is now found to be referable to *C. americana* var. *indehiscens* as an extreme form of that variety. Another specimen (Palmer 16422) from Bollinger County, labeled *C. rostrata* [= *C. cornuta*], is also referable to *C. americana* var. *indehiscens*.

2. **Ostrya** Scop. Hop Hornbeam, Ironwood

Ostrya virginiana (Mill.) K. Koch

Hop Hornbeam

Map 752

More frequently called Ironwood in certain sections.

Flowers April-May.

Occurs in usually dry soil on rocky slopes, along bluffs, borders of upland woods, and rarely along streams. Throughout Missouri, and apparently absent from some of the extreme southeastern lowland counties.

Ranges from Nova Scotia to Manitoba, south to Florida, Tennessee, Arkansas, Texas, and northern Mexico.

Missouri material is represented by the following variations:

- a. Young or new branchlets with stalked glands
 - b. *O. VIRGINIANA* var. *VIRGINIANA* f. *GLANDULOSA*
- a. Young or new branchlets without stalked glands b
- b. Young or new branchlets glabrous (without hairs) or very sparsely hairy
 - a. *O. VIRGINIANA* var. *VIRGINIANA* f. *VIRGINIANA*
- b. Young or new branchlets densely hairy
 - c. *O. VIRGINIANA* var. *LASIA*

a. **Ostrya virginiana** var. **virginiana** f. **virginiana**

Map 752

Ostrya virginiana (Mill.) K. Koch [G, BB, P & S]

This is the most common form encountered in the state.

b. **Ostrya virginiana** var. **virginiana** f.

glandulosa (Spach) Macbr.

Map 752

Ostrya virginiana f. *glandulosa* (Spach) Macbr. [G, Steyermark.]

Ostrya virginiana var. *glandulosa* (Spach) Sarg. [P & S]

Scattered within the range in Missouri in Clark, Clinton, Jackson, and Jasper counties.

c. **Ostrya virginiana** var. **lasia** Fern. Map 752

Frequent throughout the state, but less common than var. *virginiana*.

Ranges from Florida to Texas, north to Massachusetts, Tennessee, Illinois, Iowa, and South Dakota.

The wood of Hop Hornbeam ranks among the hardest and strongest of woods known in eastern North America. It is harder than oak, hickory, locust, or persimmon, and surpassed only by flowering dogwood. The limited size and diameter of the tree, however, makes it useful only for such small-sized articles as tool handles, ax handles, mallets, and for fence posts.

3. **Carpinus** L. Hornbeam, Blue Beech

Carpinus caroliniana Walt. Blue Beech Map 753

Flowers April-May.

Occurs on north-facing bluffs, in rich woods at the base of bluffs, rocky slopes along streams, ravine bottoms, low wooded valleys, and moist woodland.

Two variations may be recognized:

Rare type, known only from Dunklin County; leaves oblong, acute, 1-3.5 (rarely 4) cm. broad, 2.5-8 cm. long, with broad low teeth rarely 1 mm. high; fruiting bracts blunt or pointed, entire (without teeth) or with 1-2 blunt teeth

a. *C. CAROLINIANA* var. *CAROLINIANA*

Common type, throughout eastern Mo., the

Ozarks, and elsewhere; leaves oval or narrowly, abruptly long-tipped, 2.5-6 cm. broad, 5-12 cm. long, with sharp slender teeth up to 1-3 mm. high; fruiting bracts acute, usually with 1-5 sharp teeth b. *C. CAROLINIANA* var. *VIRGINIANA*

a. **Carpinus caroliniana** var. **caroliniana**

Map 753

Carpinus caroliniana Walt. [G, Steyermark., BB in part, P & S in part]

Known only from low woods in Dunklin County, southeastern Missouri.

Ranges from Florida to Texas, north to Maryland, Tennessee, Illinois, and southeastern Missouri.

754 *Betula nigra* (River Birch)755 • *Alnus serrulata* var. *serrulata* f. *serrulata* (Alder)
755 □ *Alnus serrulata* var. *serrulata* f. *novaboracensis*756 • *Fagus grandifolia* var. *caroliniana* f. *caroliniana* (Beech)
756 x *Fagus grandifolia* var. *caroliniana* f. *mollis*

b. *Carpinus caroliniana* var. *virginiana* (Marsh.)
Fern.

Map 753

Carpinus caroliniana in part [of BB, P & S], not Walt.
Eastern Missouri, Ozark region west to Cooper, Morgan, Benton, Hickory, Polk, and McDonald counties, and northwest along the Missouri River locally to Buchanan County.

Ranges from New England to Ontario and Minnesota, south to North Carolina, Tennessee, and Arkansas.

In fall the foliage turns an orange russet with brick-red flushed with greenish, or is dull yellow to pale greenish-yellow. The sapwood is nearly white, and is used for levers, tool handles, and other small articles. The blue-gray fluted stems have a sculptured appearance, resembling twisted muscles. The nuts may be eaten, but, considering their small size, a considerable number would have to be gathered to be of much food value.

4. *Betula* L. Birch

Betula nigra L. River Birch

Map 754

Also called Red Birch.

Flowers April–May.

Occurs in alluvial ground along streams and borders of gravel beds. Nearly throughout Missouri, absent in the extreme northwestern and west-central sectors.

Ranges from Florida to Texas, north to New Hampshire, New York, Pennsylvania, West Virginia, Ohio, Michigan, Wisconsin, Minnesota, and Kansas.

The foliage turns a pale to rich yellow in autumn. Large quantities of pollen are shed by this and other species of birch and constitute one of the important tree pollens in causing hay fever. The wood is used for pulp in papermaking and employed principally in

the manufacture of furniture and woodenware. It is used for shuttles, but not to as much extent as *Cornus florida*, the Flowering Dogwood. At one time it was used for ox yokes and wooden shoes. Along Missouri streams this species germinates along the silty sands and gravels washed with mud deposited by the river and is one of the pioneer species in building up a new forest along stream bank alluvium. Following close behind the initial stages started on pure gravel beds by Vernal Witch Hazel (*Hamamelis vernalis*) and Ward's Willow (*Salix caroliniana*), River Birch, Sycamore, Green Ash, and Silver Maple continue the forest succession as finer sandy alluvium is built up along the river bed and banks.

5. *Alnus* B. Ehrh. Alder

Alnus serrulata (Ait.) Willd. Common Alder

Also called Smooth Alder, Tag Alder. Map 755

Flowers March–April.

Occurs along stream banks, springs, spring branches, and in wet spring-fed meadows. Ozark region north along the Mississippi River to Lewis County.

Ranges from Florida to Louisiana, north to Nova

Scotia, Maine, New Hampshire, Vermont, New York, West Virginia, Ohio, Indiana, Illinois, Missouri, and Oklahoma. Missouri material is represented by the following variations:

Lower surface of fully grown leaves glabrous or nearly so. . . a. *A. SERRULATA* var. *SERRULATA*

f. *SERRULATA*

Lower surface of fully grown leaves densely and permanently short-hairy, velvety to touch . . .

b. *A. SERRULATA* var. *SERRULATA* f. *NOVABORACENSIS*

a. *Alnus serrulata* var. *serrulata* f. *serrulata*

Map 755

Alnus rugosa of auth. in part [P & S, Steyerml.], not (DuRoi) Spreng.

Alnus serrulata (Ait.) Willd. [G, BB]

This is the common type found in the state.

b. *Alnus serrulata* var. *serrulata* f. *novaboracensis* (Britt.) Fern.

Map 755

Alnus serrulata f. *novaboracensis* (Britt.) Fern. [G]

Occasionally found in parts of the Ozark region. Found throughout the range of var. *serrulata*.

The foliage remains dark green for well into autumn after many of the other species have turned color. The leaves stay dark green, finally becoming tinged with dull brown. The presence of this alder indicates boggy ground, usually the location of a spring or spring-fed stream. Associated with this habitat are to be found many rare and unusual species in Missouri.

Fam. FAGACEAE (Beech Family)

- a. Buds long, slender, and pointed, at least 4 times as long as broad; leaves as thin as tracing or onion-skin paper; male flowers in rounded head-like or globe-shaped masses; nuts sharply triangular . . . 1. FAGUS
- a. Buds less than 4 times as long as broad, not long, slender, and pointed; leaves thicker and firmer; male flowers in long narrow catkins; nuts rounded or flattened on one side, not sharply triangular. . . b
- b. Male catkins upright or spreading, pleasantly fragrant; young female flower and fruit covered with prickles; female flowers 2-4 in each involucre; nuts flattened on one side or compressed; fruit a prickly bur . . . 2. CASTANEA
- b. Male catkins drooping or hanging, not fragrant; young female flower not prickly; female flower solitary; nuts with curved or rounded sides; fruit an acorn . . . 3. QUERCUS

1. *Fagus L.* Beech

Fagus grandifolia Ehrh. Beech

Map 756

Flowers April-May.

Occurs in usually acid soils overlying sands, gravels, or clays of Crowley Ridge or on sandstone formations, in rich woods of ravines, slopes, and small valleys bordering streams and spring branches. Southeastern Missouri, mostly on Crowley Ridge in Dunklin, Butler, Stoddard, and Scott counties, and northeast on St. Peter sandstone substrata to Perry County.

Missouri material may be referred to the following variations:

Lower surface of fully grown leaves glabrous (without hairs) . . . a. *F. GRANDIFOLIA* var. *CAROLINIANA*

f. *CAROLINIANA*

Lower surface of fully grown leaves soft-hairy . . .

b. *F. GRANDIFOLIA* var. *CAROLINIANA* f. *MOLLIS*

a. *Fagus grandifolia* var. *caroliniana* (Loud.)

Fern. & Rehd. f. *caroliniana*

Map 756

Fagus grandifolia var. *caroliniana* (Loud.) Fern. [G, BB, P & S, Steyerml.]

This is the more commonly encountered variation in Missouri.

Ranges from Florida to Texas, north to Massachusetts, Ohio, Indiana, Illinois, and Missouri.

b. *Fagus grandifolia* var. *caroliniana* f. *mollis*

Fern. & Rehd.

Map 756

Scattered throughout the range of f. *caroliniana* in Missouri.

Found throughout the range of var. *caroliniana* f. *caroliniana*.

The pollen of the Beech plays only an insignificant role in causing hay fever. The foliage turns a clear yellow in autumn contrasting with the beautiful smooth gray bark. The sweet edible nuts vary in abundance, about every third year reaching a maximum of harvest. They are also a favorite food of hogs

Plate no. 135. 1. *Betula nigra*; Details from Small, The New York Botanical Garden. 2. *Alnus serrulata* var. *serrulata*, $\times \frac{2}{7}$; a. Fruiting branch; b. Flowering branch; Details from Small, The New York Botanical Garden. 3. *Fagus grandifolia*; a. *Fagus grandifolia* var. *caroliniana*, flowering branch, $\times \frac{2}{7}$; b. *Fagus grandifolia* var. *caroliniana*, fruit, $\times \frac{2}{7}$; c. *Fagus grandifolia* var. *caroliniana*, leaf, $\times \frac{2}{7}$; d. *Fagus grandifolia* var. *grandifolia*, leaf, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 4. *Castanea ozarkensis*, $\times \frac{2}{7}$. 5. *Castanea dentata*, $\times \frac{2}{7}$; a. Fruiting branch; b. Nut; Details from Small, The New York Botanical Garden.

PLATE NO. 135

in those areas where open range is permitted. The young unfolding leaves may be cooked as a vegetable. Beech oil, extracted from the nuts of the European Beech, *F. sylvatica*, serves as a table oil in France and other countries and is said to be similar in delicacy to olive oil. Roasted beech nuts are sometimes used as a coffee substitute.

The wood is not very durable. A small amount is used as pulp for papermaking. At one time the wood was largely used for fuel. Although beech wood enters into the manufacture of some furniture, such as chairs, and in flooring, most of the wood is employed for tool handles, shoe-lasts, railroad ties, boxes, barrels, and such articles as clothespins, picnic plates, and spoons.

Although one of the most handsome and stately trees in North America, native beech is rarely used as a shade or ornamental tree, because it not only is

difficult to transplant, but responds poorly to cultivation.

Excluded variety

Fagus grandifolia* Ehrh. var. *grandifolia

Fagus grandifolia Ehrh. [G, P & S, Steyermark.]

This variety, distinguished from var. *caroliniana* by its thinner leaves, which are more narrowed or cuneate at the base, more coarsely and distinctly toothed, and with the prickles of the mature fruit longer, 4–7 mm., instead of 3 mm. or less long, occurs from Nova Scotia and New Brunswick to Ontario and Minnesota, south to Virginia and West Virginia.

Records in Missouri previously referred to this variety are now included under var. *caroliniana*.

2. ***Castanea* Mill. Chestnut**

Lower surface of fully grown leaves glabrous (without hairs) and pale green; spines of fruit glabrous (without hairs); each fruit with usually 2 or 3 nuts, flattened on 1 or 2 sides; cultivated or escaped from cultivation 1. *C. DENTATA*

Lower surface of fully grown leaves minutely hairy and yellowish-cream or whitish; spines of fruit with hairs; each fruit with only 1 nut not flattened; native tree of southwest Missouri 2. *C. OZARKENSIS*

1. ***Castanea dentata* (Marsh.) Borkh.**

Chestnut Map 757
Flowers late May–July.

At one time ranged from Maine and Massachusetts to New York to Ohio, Michigan, Indiana, and southern Illinois, south to Georgia, Alabama, and Mississippi. Apparently now extinct in Florida.

Formerly more planted on farms, woodlots, and around buildings. Sometimes trees planted away from cultivation have persisted in wild or semiwild areas, and specimens from these trees have been collected in Crawford (*Steyermark 63074*) and Howell (*Steyermark 23586*) counties. The Crawford County trees, originally four in number, grew in a dry open pastured slope in a small valley, and were not near any dwellings. Sixty feet or more tall with a spread of a hundred feet, they produced an abundance of fruit, and at the time of the author's original visit in 1936, and again in 1945, showed no sign of the chestnut blight disease. On his last visit to this station, on October 28–29, 1945, along a branch of Crooked Creek near the Dent County line, T₃₅N, R₄W, sect. 35, 2½ miles northeast of Sligo, only one of the trees was still surviving. Seeds from the healthy trees taken to the author's wild flower preserve in northern Illinois and germinated there, beginning in 1946, flowered for the first time eleven years later although

they were only 5 feet tall at that time.

The Howell County record, based on *Steyermark 23586*, from upland woods on top of a dry ridge bordering a field, T₂₇N, R₁₀W, sect. 4, 5 mi. southwest of Willow Springs, July 23, 1937, was collected from one of three large trees occurring with pine, Scarlet Oak (*Quercus coccinea*), Black Oak (*Q. velutina*), and other oaks and hickories, and appearing almost as if native.

Trees which have been planted in various parts of the state are known from the following records collected from the cultivated tree: Nodaway Co. (Northwest Missouri State College at Maryville, *Singleton 118*), Clay Co. (on Rust farm by spring near stream, at Liberty, *Hurst 70*), and Clark Co.

Although nearly wiped out by the chestnut blight, many sections where it originally thrived as tall forest trees still have living trees which send up stump sprouts which survive for a number of years until killed by the disease or occasionally grow to larger specimens which seem to resist the disease. Many dead trees continue to supply a market for chestnut rail fence poles and posts. The wood is used as pulp in papermaking and is also used for railroad ties, cheaper types of furniture, and interior trimming for houses. The bark has been much used in tanning.

Home owners and horticulturists are now planting

757 *Castanea dentata* (Chestnut)758 *Castanea ozarkensis* (Ozark Chinquapin)759 • *Quercus alba* f. *alba* (White Oak)759 □ *Quercus alba* f. *latiloba*759 x *Quercus* X *Bebbiana* (*Quercus alba* X *macrocarpa*)759 † *Quercus* X *Jackiana* (*Quercus alba* X *bicolor*)

other kinds of chestnuts for nut and ornamental trees, such as the Chinese Chestnut (*C. mollissima*) and hybrid races which show more or less immunity to this disease.

2. ***Castanea ozarkensis*** Ashe Ozark Chinquapin
Also called Ozark Chestnut. Map 758
Flowers late May-June.

Occurs in acid soils of dry upland ridges in oak-hickory forest, in southwestern Missouri, in Stone, Barry, McDonald, and Newton (*Palmer* 56575, along Indian Creek, 3½ mi. southeast of Christopher) counties; locally east in Howell County on upland low slopes along small draw in abandoned thicket, 1 mi. southeast of Moody, August 11, 1934, *Steyermark* 14398).

Ranges from Missouri and Arkansas to Oklahoma. Louisiana and Mississippi are sometimes mentioned as in the range of this species, but specimens examined from those states have proved to be *C. pumila* (L.) Mill.

This tree reaches a height of about sixty-five feet in its Missouri habitat, where it usually occupies the upper reaches of ravines and narrow crests of stony chert or flint ridges where the soil is acid and noncalcareous and with a good accumulation of leaf mold. Here it is associated with Sour Gum (*Nyssa sylvatica* var. *caroliniana*), Flowering Dogwood, White Oak, Blackjack Oak, Post Oak, Black Oak, Ozark Hickory (*Carya texana*), Mockernut, and Shagbark Hickory. On the forest floor at its base grow Blueberry (*Vaccinium vacillans* var. *crinitum*), Deerberry (*V. stamineum* and var. *neglectum*), and Farkleberry (*V. arboreum* var. *glaucescens*), along with many other kinds of acid-soil plants.

The leaves are similar to, and may be at first

mistaken for those of, *Quercus Muehlenbergii*, the Chinquapin Oak, but the margins are more sharply toothed and the leaf has a rich yellow- or grass-green on its upper surface instead of the blue-green or dull green of the oak. The Chinquapin Oak also occurs in limestone and calcareous soils.

The mature nuts of the Ozark Chinquapin, like those of the eastern *C. dentata*, are sweet and valued as food. They are smaller than the Eurasian species, *C. sativa*, but have a good flavor. The nut of the Eurasian species has served as an important bread source, often being substituted for potatoes or wheat; it has also been cooked as a starchy vegetable dish or used as a flour for soups. The French, especially, use chestnuts to a greater extent in their cookery than people of other countries, even to the degree of extracting sugar from the nuts. *Marrons glacés*, sometimes seen on restaurant menus or sold in grocery stores, are chestnuts which have been first boiled, afterwards placed in sugar, and then dried. The eastern American Chestnut, *C. dentata*, was used by the early colonists in their soups and as starchy vegetables, and the American Indian included the nuts in their corn dough. The nuts were even roasted as a substitute for coffee and chocolate. Although the nuts of the Ozark species have not received any especial attention nor are known to have been used for the several types of dishes mentioned above, it is probable that they could serve in similar preparations if given an opportunity.

So far as known, *C. ozarkensis* has not suffered from attack by the fungus parasite, *Endothia parasitica*, responsible for the chestnut blight disease, but the blight is recorded as occurring in Missouri on various planted trees of the eastern *C. dentata* (see Maneval, W. E. A list of Missouri fungi. Univ. Mo. Stud. 12, no. 3, pp. 3, 100. 1937).

3. *Quercus* L. Oak

In number of species oaks outrank any other group of trees in the forests of Missouri and are also the most important timber trees in the state. The wood of various species is much used for railroad ties, furniture, such as chairs and tables, office desks, interior paneling and veneer, flooring, barrels, wagons, agricultural implements, baskets and novelties, fuel, and charcoal. The bark is rich in tannin and is used for tanning leather.

The wind-blown pollen is very light and abundantly produced by all species. Among trees, more cases of hay fever have been attributed to oaks than to any other kinds of trees. If oak leaves are browsed by cattle to the exclusion of other kinds of food, it is believed that toxic effects result, most cases of poisoning occurring in early spring when other natural growth is less plentiful. The tannic acid itself, found in the leaves, is not believed to cause the poisoning, but rather other substances, which are contained, are believed responsible for any serious trouble which may develop.

In identifying oaks, it must be kept in mind that as many characters as possible, leaves, twigs, winter buds, and fruit, must be taken into consideration. Use of one character alone may lead to difficulties.

Of the three main groups of oaks in Missouri (1) the White Oak group matures its fruit the first and same year the young acorns develop on the newest shoots, the leaves have rounded lobes or teeth without bristly or pin-point tips, the inside of the acorn shell is smooth, the kernel is sweet, and the bark is pale gray; (2) the Black Oak group matures its fruit at the end of the second growing season, fully grown fruit being found only on last year's twigs or the ones previous to the season in which collected, the leaves have bristle or pin-point tips, the inside of the acorn shell is silky-hairy, the kernel is bitter, and the bark is usually blackish or dark gray; (3) the Willow Oak group, to which belong Shingle and Willow Oak, in which the leaves are entire (without teeth or lobes), and the fruit ripens the second year.

Many species of oaks cross with one another, and the following key does not include hybrids. These are mentioned after the description of a species and in a separate list at the end. Since the leaves are best developed after May 1, greater use of the following key will be after that date. If no fruit is available on the branches at the time of collection, it is often possible to find old fruits of last year lying on the ground somewhere around the base of the tree.

- a. No teeth or lobes on margins of leaves (rarely a seedling or young sprout may show some teeth) . . . *b*
- b. Leaves broadest around the middle or of about the same width throughout . . . *c*
 - c. Lower surface of leaves hairy; leaves mainly $2\frac{1}{2}$ –4 times as long as broad, averaging 3–6 cm. wide, rarely narrower; leaf-stalk (petiole) usually hairy; common, in most counties of Missouri . . . 8. *Q. IMBRICARIA*
 - c. Lower surface of leaves mostly glabrous (without hairs) or with some hairiness along the mid-nerve or in the axils of the nerves; leaves mainly 5–8 times as long as broad, usually 0.6–2.5 cm. (rarely to 3) wide; leaf-stalk (petiole) mainly glabrous (without hairs); swamps and low ground of southeast Missouri . . . 9. *Q. PHELLOS*
 - b. Leaves broadest towards the top, enlarged or broadened upward . . . *d*
 - d. Lower surface of leaves hairy; leaves only slightly, if at all, longer than broad, sometimes as wide as long, usually blunt, rounded, or somewhat heart-shaped at base, rarely straight or tapering; lower surface of leaves yellow-brown or yellow-green; cup of fruit more or less top-shaped or inversely conical, 1.5–2 cm. broad . . . 11. *Q. MARILANDICA*
 - d. Lower surface of leaves without hairs (glabrous) or nearly without (glabrate); leaves usually $1\frac{1}{2}$ –2 times as long as broad, tapering to a narrowed, acute, or triangular base; lower surface of leaves pale green; cup of fruit saucer-shaped, 1–1.5 cm. broad . . . 10. *Q. NIGRA*
- a. Teeth or lobes appearing along the margins or near the top of the leaves, or leaves deeply cut. . . *e*
- e. Lobes or teeth of mature leaves lacking bristle-like points, the mid-nerve and side nerves remaining included in leaf tissue (teeth of leaves pointed with short tip in *Q. prinoides* var. *acuminata* and some other species, but not bristle-tipped) . . . *f*
 - f. Lower surface of fully grown leaves without hairs (rarely some hairs along main nerves or in their axils) . . . *g*
 - g. Lower surface of fully grown leaves whitened; leaves usually with 6–10 (rarely 4) lobes; acorn 1.8–3 cm. long; acorn cup with warty or corky scales; common tree throughout Missouri. . . 1. *Q. ALBA*
 - g. Lower surface of fully grown leaves dull or slightly paler green, not whitened; leaves with 2–5 lobes; acorn 0.8–1.6 cm. long; cup with flat unthickened scales; tree of lowlands of southeast Missouri . . . 10. *Q. NIGRA*

- f. Lower surface of fully grown leaves with hairs more or less covering the surface *h*
- h. Margins of leaves wavy or with 3-13 rounded or pointed teeth along each margin, but not lobed; the spaces (sinuses) between the teeth shallow, running less than a third the distance to the main mid-nerve; main side (lateral) nerves of the lower surface of leaves more or less regularly spaced and equally prominent *i*
 - i. Some or most of the side nerves of the lower surface of leaves not ending in the teeth; stalks (peduncles) of fruits 2-6 cm. long, longer than the leaf-stalks (petioles). 5. *Q. BICOLOR*
 - i. All side nerves of the lower surface of leaves ending in the teeth; stalks (peduncles) of fruits none or shorter than the leaf-stalks (petioles), at most 1 cm. long. *j*
 - j. Trees found only in southeastern Missouri north to Cape Girardeau, Bollinger, Madison, and Iron counties; hairs on lower surface of leaves simple and erect or few-branched (use magnifying lens), the leaf surface beneath more or less velvety to the touch; cup of fruit 2.5-3 cm. broad with scales free to the base 6. *Q. MICHAUXII*
 - j. Trees in other parts of Missouri, or also in southeastern Missouri; hairs on lower surface of leaves star-shaped (stellate), the rays spreading out from the center (use magnifying lens), the leaf surface beneath not velvety to the touch; cup of fruit 1-1.5 (rarely 2) cm. broad, only the tips of the scales free or distinct *k*
 - k. Usually low shrub 1-3 m. tall; teeth of leaf mostly 3-8 on each side, sometimes more typically blunt but also pointed or acute; leaves mainly 4-10 cm. long (up to 13 cm.); leaf-stalks (petioles) mainly 5-15 mm. long; western half of Missouri east to Putnam, Sullivan, Macon, Howard, Benton, Dallas, Greene, and Stone counties 7a. *Q. PRINOIDES*
var. *PRINOIDES*
 - k. Usually medium to large tree, 20-30 m. tall, but becoming shrubby and only 2 meters tall; teeth of leaf mainly 8-13 on each side, sometimes 6-7, typically sharp, pointed, and prominent, but varying to blunt, low, and less prominent; leaves mainly 10-20 cm. long; leaf-stalks (petioles) (10)-15-30 mm. long; throughout Missouri in practically every county 7b. *Q. PRINOIDES* var. *ACUMINATA*
- h. Margins of leaves with 1 or more (up to 5) deep lobes projecting from each margin, at least 1 of the spaces (sinuses) prominent and extending more than one-third the distance to the main mid-nerve; main side (lateral) nerves of the lower surface of leaves not equally spaced and not equally conspicuous *l*
 - l. Twigs and branchlets rather densely hairy throughout the season; leaf blades usually with 3-5 main lobes; hairs on lower surface of leaves erect and with only few branches (use magnifying lens); lower scales of cup of acorn flat or somewhat concave; mature nut usually less than 12 mm. in diameter 2. *Q. STELLATA*
 - l. Twigs and branchlets chiefly glabrous (without hairs) at maturity; leaf blades usually with 5-9 main lobes; hairs on lower surface of leaves horizontally spreading and with many branches (use magnifying lens); lower scales of cup of acorn with some thickening or enlargement in the upper part; mature nut more than 12 mm. in diameter *m*
 - m. The deepest space (sinus) of the leaf about half-way up each side divides a generally broader and more shallowly lobed upper portion from a narrower and more deeply lobed lower portion; leaf-blades mainly 10-25 cm. long; upper (inner) scales of cup of acorn prolonged into slender tips, forming a fringe; throughout Missouri, practically in every county 4. *Q. MACROCARPA*
 - m. The spaces (sinuses) of the leaf about half-way up scarcely or not deeper than the other spaces; leaf-blades mainly 10-20 cm. long; upper (inner) scales of cup of acorn acute (short-pointed) or blunt, not prolonged, but sometimes forming a ragged rim around the top not to be mistaken as prolonged awned scales; southeastern Missouri north along Mississippi River to St. Louis County and locally in Taney County 3. *Q. LYRATA*
- e. Lobes or teeth of mature leaves or summit of leaves with bristle-like points projecting (main nerves and side nerves projecting from leaf tissue) *n*
- n. Lower surface of fully grown leaves more or less hairy on some part of surface or over the whole surface *o*
 - o. Lower surface of fully grown leaves with a yellowish, grayish, or whitish hairiness; the individual star-shaped (stellate) hairs so minute that they are barely visible under a 10× magnifying lens; leaves conspicuously drooping or hanging from the branches; scales of cup of acorn with a reddish-brown dark border; nut enclosed by cup about $\frac{1}{3}$ its length; trees of extreme southern and southeastern Missouri 12. *Q. FALCATA*

- o. Lower surface of fully grown leaves with a rusty or brownish hairiness; the individual star-shaped (stellate) hairs large enough to be seen under a 10 × magnifying lens; leaves mostly stiffly erect, ascending, or spreading from the branches; scales of cup of acorn without a dark border; nut enclosed by cup about $\frac{1}{2}$ its length; trees of wide range mostly throughout Missouri. *p*
- p. Leaves mostly fan-shaped or more broadened around top, usually with 3, sometimes 5, broad lobes, other lobes none or poorly developed; fully grown twigs with scattered scurfy hairiness; buds covered with rusty-colored hairs; leaf-stalks (petioles) mostly 10–20 mm. (as little as 4 mm. long or up to 25 mm.); acorns 10–18 (rarely 20) mm. long; cup of acorn 13–20 mm. broad 11. *Q. MARILANDICA*
- p. Leaves usually narrower at the top, broadest around the middle, with usually 5–9 long and narrow or short and broad lobes separated by prominent spaces, the longest lobes along the sides, not at the top; fully grown twigs (except in *f. missouriensis*) mostly without hairs; buds covered with gray or buff hairs; leaf-stalks (petioles) mostly 25–80 mm. long; acorns 15–25 mm. long; cup of acorn 20–25 mm. broad 13. *Q. VELUTINA*
- n. Lower surface of fully grown leaves without hairs, except for small tufts in the main axils where the side nerves join the mid-nerve *q*
- q. Leaves fan-shaped or broadened toward the summit with a generally 3-lobed upper half *r*
- r. Leaves only slightly, if at all, longer than broad, sometimes as wide as long, usually blunt, rounded, or somewhat heart-shaped at base, rarely straight or tapering; lower surface of leaf yellow-brown or yellow-green; leaf-stalks (petioles) mainly 5–15 mm. long; cup of fruit more or less top-shaped or inversely conical, 1.5–2 cm. broad 11. *Q. MARILANDICA*
- r. Leaves usually $1\frac{1}{2}$ –2 times as long as broad, tapering to a narrowed, acute, or triangular base; lower surface of leaf pale green; leaf-stalks (petioles) mainly less than 5 mm. long; cup of fruit saucer-shaped, 1–1.5 cm. broad 10. *Q. NIGRA*
- q. Leaves not fan-shaped or broadened toward the summit, but narrower at the summit and broadest at the middle or toward the base with 5–11 long and narrow or short and broad lobes separated by spaces, the longest lobes near the middle of the leaf *s*
- s. The longest lateral (side) lobes of the leaf shorter than or about equaling to slightly longer than the width of the solid green undivided central part of the leaf *t*
- t. Main midrib on upper surface of leaf usually glabrous (without hairs); leaf-stalks (petioles) glabrous (without hairs) or nearly so; topmost (terminal) winter buds glabrous, chestnut-brown, 3–7 mm. long, not strongly angled; cup of acorn mostly saucer-shaped, with tight, slightly hairy scales; leaf-blades dull, not shining above, rather bluish-green, thin; lower surface of fully grown leaves seldom with conspicuous tufts of hairs at junction of midrib and main side nerves 18. *Q. RUBRA*
- t. Main midrib on upper surface of leaf hairy; leaf-stalks (petioles) partly or completely hairy; topmost (terminal) winter buds gray-hairy, 6–12 mm. long, strongly angled; cup of acorn top-shaped or inversely conical or cup-like, with loosely overlapping hairy scales; leaf-blades shining above, dark green, thick; lower surface of fully grown leaves always with conspicuous tufts of hairs at junction of midrib and main side nerves 13. *Q. VELUTINA*
- s. The longest lateral (side) lobes of the leaf 2–6 times as long as the width of the solid green undivided central part of the blade *u*
- u. Main midrib on upper surface of leaf hairy; leaf-stalks (petioles) partly or completely hairy; upper scales of acorn cup loosely overlapping (imbricated), thin, forming a loose fringe; topmost (terminal) buds gray-hairy, 6–12 mm. long, strongly angled 13. *Q. VELUTINA*
- u. Main midrib on upper surface of leaf usually glabrous (without hairs); leaf-stalks (petioles) glabrous (without hairs) or nearly so; upper scales of acorn cup tight, appressed to one another, thickish, not forming a loose fringe; topmost (terminal) buds 1–7 mm. long, glabrous or hairy *v*
- v. Acorn cup 3–5 mm. high, 1–1.5 cm. broad; nut 10–13 mm. long; fully grown buds very small, 1–5 mm. long; base of many leaves often tapering or often V-shaped. 17. *Q. PALUSTRIS*
- v. Acorn cup higher or broader than noted in alternate v. above; nut 12–26 mm. long; fully grown buds 4–7 mm. long; base of leaves either truncate (straight) or more or less tapering or V-shaped *w*
- w. Scales of cup without hairs, shining, brown or chestnut-colored; trees of the southeastern Ozarks west to Douglas and Howell counties 15. *Q. COCCINEA*
- w. Scales of cup hairy with a silky or appressed hairiness, dull, ashy-gray; trees of northern, or central and southern, or southernmost Missouri *x*

- x. Mature leaves 15–20 cm. long; leaf-stalks (petioles) 4–6 cm. long; cup of acorn saucer-shaped to top-shaped, rounded or flattened at base with a shallow rim, usually enclosing $\frac{1}{4}$ – $\frac{1}{3}$ of nut, 2–3 cm. broad; fully mature buds completely glabrous (without hair) 16. *Q. SHUMARDII*
- x. Mature leaves 7–16 cm. long; leaf-stalks (petioles) 2–5 cm. long; cup of acorn top-shaped to deep cup-shaped, sloping or stalked at base, usually enclosing $\frac{1}{3}$ – $\frac{1}{2}$ of nut, 1–1.8 cm. broad; fully mature buds noticeably hairy or at least slightly hairy on margins of upper scales y
- y. Acorn 12–20 mm. long, usually longer than wide and narrowed at both ends; cup gradually sloping to base; inner bark yellow or orange; shape of tree mostly broadly oblong, not pyramidal; leaves generally broadest at the middle, oblong-obovate, either abruptly narrowed or truncate (straight) at base; known only from Harrison County, northern Missouri. 14. *Q. ELLIPSOIDALIS*
- y. Acorn 20–28 mm. long, oblong-ovoid, scarcely longer than wide, rounded at the ends; cup enclosing $\frac{1}{3}$ – $\frac{1}{2}$ of the acorn, abruptly contracted to a stalk-like base 2–7 mm. long; inner bark not orange nor yellow; shape of tree pyramidal; leaves mostly broadest in upper half, obovate or rhombic-obovate, usually abruptly or narrowly tapering or V-shaped at the base; known only from Butler County, southeastern Missouri 19. *Q. NUTTALLII*

1. ***Quercus alba* L.** White Oak Map 759
Flowers early April–May.

Occurs most frequently on dry upland slopes and ridges and also in low ground of valleys and ravine bottoms. Throughout Missouri, doubtless in every county.

Ranges from Florida to Texas, north to Maine, Quebec, Ontario and Minnesota.

Two variations may be distinguished in Missouri material:

Leaves cut $1/2$ – $3/4$ distance inwardly toward the central mid-nerve, the lobes long and narrow, mostly 8–20 mm. (rarely to 30) broad 1a. *Q. ALBA*
f. *ALBA*

Leaves cut less than half-way to the central mid-nerve, the lobes relatively shorter and broader, mostly 15–30 (up to 40) broad 1b. *Q. ALBA*
f. *LATILOBA*

1a. ***Quercus alba* f. *alba*** White Oak Map 759
This is the common type encountered in Missouri.

1b. ***Quercus alba* f. *latiloba*** (Sarg.) Map 759
Palmer & Steyererm.

Scattered through the range of the commoner type in Missouri, north to Clark, Knox, and Adair counties; not recorded from the northwestern quarter of the state.

Quercus alba is the state tree of Maryland, and is often considered the most valuable species of tree in the United States from the standpoint of the general all-around purposes to which the wood is applied. At one time it was much used in general construction work, but is being replaced by cheaper woods. Early settlers in North America employed the durable wood for their ships, homes, barns, bridges, and mills. Today it is more often used for furniture, interior paneling, railroad ties, agricultural implements, and barrels. It has always been widely used for fuel pur-

poses. Up until recently, the wood was also used for wagons and the bark used for tanning.

This species and other members of the White Oak group have sweet acorns rich in starch and oil, which are eaten by squirrels, hogs, and various other animals. The American Indians prepared a type of pasty bread from some of the species, after first leaching out the bitter qualities of the raw acorns. The foliage of white oak turns a dull rose-red or rose-purplish in fall.

This oak is known to hybridize with several species, and in Missouri three hybrids involving this species are known:

Quercus* × *Bebbiana Schneid. (*Q. alba* × *macrocarpa*) is known from Marion, Jackson, and Cole counties. A tree in Forest Park, in St. Louis County measures 7 feet, 8 inches in circumference, has a height of 62 feet and a spread of 77 feet, and is claimed to represent the largest tree recorded for this hybrid oak.

Quercus* × *Fernowi Trel. (*Q. alba* × *stellata*) is known from St. Louis and Dade (Palmer 54717) counties.

Quercus* × *Jackiana Schneid. (*Q. alba* × *bicolor*) is known from Lafayette Co.

2. ***Quercus stellata*** Wang. Post Oak Map 760
Flowers April–May.

Occurs mostly in dry or rocky upland woods and glades, and sometimes along small streams. Common throughout Missouri; not recorded from a few extreme northwestern counties.

Missouri material is represented by two principal variations:

Lower surface of leaves noticeably hairy; leaves mainly 10–20 cm. long; main side lobes of leaves horizontally spreading, large, broadened toward summit, narrowed or constricted at base, truncate

760 • *Quercus stellata* var. *stellata* (Post Oak)
 760 □ *Quercus stellata* var. *Margaretta*
 760 x *Quercus Fernowii* (*Quercus alba* X *stellata*)

761 • *Quercus lyrata* f. *lyrata* (Overcup Oak)
 761 □ *Quercus lyrata* f. *viridis*
 761 x *Quercus* X *Sterrettii* (*Quercus stellata* X *lyrata*)

762 • *Quercus macrocarpa* f. *macrocarpa* (Bur Oak)
 762 □ *Quercus macrocarpa* f. *oliveaeformis*
 762 x *Quercus* X *Deamii* (*Quercus macrocarpa* X *prinoides* var. *acuminata*)

(as if cut straight across) or emarginate (shallowly notched or sunken in the center) at the summit; common type . . . 2a. *Q. STELLATA* var. *STELLATA* Lower surface of leaves nearly without hairs or only sparsely hairy; leaves shorter, 4–10 cm. long; lobes ascending or spreading, entire (without notches or toothings), not constricted or narrowed at the base; rare and known only from southwestern Missouri. 2b. *Q. STELLATA* var. *MARGARETTA*

2a. ***Quercus stellata* var. *stellata*** Map 760

The common variety, throughout the state, except not recorded from a few extreme northwestern counties.

Ranges from Florida to Texas, north to Massachusetts, New York, Pennsylvania, Ohio, Indiana, Illinois, Iowa, and Kansas.

2b. ***Quercus stellata* var. *margaretta*** (Ashe)

Sarg. Map 760
Quercus margaretta Ashe [BB]

Known only from Jasper (near Prosperity) and Lawrence (open woods with limestone outcrops above bluff, $\frac{1}{2}$ mi. southeast of Sycamore School, Lincoln Township, September 20, 1950, *Palmer 51154*) counties.

Ranges from Florida to Texas, north to Virginia, locally to Massachusetts, Missouri, and Oklahoma.

Various other varieties have been described but are not usually recognized.

The foliage of Post Oak in fall turns to an orange-brown or chestnut-brown. The wood is somewhat tougher than White Oak and is chiefly used for railroad ties, but also for fencing, fuel, and construction. It is often associated with Black Jack Oak (*Q. marilandica*) on the poorer and more acid upland soils and rocks, frequently in cherty, sandstone, and granite areas.

Quercus stellata hybridizes with a few other species, of which three others are involved in Missouri:

Quercus* X *Fernowii Trel. (*Q. alba* X *stellata*), referred to under *Q. alba*.

Quercus* X *stelloides Palmer (*Q. prinoides* var. *prinoides* X *stellata*), known from Putnam and Jackson counties.

Quercus Sterrettii Trel. (*Q. lyrata* X *stellata*), known from a questionable sterile specimen from Carter County (along Current River, near Van Buren, May, 1945, *Bill Bauer*, in herb. Chi. Nat. Hist. Mus.).

3. ***Quercus lyrata*** Walt. Overcup Oak Map 761
 Flowers early April–May.

Occurs in alluvial or wet ground in low or swampy woods in the valleys of streams and bayous, most frequently encountered in southeastern Missouri, extending north along the Mississippi and Meramec river bottoms and flood plain forests to St. Louis County, and a local stand formerly along Long Creek in Taney County, southwestern Missouri.

Ranges from Florida to Texas, north to New Jersey along the coastal plain, inland north to Indiana, Illinois, Iowa, and Missouri.

Missouri material is represented by two variations:

Lower surface of leaves whitened, the hairs usually dense 3a. *Q. LYRATA* f. *LYRATA*
 Lower surface of leaves green, the hairs scattered, not dense 3b. *Q. LYRATA* f. *VIRIDIS*

3a. ***Quercus lyrata* f. *lyrata*** Map 761
Quercus lyrata Walt. [G, BB, P & S]

This is less common than the other variation.

3b. ***Quercus lyrata* f. *viridis*** Trel. Map 761
 Apparently f. *viridis* is the more common form in Missouri.

A remarkable isolated stand of this oak occupied a natural swamp in an old creek meander of Long Creek, tributary to White River, T21N, R22W,

sect. 3, 1½ mi. north-northwest of Oasis (Cedar Valley), 9 mi. southwest of Branson, in Taney County (*Steyermark* 80729, and collections by *Moore & Iltis* and *Palmer*), and was dominant at this locality. This relict area, which also contained a remnant flora of such other coastal plain and Mississippi Embayment species as *Trachelospermum difforme*, was in existence until 1956, when the impounded waters of the Table Rock Dam on White River turned the station into part of the new lake bottom.

The foliage of this species turns in autumn an orange mixed with brown and green, or sometimes more red and yellow are combined with the orange. The wood is employed similarly to that of White Oak.

Quercus lyrata hybridizes with a few other species, of which the following two are involved as hybrids in Missouri:

Quercus* × *humidicola Palmer (*Q. bicolor* × *lyrata*), known from Dunklin County (Campbell, October 6, 1910, *Bush* 6365, holotype).

Quercus* × *Sterrettii Trel. (*Q. lyrata* × *stellata*), referred to previously under *Q. stellata*.

4. ***Quercus macrocarpa*** Michx. Bur Oak Map 762

Also called Mossy Cup Oak.
Flowers early April–May.

Occurs usually in low woods or slopes in valleys along streams, especially in the Ozark section, but in glaciated northern Missouri often in upland woods and on higher slopes, as well as in valleys. Throughout Missouri, and doubtless in every county.

Ranges from New Brunswick, Maine, and Quebec to Manitoba, south to Maryland, Alabama, Louisiana, Arkansas, Oklahoma, and Texas.

Missouri material is represented by two variations:

The broad upper portion of leaf with relatively short and broad, oblong or ovate, blunt lobes; cup of acorn covering 2/3 of the acorn; acorn flat at base, oblong to ovoid, about 2/3 as thick as long

4a. ***Q. MACROCARPA*** f. ***MACROCARPA***

The broad upper portion of leaf with relatively narrower and longer lobes; cup of acorn covering only 1/3–1/2 of the acorn; acorn strongly rounded at base, oval, about 1/2 as thick as long . . .

4b. ***Q. MACROCARPA*** f. ***OLIVAEFORMIS***

4a. ***Quercus macrocarpa*** f. ***macrocarpa*** Map 762

Quercus macrocarpa Michx. [G, P & S, Steyermark]
Quercus macrocarpa var. *macrocarpa* [BB]

This is the common form encountered in Missouri.

The fruit is quite variable, both in size of acorn, cup, and length and fringing of scales of the cup.

4b. ***Quercus macrocarpa*** f. ***olivaeformis*** (Michx. f.) Trel. Map 762 *Quercus macrocarpa* var. *olivaeformis* (Michx. f.) Gray [BB, P & S, Steyermark.]

Known only from Atchison (*Palmer* from Watson, September 4, 1920) and Linn counties in northern Missouri.

The branches of younger trees of the Bur Oak generally develop corky wings which are mostly absent on the older trees. The autumnal coloring of this oak is one of the least colorful of the genus, turning to a dull yellow or greenish-yellow and brown combination. Among the species of oaks, the trunk of this one attains the greatest diameter in Missouri, the Big Oak State Park in Mississippi County possessing the largest tree known in the state. Only the base of the tree now remains to testify to its once former great size, as it was severely damaged a number of years ago by storms. Its circumference 4½ feet above the ground measures 21 feet 4 inches, and before the damage occurred, the tree had a height of 143 feet, and a spread of 114 feet. This tree is estimated to have been at least 400 years old. The tap root of the Bur Oak is comparatively short in comparison with the widespreading branches above ground.

The wood of Bur Oak is used similarly to that of White Oak, and has been used in general construction work, furniture, barrels, shipbuilding, agricultural implements, railroad ties, fences, and for fuel.

Quercus macrocarpa hybridizes with a few other species, of which the following three are involved as hybrids in Missouri:

Quercus* × *Bebbiana Schneid. (*Q. alba* × *macrocarpa*), previously accounted for under *Q. alba*.

Quercus* × *Deamii Trel. (*Q. macrocarpa* × *Q. prinoides* var. *acuminata* [*Muehlenbergii*]) Deam Oak
Quercus × *fallax* Palmer [G]
Quercus × *Hillii* [of BB, P & S, Steyermark., Deam], not Trel.

Known from Holt, Clinton, Jackson, and Greene counties.

The name *Quercus* × *Deamii* has been misapplied. The reader is referred to Dr. H. H. Bartlett's discussion of this hybrid (Rh. 53: 249–64. 1951) for more details. He has submitted evidence to show that it represents a cross between *Q. macrocarpa*, the Bur Oak, and *Q. prinoides* var. *acuminata* [*Muehlenbergii*], the Chestnut Oak, instead of, as originally thought and recorded in the literature, a cross between *Q. alba*, the White Oak,

763 • *Quercus bicolor* (Swamp White Oak)
 763 □ *Quercus* × *Hillii* (*Quercus bicolor* × *macrocarpa*)
 763 × *Quercus* × *humidicola* (*Quercus bicolor* × *lyrata*)

764 *Quercus Michauxii* (Basket Oak)

765 • *Quercus prinoides* var. *prinoides* (Dwarf Chestnut Oak)
 765 □ *Quercus* × *stelloides* (*Quercus prinoides* var. *prinoides* × *stellata*)

and *Q. prinoides* var. *acuminata* [*Muehlenbergii*]. Bartlett based his conclusions on progeny tests. Mr. E. J. Palmer believes, however, that the Deam Oak is a cross between *Q. alba* and *Q. bicolor*, judging by a tree grown at Arnold Arboretum from an acorn sent by Deam from the original tree.

Quercus* × *Schuettei Trel. (*Q. bicolor* × *macrocarpa*)
Quercus × *Hillii* Trel. [G]

Known only from St. Clair County (low alluvial woods along Monegaw Creek near Monegaw Springs, October 3, 1936, *Steyermark 20216*).

5. ***Quercus bicolor*** Willd. Swamp White Oak
 Map 763

Flowers early April–May.

Occurs in alluvial and rich soils of low woods in valleys and on slopes, in wet ground bordering swamps and oxbow lakes of flood plain and stream meanders, and along streams. Common in northern, central, and most of eastern Missouri, south to Wayne, Reynolds, Crawford, Laclede, St. Clair, and Cass counties, locally in Taney County along White River; absent from much of the unglaciated prairie and Ozark sections, and from the southeastern lowland area.

Ranges from Maine and Quebec to Minnesota and Nebraska, south to Georgia, Kentucky, Tennessee, Arkansas, and Oklahoma.

This species has longer stalks (peduncles) supporting the fruit than that of any other native species of oak in Missouri, and, among the species with which it might be confused, only the cultivated English Oak (*Q. robur* L.) has as long or longer peduncles (from 3–8 cm. long). The base of the leaf of *Q. bicolor* is rounded or wedge-shaped, while that of *Q. robur* is auricled with rounded projections. The silvery-white lower surface of the leaves is quite conspicuous in *Q. bicolor*, and, when the wind blows through the

foliage, this paler side of the leaf is quickly visible.

The wood of this species is not distinguished commercially from that of White Oak, and is employed for construction, furniture, interior finish, shipbuilding, barrels, railroad ties, and fuel.

Quercus bicolor is known to hybridize with a few other species, involving the following three hybrids in Missouri:

Quercus* × *humidicola Palmer (*Q. bicolor* × *lyrata*), previously referred to under *Q. lyrata*.

Quercus* × *Jackiana Schneid. (*Q. alba* × *bicolor*), previously referred to under *Q. alba*.

Quercus* × *Schuettei Trel. (*Q. macrocarpa* × *bicolor*), previously referred to under *Q. macrocarpa*.

6. ***Quercus Michauxii*** Nutt. Basket Oak
 Map 764

Also called Cow Oak, Swamp Chestnut Oak
Quercus Prinus of some authors [P & S, Steyermark, Deam], not L.

Flowers early April–May.

Wet low woods in depressions and valleys, along bayous and slow streams principally in the lowland section of southeastern Missouri, north to Cape Girardeau, Bollinger, Madison, and Iron counties, and west to Wayne and Ripley counties.

Ranges from Florida to Texas, north to New Jersey, Indiana, Illinois, and Missouri.

This species has very large acorns, compared with some other oaks in Missouri, varying from 2.5–3.5 cm. long and 2–3 cm. thick, with cups 2–3 cm. broad. The tree is a handsome one with large rounded summit. The bark is conspicuous because of its silvery white or light gray color, and forms a striking contrast in autumn when the foliage turns a crimson or dark red color. Because the wood naturally splits into long, narrow, tough sections, splints from it were widely

used in the southern states for baskets for carrying cotton, and, when woven, make satisfactory chair bottoms. Other uses for which it has served are agricultural implements, wheels and axles, other parts of wagons, railroad ties, barrel staves, furniture, cant-hooks used in lumbering, fences, and fuel. *Quercus Michauxii* is also a source of tannin.

The name Cow Oak originates from the fact that cows frequently eat the acorns of this species in the southern states. The kernels contain less bitterness than is found in any other of the oak group, and are sufficiently sweet to eat raw.

Although the species is known to hybridize with White Oak (*Q. alba*) and Bur Oak (*Q. macrocarpa*), no hybrids have been found in Missouri involving these species and *Q. Michauxii*.

7. ***Quercus prinoides* Willd.** Map 765

This has usually been treated as distinct from *Q. Muehlenbergii*. However, during the past two decades much more opportunity to observe these oaks in the field has made it evident that they intergrade and are not readily separated as species. They seem more naturally maintained as varieties, and are so treated in the present work, following Gleason's similar treatment in the *New Britton and Brown Illustrated Flora*. Differences between the two have been presented in the general key to *Quercus*.

7a. ***Quercus prinoides* Willd. var. *prinoides***

Dwarf Chestnut Oak Map 765
Also called Scrub Oak, Dwarf Chinquapin Oak
Quercus prinoides Willd. [G, Deam, P & S, Steyererm.]
Flowers April–May.

Occurs in dry exposed soils in open woods, glades, along bluffs, open banks along roadsides, thickets, and borders of upland woods and prairies. Western half of Missouri, mainly in the glaciated and unglaciated prairie sections, east to Putnam, Sullivan, Macon, Howard, Benton, Hickory, Dallas, Greene, and Stone counties. Previous records from St. Louis, Shannon, and Howell counties are now referred to *Q. prinoides* var. *acuminata*.

Ranges from Maine to Minnesota and Nebraska, south to Virginia, Alabama, Tennessee, Arkansas, Oklahoma, and Texas.

Quercus prinoides var. *prinoides* is very distinct in its extreme form as a low spindly-branched bush frequently forming patches only a few feet high with slender twiggy branches, small leaves mostly 5–10 cm. long with 3–7 low blunt teeth on each margin, and small acorn cups 1–1.5 cm. broad covered with small tubercled scales. Unfortunately, many plants are

found which approach or grade into *Q. prinoides* var. *acuminata* (*Q. Muehlenbergii*), not only as small trees, but with longer leaves with 8–10 teeth which may be low and blunt, or prominent and as pointed as in characteristic *Q. prinoides* var. *acuminata*.

In Missouri *Q. prinoides* var. *prinoides* hybridizes with only one species, *Q. stellata*:

***Quercus* × *stelloides* Palmer** (*Q. prinoides* var. *prinoides* × *Q. stellata*), known from Sullivan and Jackson counties, and previously referred to under *Q. stellata*.

Another hybrid involving this species and White Oak (*Q. alba*) has not been recorded from Missouri.

7b. ***Quercus prinoides* var. *acuminata* (Michx.)**

Gl. Chestnut Oak Map 765a
Also called Yellow Oak, Chinquapin Oak
Flowers April–May.

Most frequently found in limestone rocky areas on bluffs or borders of glades and upland woods, and also in alluvial ground in valleys along streams or at the base of limestone bluffs or slopes. Throughout Missouri, absent only in two counties in extreme south-eastern Missouri.

Two forms are encountered in Missouri:

Leaves oblong or lanceolate, mostly 2.5–8.5 cm. broad, typically with rather prominent sharply pointed teeth . . . 7b. *Q. PRINOIDES* var. *ACUMINATA*
f. *ACUMINATA*

Leaves obovate to obovate-oblong, mostly 9–15 cm. broad, typically with less prominent, shorter and broader teeth . . . 7c. *Q. PRINOIDES* var. *ACUMINATA*
f. *ALEXANDERI*

7b. ***Quercus prinoides* var. *acuminata* f. *acuminata***

Map 765a
Quercus prinoides var. *acuminata* (Michx.) Gl. [BB]
Quercus Muehlenbergii Engelm. [G, P & S, Steyererm., Deam]

This is the commonly encountered form of var. *acuminata* throughout Missouri.

Ranges from Florida to Texas, north to Vermont, New York, Ontario, Michigan, Wisconsin, Minnesota, and Nebraska. Also in New Mexico and Mexico.

7c. ***Quercus prinoides* var. *acuminata* f.**

Alexanderi (Britt.) Steyererm. Map 765a

Quercus acuminata var. *Alexanderi* (Britton) Farwell,
Mich. Acad. Sci. Rpt. 6: 206. 1904.

765a • *Quercus prinoides* var. *acuminata* f. *acuminata* (Chestnut Oak)
765a □ *Quercus prinoides* var. *acuminata* f. *Alexanderi*

766 • *Quercus imbricaria* (Shingle Oak)
766 □ *Quercus X anceps* (*Quercus falcata* X *imbricaria*)
766 † *Quercus X tridentata* (*Quercus imbricaria* X *marilandica*)
766 x *Quercus X Egglestonii* (*Quercus imbricaria* X *shumardii* var. *schneckii*)

767 • *Quercus Phellos* f. *Phellos* (Willow Oak)
767 □ *Quercus X filialis* (*Quercus Phellos* X *velutina*)
767 † *Quercus X ludoviciana* (*Quercus falcata* X *Phellos*)
767 x *Quercus X moultonensis* (*Quercus Phellos* X *shumardii*)

Generally occupying low ground in bottom woods, river flood plain, or low slopes along streams. Scattered throughout the range of var. *acuminata* in Missouri.

In many parts of western Missouri especially where *Q. prinoides* var. *prinoides* occurs, dwarf plants of *Q. prinoides* var. *acuminata* are difficult to distinguish as such from var. *prinoides*. The leaves of var. *acuminata* are generally larger, 10–20 cm. long, with the margins of the leaf-blades with usually 8–13 teeth, but there may be only 7 and these vary from blunt or rounded and low to prominent and more sharply pointed, and when such specimens have smaller leaf-blades, there are no other characters to separate them from *Q. prinoides* var. *prinoides*. Frequently, fruiting specimens only 2–3 feet tall of var. *acuminata* occur (*Steyermark 72315* from Carter Co.; *Steyermark 69988b* from Nodaway Co.; *Steyermark 70200* from Sullivan Co.; *Steyermark 70101* from Buchanan Co.; *Steyermark 72821* from Clinton Co.; and many others) with the slender twigs of var. *prinoides* and with little or no difference in size of acorns or cups as compared with those of var. *prinoides*. While *Q. prinoides* var. *prinoides* may frequently have somewhat smaller acorns and acorn cups with somewhat more tuberculate scales than those of var. *acuminata*, such differences certainly do not hold and are found to be extremely inconstant. Such frequent series of intergradations seen in the field and collected for deposit in the herbarium have made it seem hopeless to recognize the two oaks as more than extreme varieties of one variable species.

If they may be called incipient species, they have not diverged sufficiently to merit ordinary specific recognition.

In autumn the foliage of *Q. prinoides* var. *acuminata* turns an orange or brilliant red color. The kernel of the acorns of this variety are quite sweet and good to eat. The hard durable wood is used for railroad ties, fences, wheels, barrels, and fuel.

Hybrids are known between this variety and other oaks. In Missouri only *Quercus* × *Deamii* Trel. (*Q. macrocarpa* × *prinoides* var. *acuminata* [*Muehlenbergii*]) is the hybrid found involving var. *acuminata*. It was discussed under *Q. macrocarpa*.

8. *Quercus imbricaria* Michx. Shingle Oak

Also called Laurel Oak.

Map 766

Flowers early April–May.

Occurs in a variety of habitats, varying from upland and dry woods, borders of prairies, slopes, ravine bottoms, valleys, and bottom woods along streams. Common in all parts of Missouri with the exception of some of the extreme southern and southwestern counties, where apparently absent.

Ranges from New Jersey, Pennsylvania, to Wisconsin, Iowa and Nebraska, south to South Carolina, Tennessee, Mississippi, Arkansas, and Kansas. Reported as introduced in Massachusetts and New York.

This oak holds its green color when most of the other oaks have turned other colors. Eventually the foliage in late autumn turns orange or russet brown,

PLATE NO. 136

and sometimes red with green or brown. The leaves, which are somewhat like those of species of Mountain Laurel (*Rhododendron maximum* and *catawbiense*) in size and shape, although thinner, persist for some time into the winter. The tree can be used in ornamental plantings for hedges, screens, and windbreaks.

The wood of this species is considered relatively inferior as oak goes, and is only occasionally used in construction. However, the early settlers of Illinois used this oak especially for shingles, and in this capacity the wood is still used in Tennessee and some other states. The species is often subject to leaf spot and other fungus diseases which sometimes discolor leaves or defoliate trees.

Quercus imbricaria is known to hybridize with no less than six other species, all in the black oak group of which the following six are involved in Missouri:

Quercus × anceps Palmer (*Q. falcata* × *imbricaria*), known only from Butler County (upland woods, Poplar Bluff, October 5, 1921, *Palmer 20674*).

Quercus × Egglestonii Trel. (*Q. imbricaria* × *Shumardii*); *Quercus* × *Shirlingii* Bush ex Palmer & Steyermark. [P & S, Steyermark.], known only from Jackson County (Oak Grove, October 22, 1927, *Bush 11637*, holotype).

Quercus × exacta Trel. (*Q. imbricaria* × *palustris*), known from De Kalb, Sullivan, Shelby, Boone, and Jefferson counties.

Quercus × leana Nutt. (*Q. imbricaria* × *velutina*), known in a number of widely scattered counties throughout Missouri. In Kansas City, Jackson County, a tree of this hybrid has been measured as 9 feet, 3 inches in circumference at 4½ feet above the ground, with a height of 68 feet and a spread of 62 feet. It is at present recorded as the largest tree of this hybrid known.

Quercus × runcinata (A. DC.) Engelm. (*Q. imbricaria* × *rubra* [*borealis* var. *maxima*]), known from St. Louis (Allenton, *Letterman 2*, 5, 6, 36), Carter (Van Buren, *Palmer 19497*), and Jackson (near Independence, *Bush 623, 628, 10347-A*; Kansas City, *Laughlin*) counties.

Quercus × tridentata (A. DC.) Engelm. (*Q. imbricaria* × *marilandica*) St. Louis Oak

Known definitely in Missouri only from Cape Girardeau County (Cape Girardeau, June 22, 1920, *Palmer 18012*). A record attributed supposedly to St. Louis County (6 mi. east of St. Louis, autumn, 1849, *George Engelmann*) should be judged instead as occurring in the vicinity of East St. Louis, Illinois.

9. *Quercus Phellos* L. f. *Phellos*

Willow Oak

Map 767

Quercus Phellos L. [G, BB, P & S]

Flowers early April–May.

Occurs in wet or low woods bordering swamps, slow streams, bayous, and drainage canals in the lowlands of southeastern Missouri north to Scott, Bollinger, and Madison counties, west to Wayne and Ripley counties; locally north in St. Louis County where reported by Murtfeldt, but no extant tree is known in that county.

Ranges from Florida to Texas, north on coastal plain to New York, New Jersey, Pennsylvania, and inland to Illinois, Missouri, and Oklahoma.

A form of *Q. Phellos*, in which the lower surface of the leaves is permanently silky hairy with whitish hairs, known as *f. intonsa* Fern., is not recorded from Missouri.

The foliage, among the last of the oaks to turn color, eventually becomes pale yellow or dull gold in autumn. It makes a good shade tree and adorns the streets of many southern towns, along with evergreen live oak (*Q. virginiana*) and with laurel oak (*Q. laurifolia*). The wood of this species at one time served for rims or felloes of wheels and was also employed for railroad car timber. Today, sold on the market as red oak, it supplies the market for barrels, interior finish, stairs, posts, railings and supports for railings, church seats and pulpits, and for other kinds of items where the surface is subjected to wear and use.

Eight hybrids are recorded, involving *Quercus Phellos* as one of the parents. The following four are known from Missouri:

Quercus × filialis Little (*Q. Phellos* × *velutina*)

Quercus × *inaequalis* Palmer & Steyermark. [P & S, Steyermark.]

Known only from Butler County (Poplar Bluff, September 11, 1919, *Palmer 16342*, holotype of *Q. × inaequalis*).

Quercus × heterophylla Michx. f. (*Q. Phellos* × *rubra* [*borealis* var. *maxima*]) Bartram Oak

Known only from Wayne (northwest of Wappapello, September 2, 1938, *Steyermark 6428*) and Dunklin (Crowley Ridge, August 7, 1932, *Kellogg 26039*) counties.

Quercus × ludoviciana Sarg. (*Q. falcata* × *Phellos*) *Quercus subfalcata* Trel.

Known from southeastern Missouri from Carter, Butler, and Dunklin (Campbell, July 28, 1895, *Bush 610-B*) counties.

Quercus × moultonensis (*Q. Phellos* × *Shumardii* var. *Shumardii*).

Known only from Ripley County (along Current River in low woods near Current View, August 7, 1934, *Steyermark 14334*).

768 *Quercus nigra* var. *nigra* f. *nigra* (Water Oak)769 • *Quercus marilandica* (Black Jack Oak)
769 □ *Quercus* X *Bushii* (*Quercus marilandica* X *velutina*)770 • *Quercus falcata* var. *falcata* f. *falcata* (Spanish Oak)
770 □ *Quercus falcata* var. *falcata* f. *angustior*
770 X *Quercus falcata* var. *falcata* f. *triloba*
770 X *Quercus falcata* var. *pagodaefolia* (Cherry Bark Oak)10. *Quercus nigra* L. var. *nigra* f. *nigra*

Water Oak

Map 768

Flowers early April–May.

Occurs in low wet woodland bordering swamps, bayous, or slow streams of the lowland section of southeastern Missouri, where it is found in Pemiscot, Dunklin, Butler, and Ripley counties.

Ranges from Florida to Texas, north on the coastal plain to Delaware, and inland north to Kentucky, Missouri, and Oklahoma.

The leaves vary considerably in shape and size. A form of *Q. nigra* var. *nigra* in which the upper part of the leaf is deeply cleft into 3 narrow oblong lobes is known as f. *tridentifera* (Sarg.) Trel., but has not been recorded from Missouri, nor has the var. *heterophylla* (Ait.) Ashe, in which some or all of the leaves are deeply cut almost to the midrib with 2 narrow long lobes below the ones of the broad summit.

In the southeastern states the tree is often seen as a shade tree. It is occasionally used in southeastern Missouri as such. The wood does not seem to be much used except for fuel. Seven hybrids involving *Q. nigra* as one of the parent species are recorded, but none has been recorded from Missouri.

11. *Quercus marilandica* Muenchh.

Black Jack Oak

Map 769

Flowers early April–May.

Occurs in acid soils on dry or rocky upland, often level woods or slopes, sometimes on rocky glades of sandstone, chert, or granite. Commonly found in southern and central Missouri, especially throughout the Ozark and unglaciated prairie sections, ranging northward on poor and acid soils to the Iowa border, extending west in northern Missouri to Putnam, Sullivan, Livingston, and Clinton counties, and locally northwest in Gentry County.

Ranges from Florida to Texas, north to New York,

Pennsylvania, Ohio, Michigan, Indiana, Illinois, Iowa, and Nebraska.

The leaves are rather thicker and more rigid than in most of the other native Missouri species. In autumn they turn brilliant combinations varying from crimson and mixed orange, red, and brown, to crimson or carmine with russet-brown. The leaves are rather variable in shape, but in general have a broadly dilated fan-shape with usually three main broad shallow lobes around the summit. A specimen from Putnam County (Palmer 27929) is a peculiarly lobed, small-leaved form with additional lateral lobes below the usual dilated fan-shaped upper portion, and may be considered as an exceptional leaf variant of the species.

The wood is largely used for fuel and in the manufacture of charcoal. Many sections of the eastern Ozarks at one time supplied the iron smelters of that region with charcoal derived from this species. Such settlements as Sligo and St. James had smelter furnaces until about 1915.

Of the eight hybrids recorded involving *Quercus marilandica* as one of the parent species, the following two are known to occur in Missouri:

Quercus* × *Bushii Sarg. (*Q. marilandica* × *velutina*)

This hybrid is known from nearly a dozen counties scattered through southern, central, and eastern Missouri northeast to Lewis County. The largest tree recorded for this hybrid exists in Forest Park, St. Louis County. It has a circumference of 8 feet, 7 inches at 4½ feet above the ground, is 67 feet tall, and has a spread of 49 feet.

Quercus* × *tridentata (A. DC.) Engelm. (*Q. imbricaria* × *marilandica*)

This has been previously referred to under *Q. imbricaria*.

12. **Quercus falcata** Michx. Spanish Oak

Map 770

Also known as Southern Red Oak, Cherry Bark Oak

Flowers early April–May.

Very variable in the shape of the leaves and their lobing. The following variations are found in Missouri:

- a. Leaves uncut except toward summit into 3 short blunt or rather blunt lobes, the middle lobe about equal to the other lobes in length.

12c. *Q. falcata* var. *falcata* f. *triloba*

- a. Leaves cut into 3–5 long narrow lobes or into 5–11 short and broad or long and narrow lobes, the terminal lobe usually longer than the other lobes b

- b. The 5–11 lobes of the leaf more or less regular and equal-sided, scarcely curved on one side or sickle-shaped, with some of the lateral (side) lobes usually cut less than halfway to the midrib and spreading at nearly right angles to main length of leaf-blade . . . 12d. *Q. falcata* var. *pagodaefolia*

- b. The 3–5 (rarely 7) lobes of the leaf unequal, the terminal lobe or 2 of the side lobes greatly prolonged and often unequal-sided, curved, or sickle-shaped, and usually cut more than halfway to the midrib . . . c

- c. Leaves ovate or obovate, the lateral lobes 4–8 cm. long, 1.5–2 cm. broad, 2–3 times as long as broad . . . 12a. *Q. falcata*

var. *falcata* f. *falcata*

- c. Leaves oblanceolate or oblong, the shorter lateral lobes 1–3.5 cm. long, 1.5–2 cm. broad, about as long as broad or only 1½ times as long as broad . . .

12b. *Q. falcata* var. *falcata* f. *angustior*

12a. **Quercus falcata** Michx. var. **falcata** f. **falcata**

Spanish Oak, Southern Red Oak

Map 770

Quercus falcata Michx. [G, P & S, Steyer., Deam]

Occurs in acid soils of chert or sandstone on rocky or clayey upland ridges and hills, or in valley or river bottom woods. Southern Missouri, throughout the lowlands of southeastern Missouri north to Perry County and west along the southern border counties to Barry County. This is the commonest variation in Missouri.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Missouri, and Oklahoma.

12b. **Quercus falcata** var. **falcata** f. **angustior**

Palmer & Steyer.

Map 770

Quercus falcata f. *angustior* Palmer & Steyer.

[Steyer.]

Known only from Oregon County (along Eleven Points River, ½ mi. north of McCormack Hollow, 3 mi. north of Greer, July 27, 1936, Steyermark 12318, holotype in Mo. Bot. Gard. Herbarium).

12c. **Quercus falcata** var. **falcata** f. **triloba**

(Michx.) Palmer & Steyer.

Map 770

Quercus falcata f. *triloba* (Michx.) Palmer & Steyer.

[P & S, Steyer., Deam]

Quercus falcata var. *triloba* (Michx.) Nutt. [G]

Found in southeastern Missouri north to Cape Girardeau County and west to Oregon County.

12d. **Quercus falcata** var. **pagodaefolia** Ell.

Cherry Bark Oak

Map 770

Quercus falcata var. *leucophylla* (Ashe) Palmer & Steyer. [P & S, Steyer., Deam]

Occurs in low bottom or valley woods in the southeastern lowland section, north to Cape Girardeau County and west to Butler County.

Ranges from Florida to Louisiana, north to New Jersey, Kentucky, Indiana, Illinois, and southeastern Missouri.

This variety receives the name Cherry Bark, because the scaly reddish-tinged bark resembles somewhat that of a black cherry.

It does not appear possible to maintain var. *leucophylla* as a separate variety, the character of whitish versus brownish pubescence, and diversity in types of leaves on upper and lower branches not appearing to be consistent or reliable differences.

Much more field work and experimental studies are needed before a final judgment can be drawn on the relative values of variation in leaf lobing and shape of the many variations found in *Q. falcata*.

The foliage of *Q. falcata* turns a dull orange and brown color in autumn. The tree is sometimes seen as a shade specimen in some of the towns of southeastern Missouri. The wood is used as pulp for paper making and fuel, and the bark is used for tanning leather. The wood of var. *pagodaefolia* is often used for telegraph poles, furniture, crates, and boxes, and is considered superior to that of var. *falcata*.

Eight hybrids have been recorded involving *Q. falcata* as one of the parent species. In Missouri two of these are known, *Quercus* × *ludoviciana* Sarg. (*Q. falcata* × *Phellos*), already referred to previously under *Q. Phellos*, and *Quercus* × *anceps* Palmer (*Q. falcata* × *imbricaria*), already referred to under *Q. imbricaria*.

13. **Quercus velutina** Lam. Black Oak Map 771

Also called Yellow-barked Oak

Flowers early April–May.

Occurs often in acid thin soils on rocky or dry sandy or upland slopes and ridges, rocky glades of sandstone, chert, or granite, in rich or well-drained ground along streams, and borders of woods and fields. Found throughout Missouri, and doubtless in every county.

Ranges from Florida to Texas, north to Maine, New York, Ontario, Michigan, Illinois, Minnesota, and Nebraska.

The leaves of this species vary considerably in lobing and pubescence. Missouri material is divided into the following variations:

- a. Fully grown twigs, leaf-stalks (petioles), and lower surface of fully grown leaves more or less covered with hairs . . . 13b. *Q. VELUTINA* f. *MISSOURIENSIS*
- a. Fully grown twigs mostly glabrous (without hairs), the young ones hairy; fully grown leaf-stalks and lower surface of leaves mostly glabrous except for remains of hairs along some of main nerves and their axils . 13a. *Q. VELUTINA* f. *VELUTINA*

13a. *Quercus velutina* f. *velutina* Map 771

Quercus velutina Lam. [G, BB, P & S, Steyermark.]

Quercus velutina f. *macrophylla* (Dippel) Trel. [G]

Quercus velutina f. *dilaniata* Trel. [G]

Quercus velutina f. *pagodaeformis* Trel. [G]

Quercus leiodermis Ashe [P & S]

This form, including the various leaf variations, is the more commonly encountered one in Missouri. The various forms included above in the synonymy of *f. velutina* are not recognized principally because differences in leaf lobing are often to be found on one and the same tree, from upper or lower branches, or represent various stages of maturity. Typical *Q. velutina* f. *velutina* is considered to be a rather rare form of *Q. velutina*, but is encountered frequently on young shoots, in which the leaves are obovate and sinuate or very shallow-lobed; *Q. velutina* f. *macrophylla* has the leaves cut less than halfway to the midrib with the toothed broadly oblong lobes many times broader than the narrow spaces (sinuses); *Q. velutina* f. *dilaniata* has the leaves cut from 1/2–3/4 distance to the midrib, the oblong lobes are often narrower than the broad spaces (sinuses) and much toothed at their summit; *Q. velutina* f. *pagodaeformis* has deeply lobed leaves and the long-pointed lobes are scarcely or not at all toothed. All these forms occur in Missouri, the commonest one being *f. dilaniata*, with *f. macrophylla* also frequent. Leaves from juvenile or immature shoots have leaf-shapes and lobing found in both typical *f. velutina* and *f. macrophylla*.

13b. *Quercus velutina* f. *missouriensis* (Sarg).

Trel. Map 771

Quercus velutina var. *missouriensis* Sarg. [P & S, Steyermark.]

Scattered throughout the state.

In autumn Black Oak usually changes to a bright yellow color, but also may be dull orange to red brown. The inner bark, which is yellow, yields a yellow dye known as *quercitron* and contains the substance *quercitrin*. The yellow extract is used in cotton and wool printing producing a yellow color said to be comparable to that obtained from fustic (the dye extracted from the tropical American tree, *Chlorophora tinctoria*). One of the glucosides found in *quercitrin* is being studied because of its vitamin possibilities. The bark contains much tannic acid, and, like some other species of oaks, is used in tanning.

The wood, which is judged inferior to red oak, is sold nevertheless as red oak and is used in similar ways. Besides its use as fuel, it is employed for railroad cars, flooring, barrels, and rough lumber.

Ten hybrids have already been described which involve *Quercus velutina* as one of the parent species, and in Missouri the following five are known to occur:

Quercus × *Bushii* Sarg. (*Q. marilandica* × *velutina*), already referred to previously under *Q. marilandica*.

Quercus × *filialis* Little (*Q. Phellos* × *velutina*), referred to previously under *Q. Phellos*.

Quercus × *Hawkinsiae* Sudw. (*Q. rubra* [*borealis* var. *maxima*] × *velutina*)

Quercus × *Porteri* Trel.

Known from Clark (Dumas, Palmer 21904, Bush 9528), Dunklin (Crowley Ridge, Kellogg 26043), and Jackson (Holmes Park, Kansas City, Bush 9944; Swope Park, Kansas City, Laughlin) counties.

Quercus × *leana* Nutt. (*Q. imbricaria* × *velutina*), previously accounted for under *Q. imbricaria*.

Quercus × *vaga* Palmer & Steyermark. (*Q. palustris* × *velutina*).

Known only from Nodaway County (Maryville, June 13, 1924, Palmer 25421, holotype in Arnold Arboretum Herbarium).

14. *Quercus ellipsoidalis* E. J. Hill

Jack Oak Map 772

Also called Northern Pin Oak, Hill's Oak

Flowers May–June.

Known only from dry upland bordering woods in acid soil near the Iowa border in northern Missouri in Harrison County (near Eagleville, July 6, 1933, Palmer & Steyermark 41358).

771 • *Quercus velutina* f. *velutina* (Black Oak)771 † *Quercus velutina* f. *macrophylla*771 □ *Quercus velutina* f. *dilaniata*771 x *Quercus velutina* f. *missouriensis*771 † *Quercus* X *Leana* (*Quercus imbricaria* X *velutina*)772 *Quercus ellipsoidalis* (Jack Oak)773 • *Quercus coccinea* var. *coccinea* (Scarlet Oak)773 □ *Quercus coccinea* var. *tuberculata*

Ranges from southern Michigan to southern Manitoba, south to northern Ohio, northern Indiana, northern Illinois, Iowa, northern Missouri, and south-eastern North Dakota.

The species has been divided into two forms based on the shape and size of the acorn:

Acorn distinctly longer than thick, ellipsoid-cylindric, narrowed at both ends, 15–20 mm. long

Q. ELLIPSOIDALIS f. *ELLIPSOIDALIS*

Acorn somewhat longer than thick, oblong-ovoid to subglobose, rounded at base and at summit, 12–16 mm. long. . . . *Q. ELLIPSOIDALIS* f. *DEPRESSA*

Since both types and all gradations of acorns may be found on the same tree, as observed repeatedly on trees in northern Illinois, no importance should be given to this range of normal variation. The leaves vary from deeply lobed with the cutting more than halfway to the midrib to less than halfway, and with the base of the leaves wedge-shaped to truncate. The opportunity to live in an area in northern Illinois during the past twenty years where this species is the dominant tree around the author's residence has afforded him unlimited and frequent observations of winter buds. Although winter buds are sometimes reported as only 1–3 mm. long (Wadmond, S. C., Trans. Acad. Sci. 28: 203, 1933), they are, when fully grown, 4–7 mm. long. Rather than having the upper scales 'inconspicuously ciliate-pubescent or nearly glabrous' under which division of the key this species would fall in Palmer's key to the species and varieties of red oaks (Am. Midl. Nat. 27: 739, 1942), the winter bud-scales in *Q. ellipsoidalis* are covered with a gray silky or appressed type of fine pubescence which is general over most of the surface. The cups and acorns vary in size.

In having a yellow inner bark *Quercus ellipsoidalis* may be more easily mistaken for *Q. velutina* than any

other species. The best criterion for separating the two lies in the loose overlapping or fringe development of the upper scales of the acorn cup in *Q. velutina* as contrasted with the tightly appressed ones of *Q. ellipsoidalis*, and in the longer more angled, more densely pubescent terminal winter buds of *Q. velutina*, which are 6–12 mm. long, as contrasted with 4–7 mm. long in *Q. ellipsoidalis*. Also, it can be stated that the leaves of *Q. velutina* are much thicker and more shining on the upper surface than those of *Q. ellipsoidalis*, but this can be judged only when one is sufficiently well acquainted with the two species, so this leaf contrast at best is only relative. The leaves of *Q. ellipsoidalis*, in fact, are about as thin as in *Q. shumardii* and nearly as thin as in *Q. coccinea*.

The foliage of *Q. ellipsoidalis* takes on brilliant colors in autumn, sometimes scarlet or crimson-red hues. In early spring the young leaves are deep purple-red or blood red, and the older ones become green and yellow with some rose. The lower branches of the tree have a habit of dying, with the spreading to drooping dead limbs remaining indefinitely attached and giving the tree an untidy appearance. The species also appears to be one of the weaker oaks and is subject to windfall and storms which are known to topple over large trees of this species. Trees which have been blown down during wind storms usually reveal a root system which appears to be rather weak and superficial, and a trunk with a heart wood which had begun to rot near the base after the tree had reached a certain age.

An effort should be made throughout the counties in northern Missouri to locate more stands of this interesting species. No timber value is known for *Q. ellipsoidalis*. Bronze grackles, and gray and fox squirrels are fond of the acorns of this and other species of *Quercus*.

A hybrid is recorded between this species and *Q. velutina* (as *Q. × palaeolithicola* Trel.) but has not been found in Missouri.

15. ***Quercus coccinea* Muenchh.** Scarlet Oak

Map 773

Flowers April–May.

Occurs in acid soils associated with sandstone, chert, flint, or granite rocks, either on narrow ridges, ravine slopes, or in upland woods bordering headwaters of tributary streams. Restricted to the eastern half of the Ozark region ranging there north to Ste. Genevieve, Washington, and Crawford counties, west to Dent, Texas, Howell, and eastern Douglas County, where it reaches its southwesternmost station in the sandstone hills following the drainage of Indian Creek, northeast and south of Topaz.

Ranges from Maine, New York, Ontario, Ohio, southern Indiana, southern Illinois, and southern Missouri, south to Georgia, Alabama, northern Mississippi, and northeastern Arkansas.

The species is sometimes divided into two varieties on the basis of fruiting characters. Much more field work and experimental studies need to be carried out in connection with the variation of the fruits of this species. Until more exhaustive work has been done, the var. *tuberculata*, which has not been recognized either in *Gray's Manual*, eighth edition, or in Gleason's *New Britton and Brown*, is being maintained in the present work.

Acorns mainly 20–25 mm. long; scales of cup not thickened with any tubercle (wartlike enlargement); cup 20–23 mm. wide; common type

15a. *Q. COCCINEA* var. *COCCINEA*

Acorns mainly 25–30 mm. long; lower scales of cup with a conspicuous thickened tubercle (wartlike enlargement); cup often 25–30 mm. wide; rare, known only from Butler County

15b. *Q. COCCINEA*
var. *TUBERCLATA*

15a. ***Quercus coccinea* var. *coccinea*** Map 773

Quercus coccinea Muenchh. [G, BB, P & S, Steyerl.]

Quercus × Richteri Baenitz [P & S, Steyerl.]

This is the usual fruiting variation encountered.

15b. ***Quercus coccinea* var. *tuberculata* Sarg.**

Map 773

Known only from Butler County in southeastern Missouri (gravelly hills near Poplar Bluff, October 5, 1921, *Palmer 20678*; same locality, November 14, 1935, *Palmer 29638*).

Ranges from Massachusetts to Indiana and Missouri, south to Alabama and Tennessee.

Among the most brilliantly red trees in autumn this species of oak ranks near the top in Missouri, along with Sour Gum and Red Maple as rivals. In early autumn Scarlet Oak is still mostly green, but in late autumn about the first part of November or the very last of October, it attains its most brilliant aspects of deep red. It is sometimes planted for its handsome foliage, but transplants with great difficulty.

The bark of mature trees of Scarlet Oak resembles that of Northern Red Oak (*Q. rubra*) in having a smooth pale gray or gray-brown surface interrupted by darker shallow vertical furrows. The bark is usually given a pale mottled gray and greenish-white appearance by the pale lichens which attach over much of the surface. The inner bark is reddish. The conspicuous acorn cup with nearly glabrous, closely set, tightly appressed, glossy scales, and glabrous lower portion of the buds are reliable characters that serve to separate Scarlet Oak from other species with which it might be mistaken. The winter buds are more pubescent than in either Northern Red Oak (*Q. rubra*) or Shumard Oak (*Q. shumardii*), but less pubescent than in Black Oak (*Q. velutina*), the pubescence on the buds of *Q. coccinea* limited to the upper section and only sparsely so. The leaves of Scarlet Oak are quite thin and have a texture similar to thin parchment paper, and are green on both sides. They are not shiny as in either Black Oak (*Q. velutina*) or Shumard Oak (*Q. shumardii*). They are thinner than those of either Black Oak or Shumard Oak, more deeply cut than either those of Black Oak or Northern Red Oak (*Q. rubra*) and as deeply cut as in Pin Oak (*Q. palustris*), Jack Oak (*Q. ellipsoidalis*), and Shumard Oak (*Q. shumardii*). The axillary tufts of hairs on the lower leaf surface, which are so conspicuous in the Black Oak and Shumard Oak, are either not present or else not conspicuous in Scarlet Oak.

On the narrow ridge tops and heads of tributary ravines in the Ozarks it is usually associated with other species of oak, sour gum, pine, flowering dogwood, and red maple.

The wood of this species is used principally for wagons, barrels, chairs, boats, and agricultural implements, and is usually marketed as black oak.

No hybrids are known in Missouri involving this species. Palmer (Jour. Arn. Arb. 29: 38. 1948) concurs with Croizat (Torreya 36: 139–42. 1936) that *Q. × Richteri* is synonymous with *Q. coccinea* and not a hybrid between *Q. rubra* [*borealis* var. *maxima*] and *palustris* as formerly maintained. Specimens from Osage and Benton counties, cited from Missouri previously as *Q. × Richteri*, are still to be considered as hybrids between *Q. rubra* and *palustris*, but no formal

name has been assigned to this hybrid up to the present time.

16. *Quercus Shumardii* Buckl.

Map 774

Flowers early April–May.

The species is represented by two variations, based principally on the shape of the acorn cup:

Cup of acorn flattish, shallow, saucer-shaped, 20–30 mm. broad, enclosing about $\frac{1}{4}$ of the acorn; trees usually of low or alluvial woods, but also in upland woods . . . 16a. *Q. SHUMARDII*

var. *SHUMARDII*

Cup of acorn deeper, strongly rounded or convex below, bowl-shaped, 20 mm. or less broad, enclosing $\frac{1}{3}$ – $\frac{2}{5}$ of the acorn; trees of drier, upland or rocky woods, glades, or edges of bluffs . . .

16b. *Q. SHUMARDII* var. *SCHNECKII*

16a. *Quercus Shumardii* var. *Shumardii*

Shumard Oak

Map 774

Also called Water Oak, Spotted Oak, and Red Oak

Quercus Shumardii Buckl. [G, P & S, Steyerml.]

Occurs frequently in the valleys and along banks of the larger Ozark streams usually in low and alluvial ground, but also found in upland drier situations. Southern and central Missouri north to Ralls, Saline, and Jackson counties.

Ranges from Florida to Texas, north to Maryland, Pennsylvania, West Virginia, Ohio, Indiana, Illinois, Missouri, Kansas, and Oklahoma.

16b. *Quercus Shumardii* var. *Schneckii* (Britt.)

Sarg. Schneck Oak

Map 774

Usually frequents drier and rockier situations on the upland, on glades and edges of bluffs, and in rocky woods. Southern and central Missouri, where common throughout the Ozark and unglaciated prairie sections, north to Pike, Monroe, Boone, Saline, and Clay counties; absent from most of the lowland section of southeastern Missouri.

Ranges from Ohio, Indiana, Missouri, and Kansas, south to Tennessee, Arkansas, and Oklahoma.

This variety is not recognized by the United States Forest Service, it being combined with *Q. Shumardii* var. *Shumardii*. While it is true that intermediates and intergrading forms occur and cannot be identified positively as one or the other variety, it can also be maintained that frequent field contact with these

varieties serves to emphasize more their differences. Until additional new evidence is at hand to indicate that var. *Shumardii* and var. *Schneckii* are not distinct varieties, the present treatment maintains them along with the judgment of Deam, Palmer, Fernald, Gleason, and the author's own field knowledge of them. Palmer (Am. Midl. Nat. 27: 739. 1942) also emphasizes differences between var. *Shumardii* and var. *Schneckii* in leaf variation: in var. *Schneckii* the leaves are essentially uniform on upper and lower branches, whereas in var. *Shumardii* those on the upper branches of old trees are more often deeply divided than the ones on the lower branches. Since these differences are frequently not observed in the field nor are to be judged on herbarium material, it is usually impossible to rely on these vegetative criteria, and it can only be recommended here that such observations be encouraged for future appraisal of the distinctness of the varieties.

These two varieties are easily distinguished from Northern Red Oak (*Q. rubra*) by the gray, glabrous, acute buds and more deeply cut leaves which are shiny on the upper surface. The bark of the *Q. Shumardii* varieties is dark with broken furrows, while that of Northern Red Oak is paler gray and the furrows more continuous. The completely glabrous gray buds distinguish the *Q. Shumardii* group from Jack Oak (*Q. ellipsoidalis*), Scarlet Oak (*Q. coccinea*), and Black Oak (*Q. velutina*). The bark is not rough as in *Q. velutina* or *Q. ellipsoidalis*, and the inner bark is reddish to gray, not yellow. For leaf distinctions between *Q. Shumardii* and *Q. Nuttallii*, refer to remarks under the latter species.

The wood of the *Q. Shumardii* group is usually classified by lumber merchants as red oak and accordingly given uses similar to red oak (*Q. rubra*). The trees have been found to do well when planted along streets and highways.

Six hybrids have been recorded which involve either one or the other of these varieties as parents, and in Missouri the following three have been found:

***Quercus* × *Egglestonii* Trel.** (*Q. imbricaria* × *Shumardii* var. *Schneckii*), already referred to previously under *Q. imbricaria*,

Quercus* × *moultonensis (*Q. Phellos* × *Shumardii* var. *Shumardii*), already referred to previously under *Q. Phellos*, and

776 o *Quercus rubra* var. *rubra x palustris*

***Quercus x mutabilis* Palmer & Steyererm.** (*Q. palustris x shumardii* var. *schneckii*).

Known from Mississippi, Wayne (Palmer 19423), Butler (Bush 3770), Benton (Palmer 26358), and Bates (Monteith Junction, September 10, 1924, Palmer 26069, holotype) counties.

17. *Quercus palustris* Muenchh. Pin Oak

Map 775

Also called Turkey Oak, Swamp Oak, and Water Oak in some portions of Missouri.

Flowers early April–May.

Occurs in alluvial ground in valleys and low ground of flood plain forests, bordering streams, oxbow lake meanders, sloughs, and river bottom meadows, sometimes on dry upland as relicts around old sink-hole ponds in the Ozarks. Throughout Missouri, but absent from most sectors of the main Ozark region.

Ranges from South Carolina to Louisiana and Oklahoma, north to Massachusetts, Pennsylvania, Ontario, Michigan, Illinois, Iowa, and Kansas.

For distinctions between the leaves of this species and *Q. Nuttallii*, refer to the remarks under that species.

The foliage of this species in autumn is quite colorful, turning from green tinged with carmine, or reddish-green, to scarlet. Especially in open or sunlit places, the tree develops a pyramidal shape with more or less horizontal, long, slender middle branches and drooping lower branches, giving it a distinctive and graceful appearance. Because of this, it is frequently planted as an ornamental tree. The campus at Washington University in St. Louis has beautiful specimens of this species, and many parks and streets

in Missouri and elsewhere show off the landscaping qualities of the Pin Oak to good advantage. In nature the lowest drooping branches of the Pin Oak are usually much crowded and shaded by branches of other trees in a lowland forest, and eventually die. They remain attached to the tree for some time, but the pinlike or spurlike stumps of the branches which have broken away remain and give the name Pin Oak. Where the tree is allowed to develop in a situation where it is not crowded nor shaded, these lower branches continue to grow and add to the beauty of the tree.

The wood is considered inferior to that of Red Oak (*Q. rubra*) because it is usually full of knots produced from the numerous branches of the tree, but is used in construction, rough siding as clapboard for buildings, and for shingles.

Of the four hybrids involving this species, three of them are known from Missouri:

***Quercus x exacta* Trel.** (*Q. imbricaria x palustris*), previously referred to under *Q. imbricaria*.

***Quercus x mutabilis* Palmer & Steyererm.** (*Q. palustris x shumardii* var. *schneckii*), previously referred to under *Q. shumardii*.

***Quercus x vaga* Palmer & Steyererm.** (*Q. palustris x velutina*), previously referred to under *Q. velutina*.

18. *Quercus rubra* L. Red Oak

Map 776

Also called Northern Red Oak

Flowers April–May.

Two variations, based chiefly on the fruit, occur in Missouri:

Common type found throughout Missouri; cup of acorn shallow, saucer-shaped, flat on the

bottom, covering about 1/4 of cup, 18–30 mm. broad 18a. *Q. RUBRA* var. *RUBRA*
Rarely encountered, known only from Jackson and Macon counties; cup of acorn deeper, enclosing about 1/3 of acorn, bowl-shaped (hemispherical) or top-shaped (turbinate), 15–20 mm. (up to 25) broad 18b. *Q. RUBRA* var. *BOREALIS*

18a. ***Quercus rubra* var. *rubra*** Map 776
Quercus rubra L. [G]
Quercus borealis Michx. f. var. *maxima* [BB, P & S, Steyerl., Deam]

Occurs in well drained soils in rich ravines, north- and east-facing wooded bluffs, near heads of tributary streams and along streams, both in upland and lowland, on slopes or at the base of bluffs, in limestone, sandstone, chert, or granitic soil areas. Throughout Missouri, where known from essentially every county except the three most southeastern ones. It does not occur in soil which is subject to periodic inundation and flooding by streams, such as endured by Pin Oak.

Ranges from Nova Scotia, Quebec, Ontario, Michigan, Wisconsin, Minnesota, and Nebraska, south to Georgia, Alabama, Mississippi, Louisiana, Arkansas, and Oklahoma.

18b. ***Quercus rubra* var. *borealis*** (Michx. f.) Farw. Map 776
Quercus borealis Michx. f. var. *borealis* [BB]
Quercus borealis Michx. f. [P & S, Steyerl., Deam]

Known only from Macon and Jackson (woods along creek, Greenwood, September 10, 1921, *Palmer 20450*) counties in northern and west-central Missouri.

Ranges from Nova Scotia, Quebec, and Ontario, south to Maine, New York, Pennsylvania, North Carolina, Michigan, Wisconsin, Iowa, and Missouri.

The United States Forest Service unites the two varieties, but the two, although intergrading at the margins of their ranges, may be separated by the differences given in the key. The var. *borealis* is a more northern-ranging variety.

The foliage of this tree in autumn turns to orange or russet-brown with green. It makes a desirable ornamental tree, grows rapidly, and is recommended as one of the best of trees for planting along streets. Fortunately, unlike some other species of oaks, *Q. rubra* usually transplants easily. The inner bark, which is reddish, is responsible for the name of this and other related members of the group.

Commercially, red oak includes this species combined with other members of the clan, but the quality of the wood of the true red oak (*Q. rubra* and var. *borealis*) is considered superior for the most part to that of the other kinds, but not as good as white oak.

It is much used, however, in construction work for clapboards and rough lumber, barrels, railroad ties, as well as for furniture and interior finish of homes and offices.

Five hybrids have been recorded involving this oak and its variety as one of the parents. The following four are known to occur in Missouri:

Quercus* × *Hawkinsiae Sudw. (*Q. rubra* [*borealis* var. *maxima*] × *velutina*), previously referred to under *Q. velutina*.

Quercus* × *heterophylla Michx. f. (*Q. Phellos* × *rubra* [*borealis* var. *maxima*]), previously referred to under *Q. Phellos*.

Quercus* × *runcinata (A.DC.) Engelm. (*Q. imbricaria* × *Q. rubra* [*borealis* var. *maxima*]), previously referred to under *Q. imbricaria*.

Quercus rubra* [*borealis* var. *maxima*] × *palustris, referred to under discussion of *Q. × Richteri* Baenitz. Specimens representing the above cross are known from Osage and Benton counties.

19. ***Quercus Nuttallii*** Palmer Nuttall's Oak Map 777

Flowers April–May.

Occurs in low or wet woods, where known in the state only from New Madrid (Paw Paw Junction, September 3, 1897, *Bush 224*) and Butler (October 19, 1905, *Bush 3770*) counties in southeastern Missouri. Trees have been seen on the Joe Adamson place, T26N, R7E, sect. 27, 2 mi. north of Rombauer, along Mud Creek, where Mr. Adamson calls it 'Black Cherry-bark Oak,' a name usually applied to *Q. falcata* var. *pagodaefolia*. Here it has been observed by Mr. Albert Chandler, amateur botanist of Kirkwood, Missouri.

Ranges from Alabama to Texas, north to western Tennessee, southeastern Missouri, Arkansas, and southeastern Oklahoma.

Until described by Mr. E. J. Palmer in 1927 (*Jour. Arn. Arb.* 8: 52. 1927), this oak had not been distinguished. It is considered a commercially important species, known as red oak in the lumber industry, where it is employed in much the same manner as other red oak lumber.

This oak is sometimes confused with Pin Oak (*Q. palustris*) on account of the similar leaves and dead lower branches of the tree, but is easily distinguished in fruit by the deeper acorn cups which are narrowed into a stalklike base and the larger acorns and winter buds. The fruit of *Q. Nuttallii* also distinguishes it from *Q. Shumardii* var. *Shumardii* and var. *Schneekii*. By leaves alone, *Q. Nuttallii* may be dis-

tinguished, according to Dr. Dyal (Rh. 38: 60. 1936) from *Q. palustris* and *Q. Shumardii* var. *Shumardii* and var. *Schneckii* as follows: in *Q. Nuttallii* the lobes of the leaf are usually long-tapering and the main lobes have no small bristles at the sides less than 5 mm. from the very tip; in *Q. palustris* and *Q. Shumardii*, on the other

hand, the leaf lobes are rather blunt and some of the main lobes, at least, have 1-2 small bristles at the sides less than 5 mm. from the very tip.

A hybrid involving this species and *Q. Shumardii* var. *Shumardii* has been recorded, but up to the present time has not been found in Missouri.

HYBRID OAKS RECORDED FROM MISSOURI

For the geographical distribution of these in the state, refer to either of the parent species indicated in the cross.

Fam. **ULMACEAE** (Elm Family)

- a. Leaves with 4–6 main nerves on each side of midrib, the lowest pair arising from the base of blade, forming a 3-nerved or V-nerved part with the midrib; margins of leaves without teeth or with teeth only along part of the margin; branches with chambered pith; all the flowers appearing on the newest leafy branches; sepals separate, not united; fruit fleshy, a 1-seeded round drupe with thin pulp and tough skin, ripening in late summer or fall, but well-developed when the leaves are fully grown 3. **CELTIS**
- a. Leaves with usually 6–20 main nerves on each side of midrib, the lowest pair arising above the base of blade, all the nerves at nearly the same angle parallel to one another; margins of leaves toothed rather regularly from base to summit; branches with solid pith; some of the flowers appearing on branches of the previous year; sepals united forming a calyx tube with lobes; fruit dry, either a flat winged fruit (samara) or a wingless bur-like nut, ripening and falling before June *b*
- b. Flowers appearing before the leaves; fruit flat with a broad wing; margins of leaves with most of teeth usually double-toothed (each tooth cut into or broken); bark rough or ridged; trunk single 1. **ULMUS**
- b. Flowers appearing with the leaves; fruit a wingless bur-like nut; margins of leaves with most of teeth mostly simply-toothed (without any break or cut on each tooth); bark thin and scaly; trunk forking usually near base 2. **PLANERA**

1. **Ulmus** L. Elm

Species of this genus produce pollen which has been shown to be irritating and to cause some cases of hay fever.

- a. Upper surface of leaves rough, like sandpaper, to the touch, with erect stiff hairs; bud-scales conspicuously covered with dense orange-brown or rusty-colored hairs; inner bark slippery when chewed 4. **U. RUBRA**
- a. Upper surface of leaves more or less smooth to the touch, without hairs or these not stiff or erect; bud-scales either without hairs or the hairs either inconspicuous or not orange-brown or rusty-colored; inner bark not slippery when chewed *b*
- b. Cultivated tree or shrub, sometimes escaped from cultivation; leaves nearly equal-sided at the base; margins of leaves simply toothed (without any break or cut on each tooth); lower surface of leaves glabrous (without hairs); flowers nearly without stalks (sessile), not drooping; margins of fruits without hairs projecting 5. **U. PUMILA**
- b. Without the above combination of characters: native trees; leaves mostly unequal-sided at the base, one side longer or wider or more curved than other; margins of leaves usually double-toothed (each tooth slightly cut into or broken on one side); lower surface of leaves hairy or sometimes glabrous (without hairs); flowers with long stalks, soon drooping; margins of fruits with dense hairs projecting *c*
- c. None of the branches developing corky wings or woody outgrowths; flowers occurring in clusters or groups, their stalks originating from the same point; fruits glabrous on the side which covers the seed; lower surface of leaves hairy or becoming glabrous 1. **U. AMERICANA**
- c. Some of the young or old branches, or both, developing corky wings or woody outgrowths;

777 *Quercus Nuttallii* (Nuttall's Oak)

778 *Ulmus americana* (American Elm)

779 *Ulmus Thomasi* (Rock Elm)

flowers in racemes becoming longer than broad; fruits usually hairy on the side which covers the seed; lower surface of leaves generally remaining hairy d

d. Common in the Ozark region, often in dry and rocky places, but also in lowlands or along streams; leaf-stalks (petioles) usually 1–3 mm. (rarely to 5) long; base of leaf-stalk hairy on upper and lower sides; buds glabrous (without hairs) or nearly so; young branchlets often developing corky wings; fully grown leaves mostly 4–8 cm. (rarely 9) long, mostly 1–3 cm. (rarely 4) broad; fruits 3–5 mm. broad 3. *U. ALATA*

d. Rare, and chiefly outside of the Ozark area in northern, central, and extreme southeastern Missouri, along streams and wet woods; leaf-stalks (petioles) 3–10 mm. long; base of leaf-stalks glabrous (without hairs) on lower side; buds rather hairy; corky growth only on older branches; fully grown leaves mostly 8–15 cm. long, 3–9 cm. broad; fruits 9–15 mm. broad 2. *U. THOMASI*

1. ***Ulmus americana* L.** American Elm

Map 778

Also called White Elm
Flowers February–April.

Occurs usually along streams and low moist ground.
Throughout Missouri and doubtless in every county.

Ranges from Newfoundland to Saskatchewan,
south to Florida and Texas.

This species varies considerably in the pubescence
of the young branchlets and upper surface of leaves.

Fernald (Rh. 47: 132–33. 1945) has attempted to
account for these variations found by recognizing four
forms as follows:

Leaves smooth or smoothish above

Young branchlets pubescent. f. *PENDULA* (Ait.) Fern.

Young branchlets glabrous. . . f. *LAEVIOR* Fern.

Leaves harshly scabrous above

Young branchlets pubescent . f. *ALBA* (Ait.) Fern.

Young branchlets glabrous . f. *INTERCEDENS* Fern.

All four of these variations occur throughout Mis-
souri.

Since it has never been determined to which of
these the original Linnean specimen applies, it is at
present not possible to designate any one form as
typical f. *americana* as represented by the actual type
specimen of Linnaeus. In the present work, no sub-
divisions of the species are being maintained, pending

future realignment of the names used by Fernald.

In autumn the foliage turns yellow and eventually
orange brown. The wood has been used in many ways,
especially for wagon hubs, agricultural implements,
furniture, barrels, basket handles, flooring, ship-
building, boxes, and chopping bowls. It is also used
for the manufacture of fiber for roofing felt. The bark
was at one time made into ropes and ox whips, and
the Indians used the bark for construction of canoes.
The wood is unsatisfactory, however, for posts or fire-
wood because of its quick-rotting and water holding
properties.

The vase-like form of the tree has made American
Elm one of the most prized ornamental and shade
trees in the United States. Since 1930, when the first
outbreak of Dutch Elm disease was recorded in the
United States, ever increasing damage from this com-
bination fungus and beetle scourge together with the
phloem necrosis has taken its toll of this graceful
species. Some trees have been killed in Missouri, but
in general the diseases at the present time have affected
a relatively small percentage of elm in the state.

2. ***Ulmus Thomasi* Sarg.** Rock Elm Map 779

Also called Cork Elm

Flowers March–April.

Occurs in low wet or alluvial ground along streams
and in flood plain forest. Scattered in portions of

780 *Ulmus alata* (Winged Elm)

781 *Ulmus rubra* (Slippery Elm)

782 *Ulmus pumila* (Siberian Elm)

northern, central, and southeastern Missouri; absent from the Ozark and unglaciated prairie sections.

Ranges from Vermont and Quebec to Michigan, Minnesota, and South Dakota, south to New York, Ohio, Tennessee, Missouri, and Kansas.

The corky growth is limited to the older branches, and is sometimes poorly developed on the trees. The wood is tough, solid, and flexible, and these qualities have in the past given it some preference for such items as railroad ties, hubs of wagon wheels, various agricultural implements, framework of chairs, stock for other furniture, barrels, and ax handles. It is used as plywood in boxes and trunks.

3. *Ulmus alata* Michx. Winged Elm Map 780

Also called Wahoo (a name also applied to *Euonymus atropurpurea*).

Flowers February–March.

Occurs in dry rocky upland woods, borders of rocky glades, and in low ground of valleys, ravine bottoms, and along streams, generally in acid soils. Found in the Ozark region of southern and east-central Missouri, north to Lincoln, Callaway, Cooper, and Pettis counties, west to St. Clair, Lawrence, and Newton counties.

A specimen in the herbarium of William Jewell College from Clay County (river banks and ridges, woods along river, south of Liberty, May 6, 1948, *Shirley Landers 83*), is doubtfully identified as this species, and is not included on the distribution map. More material needs to be seen from this station before the status of the collection can be properly evaluated.

Ranges from Florida to Texas, north to Virginia. Kentucky, Indiana, Illinois, and Missouri.

This distinct species is common throughout most of the Ozark forests in either lowland or upland situations. It varies from a dwarf scrubby tree only several feet tall to one of fairly majestic proportions, up to 100 feet tall. The foliage turns a dull green and yellow in autumn.

The wood is difficult to split, but is used for such articles as hubs of wagon wheels, tool handles, and table legs. The inner bark has been employed as a rope to fasten together the covers of cotton bales.

4. *Ulmus rubra* Muhl. Slippery Elm Map 781

Ulmus fulva Michx. [P & S, Steyererm.]

Flowers February–April.

Occurs in dry upland or rocky woods, open wooded bluffs and along streams, generally commonest in limestone areas. Throughout Missouri, and doubtless in every county.

Ranges from Florida to Texas, north to Maine, Quebec, Ontario, Minnesota, and North Dakota.

The twigs are generally rough-pubescent, and usually more so than any of the other species of Missouri. The mucilaginous inner bark is sometimes chewed. It was used by some of the American Indian tribes as a food cooked with fat. It has been referred to as an emergency food, and the Kiowa Indians employ the bark as a tea. This bark has also been used in medicine as a demulcent in the treatment of fevers and inflammations.

The wood is easy to split, is strong and durable, and these qualities have seen it used for fence posts, railroad ties, window sills, wagon hubs, and agricultural implements.

5. *Ulmus pumila* L. Siberian Elm Map 782

Also called Dwarf Elm

Flowers March–April.

Often planted, and occasionally escaped from cultivation in St. Louis (along overpass of Kingshighway between Manchester Ave. and right-of-way of Mo. Pac. R.R., St. Louis, August 31, 1958, *Muehlenbach 1475*), Douglas, Newton (rocky waste ground along Hickory Creek, Neosho, October 19, 1953, *Palmer 57208*; *57218*), and McDonald (near Beaver Brook Spring, Anderson, October 19, 1954, *Palmer 52940*) counties.

Native of Asia; naturalized and escaped from cultivation from Minnesota to Kansas.

This tree is often collected in sterile condition. It is frequently planted in the central and western United States for shade, screen, windbreak, and shelter. It has sometimes been mistaken for and confused with the Chinese Elm, *Ulmus parvifolia* Jacq., a species which flowers in autumn, whereas *U. pumila* blossoms in the spring.

Excluded species

Ulmus serotina Sarg. September Elm, Red Elm

This species occurs in adjacent southern Illinois and northern Arkansas. It has thus far not been found in Missouri. False reports of the occurrence of this species in Missouri have been taken from the following mislabeled collection: The label on the specimen reads 'top of high rocky bluff of White River, opposite Cotter, in Marion Co., October 2, 1937, *Palmer 43881*,' and has 'Flora of Missouri' at the top of the label, but the collector forgot to replace 'Missouri' with 'Arkansas,' Cotter, Marion Co., being, of course, in Arkansas.

2. **Planera** J. F. Gmel Water Elm

Planera aquatica (Walt.) J. F. Gmel.

Water Elm

Map 783

Flowers March–April.

Occurs in swamps and low wet woodland of the southeastern lowland section, north to Mississippi and Wayne counties and west to Ripley County.

Ranges from Florida to Texas, north to North Carolina, Kentucky, Illinois, and Missouri.

The sexes are separate, the staminate or male flowers occurring in small clusters of last year's twigs, the pistillate on short slender stalks from the leaf-axils of the present season. The thin outside of the 1-seeded fruit has slender short rough appendages 1–3 mm. long.

The gray or light brown bark separates into large scales which reveal a reddish-brown inner bark.

3. **Celtis** L. Hackberry, Sugarberry

This genus is greatly in need of a complete revision. The limits of the species, as presently interpreted, leave unsolved many problems of variability and intergradations. The following treatment is based upon the work of Fernald, Deam, and Sargent.

- a. Leaves of both fruiting branches and leafy shoots with 10–40 teeth all around the margins except at very base, usually abruptly long-acuminate (long-pointed); mature fruits 8–11 mm. long, usually with a short beak, quite wrinkled in drying, purple-black to dark brown or orange-red; fruiting stalks (pedicels) usually much longer than the leaf-stalks (petioles); stone of fruit 7–9 mm. long

1. *C. OCCIDENTALIS*

- a. Leaves of fruiting branches without teeth or with few teeth on one or both margins (if many-toothed then uniformly green on both surfaces and only gradually long-pointed); leaves of vegetative (leafy) branches similar or with teeth nearly all around the margins; mature fruits 5–8 mm. long, without or nearly without a beak, not much wrinkled in drying, orange to cherry-red or brownish; fruiting stalks either shorter or slightly longer than leaf-stalks; stone of fruit 4.5–7 mm. long

b

- b. Shrub or small tree growing usually in dry, rocky, or exposed situations; leaves of fruiting branches $\frac{1}{2}$ – $\frac{3}{4}$ as broad as long, 2–8 cm. long, ovate, with either blunt, acute, or short-acuminate (short slender tip) summit, without or nearly without teeth, gray-green on both surfaces or darker above

2. *C. TENUIFOLIA*

- b. Usually medium to large trees of low wet bottomland along streams and in valleys, but also small trees on glades and bluffs; leaves of fruiting branches less than half as broad as long, 4–10 cm. long, narrowly lanceolate to lance-ovate or lance-oblong, tapering to a long slender tip, which is often falcate (curved to one side), either without teeth or conspicuously toothed, pale or dull green on both surfaces

3. *C. LAEVIGATA*

Plate no. 138. 1. *Ulmus Thomasi*, $\times \frac{2}{7}$; a. Fruiting branch; b. Flowering branch. 2. *Ulmus alata*, $\times \frac{2}{7}$; a. Fruiting branch; b. Flowering branch; Details from Small, The New York Botanical Garden. 3. *Ulmus rubra*, $\times \frac{2}{7}$; a. Flowering branch; b. Fruiting branch. 4. *Planera aquatica*, $\times \frac{2}{7}$; a. Flowering branch; b. Fruiting branch; Details from Small, The New York Botanical Garden.

783 *Planera aquatica* (Water Elm)784 • *Celtis occidentalis* var. *occidentalis* (Hackberry)
784 □ *Celtis occidentalis* var. *pumila*
784 x *Celtis occidentalis* var. *canina*785 • *Celtis tenuifolia* var. *tenuifolia* (Dwarf Hackberry)
785 □ *Celtis tenuifolia* var. *georgiana*

1. ***Celtis occidentalis* L.** Hackberry Map 784
Called Nettle Tree in some sections of Missouri.
Flowers April-May.

Occurs in low woods along streams and upland slopes. Throughout the state.

The variations of this species are ill-defined and as yet not satisfactorily worked out. Fernald's interpretation of the names (Rh. 50: 155-59. 1948) has been adopted in the present treatment. Intensive future work will be necessary to clarify further the present unsolved problems.

- a. Leaves rather thick (coriaceous), distinctly rough (scabrous) to the touch; fruit orange-red to dark brown, more or less spherical (globe-shaped), on stalks 3-15 mm. long . . .

1a. *C. occidentalis* var. *occidentalis*

- a. Leaves rather thin or membranaceous, smooth or nearly so to the touch; fruit blackish-purple or blackish or dark brown, ellipsoid-ovoid to ellipsoid-obovoid, on stalks mainly 8-35 mm. long b

- b. Sides of leaves strongly unequal, one side of the fully grown main leaves much broader and more strongly rounded, curved, or heart-shaped at base; leaves usually more than half as broad as long; the larger leaves of fruiting branches chiefly 3-9 cm. broad at the base . . . 1b. *C. occidentalis* var. *pumila*

- b. Sides of leaves nearly equal, the side which is slightly broader tapers gradually to a more wedge-shaped, straighter-sided, or only slightly rounded base; leaves usually less than half as broad as long; the larger leaves of fruiting branches chiefly 1.5-5 cm. broad at the base . . . 1c. *C. occidentalis*

var. *canina*

1a. ***Celtis occidentalis* var. *occidentalis***

Map 784

Celtis occidentalis var. *crassifolia* (Lam.) Gray [BB, P & S, Steyererm., Deam]

Celtis occidentalis L. [G]

Throughout Missouri and very common.

Ranges from Massachusetts to Idaho, south to Florida, Tennessee, Arkansas, and Oklahoma.

1b. ***Celtis occidentalis* var. *pumila*** (Pursh) Gray
Map 784

Celtis occidentalis of auth. [P & S, Steyererm., Deam], not L.

Celtis pumila Pursh, not auth.

Throughout Missouri, apparently less common than the two other variations.

Ranges from Quebec to North Dakota, south to Georgia, Alabama, Arkansas, and Oklahoma.

1c. ***Celtis occidentalis* var. *canina*** (Raf.) Sarg.

Map 784

Throughout Missouri, apparently the most common variation in the state.

Ranges from Quebec to Utah, south to Georgia, Tennessee, Missouri, and Oklahoma.

The foliage of *C. occidentalis* turns pale yellow in autumn. Some authorities consider this species the most important one of the genus, so far as investigated, in causing some cases of hay fever. On account of being commonly infected by a 'witches'-broom,' this species is not recommended as a street tree. The pale yellow or yellowish-white wood has good bending qualities, for which it is sometimes used for barrel hoops. It is also used for making into cabinets, cheap furniture, fence posts, boxes, and crates.

A powder obtained from the dried mashed-up stones of the fruit is reported to be used as an article of seasoning by Indians of the Dakotas. Mature frost-ripened fruits are edible, their thin pulp faintly suggesting the taste of date fruits, although much less sweet.

2. **Celtis tenuifolia** Nutt. Dwarf Hackberry
Map 785

Flowers April–May.

Missouri material is represented by the following two variations:

- a. Upper leaf-surface smooth; lower leaf-surface glabrous or sparsely hairy; leaves rather thin; leaf-stalks (petioles), fruiting-stalks (pedicels), and branchlets glabrous or sparsely hairy .

2a. *C. TENUIFOLIA* var. *TENUIFOLIA*

- a. Upper leaf-surface harshly scabrous (rough); lower leaf-surface densely or more conspicuously hairy; leaves thick and rather stiff; leaf-stalks, fruiting-stalks, and branchlets more densely hairy . 2b. *C. TENUIFOLIA* var. *GEORGIANA*

2a. **Celtis tenuifolia** var. **tenuifolia** Map 785

Celtis tenuifolia Nutt. [G, BB in part]

Celtis pumila of auth. [P & S, Steyer., Deam], not Pursh

Celtis pumila var. *Deamii* Sarg. [P & S, Steyer., Deam]

Occurs in rocky open woods, borders of glades and along bluffs. Southern and central Missouri north to Pike, Pettis, and Jackson counties; less common than the var. *georgiana* in Missouri.

Ranges from Florida to Louisiana, north to Pennsylvania, Virginia, Indiana, and Missouri.

2b. **Celtis tenuifolia** var. **georgiana** (Small)

Fern. & Schub. Map 785

Celtis pumila var. *georgiana* (Small) Sarg. [P & S, Steyer.]

Occurs in rocky open woods, glades, and on bluffs. Common throughout the Ozark section north to Ralls, Monroe, Cooper, Lafayette, and Vernon counties; absent from the lowlands of southeastern Missouri.

Ranges from Georgia to Louisiana and Oklahoma, north to Virginia, Kentucky, Indiana, Missouri, and Kansas.

Specimens from Iron and St. Francois counties, previously treated by Palmer and Steyermark as *C. pumila* var. *Deamii* in their *Annotated Catalogue* are referred in the present work to *C. tenuifolia* var. *tenuifolia* and var. *georgiana*. Deam (*Trees of Indiana*, 2nd revised ed. 160. 1932, and *Fl. Ind.* 394. 1940) considered this variety as synonymous with typical *C. pumila* = *C. tenuifolia* var. *tenuifolia*. While Palmer 19510 and 18119 from Iron Co., both labeled by Palmer *C. pumila* var. *Deamii* in the Gray Herbarium material, may be referred to *C. tenuifolia* var. *tenuifolia* because of the nearly glabrous, thinner leaves which are smooth above, nevertheless Palmer 18051 from St. Francois Co. and Palmer 18095 from Iron Co., also in the Gray

Herbarium and identified there as *C. pumila* var. *Deamii*, have the petioles and branchlets more pubescent and may be referred rather to *C. tenuifolia* var. *georgiana*.

This species varies from a dwarf stunted shrub a few feet tall to a tree up to 8 meters. It usually is found in the most exposed rocky sections on top of limestone bluffs and escarpments or bordering limestone glades, where it is frequently associated with *Bumelia lanuginosa* var. *oblongifolia*, *Viburnum rufidulum*, *Diospyros virginiana*, *Ulmus alata*, and *Rhus aromatica* var. *serotina*, forming with these one of the earlier stages in forest succession over a limestone glade area.

The fruit varies from orange to light cherry red in late summer to a darker cherry-red in fall.

3. **Celtis laevigata** Willd. Sugarberry Map 786

Also known as Southern Hackberry

Flowers April–May.

Missouri material is quite variable and represented by the following variations:

- a. Leaf-stalks usually hairy; leaves thick (coriaceous), without teeth on the margins; upper leaf-surface rough (scabrous) to the touch .

3c. *C. LAEVIGATA* var. *TEXANA*

- a. Leaf-stalks usually glabrous (without hairs); leaves thin and membranaceous or nearly so, with or without teeth on the margins; upper leaf-surface smooth or sparsely hairy . . . b

b. Margins of leaves without teeth . . .

3a. *C. LAEVIGATA* var. *LAEVIGATA*

b. Margins of leaves with numerous teeth .

3b. *C. LAEVIGATA* var. *SMALLII*

3a. **Celtis laevigata** var. **laevigata** Map 786

Celtis laevigata Willd. [G, P & S, Steyer.]

Celtis occidentalis var. *integrifolia* Nutt.

Occurs in low wet or alluvial soils along streams and flood plains, rarely on higher rocky ground in southern and central Missouri mostly outside the Ozark region, north to Marion County on the east and Andrew County on the west. At the Andrew County station (Steyermark 84519), it occupies the upper exposed portion of rocky west-facing limestone slopes bordering the valley of One Hundred and Two River, T59N, R35W, SW $\frac{1}{4}$ sect. 7, SE $\frac{1}{4}$ sect. 12, 3 mi. east of Savannah.

Ranges from Florida to Texas and Mexico, north to Virginia, Kentucky, Indiana, Illinois, Missouri, and Oklahoma.

3b. **Celtis laevigata** var. **Smallii** (Beadle) Sarg.

Map 786

Occurs in low wet or alluvial soils along streams

and flood plains. Known only from Marion, Pemiscot, and Jackson counties.

Ranges from Florida to Louisiana, north to Virginia, Kentucky, Illinois, and Missouri.

3c. *Celtis laevigata* var. *texana* Sarg. Map 786
Celtis reticulata [of Steyermark.], not Torr.

Occurs in rocky open woods, glades, and bluffs. Common throughout the Ozark region in southern and central Missouri north to Pike, Montgomery, Callaway, Boone, Pettis, and Jackson counties.

Ranges from Illinois, Missouri, and Kansas, southwest to Texas and New Mexico.

An especially thick- and reticulate-leaved specimen from St. Clair Co. (dominant on limestone glade on headlands of Osage River, $3\frac{1}{2}$ mi. north of Iconium, T39N, R24W, sect. 10, August 8, 1937, *Steyermark 24397*) was originally identified as *C. reticulata* Torr. and accepted by Palmer and Steyermark (*Ann. Mo. Bot. Gard.* 25: 780. 1938) and by Steyermark (*Spring Flora*, p. 148. 1940). Despite the unusually rugose-reticulate leaves, however, a re-examination of the specimen would seem to place it better in *C. laevigata* var. *texana*.

These variations grade into one another, and are not distinct. Trees with the scabrous leaves of var.

texana but the thinner leaves of var. *laevigata*, and other similar non-correlations occur. Moreover, there is frequently great difficulty in distinguishing the thick scabrous, more or less entire leaves of *C. laevigata* var. *texana* from similar leaves of *C. tenuifolia* var. *georgiana*, especially since the two varieties may occupy the same type of rocky exposed habitat. Much field work remains to be done to clarify the problems of intergradation and variation not only within *C. laevigata*, but between the var. *texana* and *C. tenuifolia* and var. *georgiana*. As a lowland tree with thin, relatively narrow, and entire leaves, *C. laevigata* var. *laevigata* is fairly constant. As it occupies drier and more exposed situations as var. *texana* it becomes less clearly marked. Deam (*Fl. Ind.* pp. 393-94. 1940) believes that the thickening of the leaves in *C. laevigata* may be due to growing in an open situation.

Birds eat the fruit of this and other species of *Celtis*, and in autumn the mature fruits secrete a sweet sticky substance attractive to mealy bugs. The wood is used for similar purposes as that of *C. occidentalis*. Since this species is quite resistant to the witches'-broom infection, it is recommended as a street tree in the southern states, where it may be seen in wide use.

MORACEAE (Mulberry Family)

- a. Leaf compound, divided into 3-7 separate, narrow, toothed leaflets; erect herb 4. CANNABIS
- a. Leaf simple, unlobed or deeply lobed, but not divided into separate leaflets; tree, shrub, or vine. b
- b. No teeth on leaf-margin; stout thorns 1-2 cm. long usually present on branches 3. MACLURA
- b. Teeth present on leaf-margins; no thorns on branches c
- c. Stems vining, sprawling, or spreading along the ground; plants with watery juice; rough hairs on stem and leaf-stalks (petioles) pointed downward (with reference to tip of stem). 5. HUMULUS
- c. Trees or shrubs with milky juice; branches and leaf-stalks when hairy without rough downward-pointing hairs d
- d. Midrib of upper leaf-surface with noticeably longer hairs as compared with other hairs; lower surface of leaf soft-hairy with dense long hairs; leaf-stalks (petioles) 3-10 cm. long, they and young branches with long hairs; 2-3 scales to each bud; female catkins and fruit ball-shaped (globose); bark of tree smooth 2. BROUSSONETIA
- d. Midrib of upper leaf-surface without noticeably longer hairs as compared with other hairs; lower surface of leaf smooth or with short hairs; leaf-stalks (petioles) 1.5-3 cm. long, they and young branches either without hairs or with short hairs closely pressed to the stem; 3-6 scales to each bud; female catkins and fruit short-cylindric; bark of tree scaly or furrowed 1. MORUS

1. *Morus* L. Mulberry

Occasional cases of hay fever have been traced to species of this genus which shed large quantities of pollen.

- Lower surface of leaf hairy between the main nerves 1. *M. RUBRA*
Lower surface of leaf without hairs, or, if hairs are present, they are along midrib or main nerves or as small tufts in the axils of main nerves 2. *M. ALBA*

1. *Morus rubra* L. Red Mulberry Map 787
Flowers April–May.

Occurs in rich woods, or open rocky places, either in lowland or upland, along roadsides, fields, and pastures. Known from every county in Missouri.

Ranges from Florida to Texas, north to Vermont, New York, Ontario, Minnesota, and South Dakota.

The foliage turns pale or dull green to greenish yellow in autumn. It is quite variable, ranging from unlobed to deeply lobed, and from rough-hairy to glabrous on the upper surface. Leaves with glabrous upper surfaces are often mistaken for those of *M. alba*.

The sweet reddish to dark purple fruits attract many birds, especially robins and cedar waxwings, and squirrels. They are made into jellies, jams, pies, as well as served for refreshing drinks, or are frequently eaten just as fresh fruit.

The wood is light in weight and quite durable, used for fence posts, barrels, boat building, and farm tools. As in various tropical Central and South American countries, where the Indians employed the bark of certain genera of the Mulberry family for cloth, so some of the Indian women of Mississippi and Louisiana at one time used the bark of this tree as an outer robe.

2. *Morus alba* L. White Mulberry Map 788
Flowers April–May.

Escaped from cultivation and commonly found in low wet ground along streams and stream banks, and along fence rows and pastures. Scattered throughout

Missouri, most frequently found naturalized in northern and central Missouri, with few records known from the Ozark region.

Native of eastern Asia; naturalized in various parts of the United States from New York southward.

The species is extremely variable and many forms are in cultivation. Only the following are known to have escaped from cultivation in Missouri:

- a. Leaves deeply and rather regularly divided into narrow long-pointed lobes . . . 2c. *M. ALBA* var. *ALBA* f. *MACROPHYLLA*
- a. Leaves unlobed or lobed, but not regularly cut into narrow long-pointed lobes . . . b
- b. Leaves chiefly 15–22 cm. long, not lobed 2b. *M. ALBA* var. *ALBA* f. *SKELETONIANA*
- b. Leaves mainly 6–15 cm. (up to 18) long, lobed or unlobed . . . 2a. *M. ALBA* var. *ALBA* f. *ALBA*

2a. *Morus alba* var. *alba* f. *alba* Map 788
This is the common form found naturalized in Missouri.

2b. *Morus alba* var. *alba* f. *skeletoniana* (Schneider) Rehder Map 788
Morus alba var. *laciniata* Beissn. [Bailey]

Known only from Jasper County, southwestern Missouri (open ground along roadway, Webb City, October 4, 1954, *Palmer 59051*; October 18, 1954, *Palmer 59163*).

789 *Broussonetia papyrifera* (Paper Mulberry)790 *Maclura pomifera* (Osage Orange)791 *Cannabis sativa* (Hemp)

2c. ***Morus alba* var. *alba* f. *macrophylla*** (Loud.)
Schneider Map 788

Morus alba f. *macrophylla* (Loud.) Schneider

Morus alba var. *macrophylla* Loddiges ex Loud.

Known only from Lawrence County, southwestern Missouri (along rocky bluffs of Clear Creek, Pierce City, August 22, 1950, Palmer 50832).

Some of the leaves on this specimen are only 13–15 cm. long.

Found commonly cultivated, but without records of their having become naturalized, are *M. alba* var. *pendula* Dipp., the Weeping Mulberry, the Texas form of which originated at the Texas Nursery of Carthage, Missouri, in 1883, with long hanging

branches and usually small lobed leaves; and *M. alba* var. *tatarica* (L.) Loudon, or Russian Mulberry, a small, bushy-headed tree with small usually lobed leaves 4–8 cm. long and a small red or purple, rarely whitish, fruit about 1 cm. long. In *M. alba* var. *alba* f. *alba* the fruit is somewhat longer, 1–2.5 cm. long and mostly whitish or pinkish.

The fruit is an attractive morsel to birds and people alike. *Morus alba* is the species upon whose leaves the caterpillar of the silkworm moth feeds, and, upon whose production the silk of commerce depends. The young leafy shoots of this species are used in Asia as a cooked vegetable.

2. ***Broussonetia* L'Her.** Paper Mulberry

***Broussonetia papyrifera* (L.) Vent.**

Paper Mulberry Map 789
Flowers April–May.

This is commonly planted as a shade tree in the lowland section of southeastern Missouri and occasionally is found naturalized there in Stoddard, Butler, and Dunklin counties, and also in St. Louis and Johnson counties. Probably more widely naturalized in the southern part of the state.

Native of Asia; introduced in the United States where naturalized from New York to Missouri and southward.

The irregularly lobed leaves greatly resemble those of *Morus*, but may be distinguished by the longer softer pubescence on the lower surface and the longer hairs of the midrib of the upper surface. In the Far East the bark has been used for centuries in paper-making, and the Pacific island natives make a cloth from the inner bark, known as Tapa cloth. A kind of glue is made from the sap by the Polynesian islanders.

The pollen of this tree is known to be responsible for some hay fever cases.

3. ***Maclura* Nutt.** Osage Orange

***Maclura pomifera* (Raf.) Schneid.**

Osage Orange Map 790

Known also as Bois-d'Arc or Bodark, Bowwood, and Hedge Apple.

Flowers May–June.

Occurs commonly in low alluvial woods in valleys, along streams, borders of woods, pastures, fence rows,

and in thickets. Throughout Missouri, doubtless in every county.

The tree is native to Arkansas, Oklahoma, and Texas, and perhaps Louisiana, but is believed to be introduced and naturalized in Missouri and elsewhere north to southern New England, New York, Ohio, Indiana, Illinois, and Iowa.

This tree was formerly widely planted in Missouri and other central states as a living fence, for which it is admirably suited by virtue of its stout thorns, and as a windbreak, but is now being replaced in many sections by living fences of *Rosa multiflora*.

The wood is exceptionally hard and the most durable of any of the woods used for fence posts at which it excels. Formerly, it supplied wood for wheel-stock and railroad ties. The bark was at one time used for tanning leather, and the orange roots and inner bark were used as a yellow dye. The Indian tribes of Arkansas, Oklahoma, and adjacent states at one time used the strong wood for bows and tomahawks.

This tree, called by the French Bois d'Arc, or Bowwood, is the one responsible for the name Ozark applied to the Missouri and Arkansas hills, the land

of the Bois d'Arc or Bodark or Bowwood. The foliage remains green long after most trees have turned color, but eventually in late autumn turns an orange-lemon, light yellow, or greenish-yellow color. The orange-shaped fruits, which start falling in October, are at first green, turning yellow. They are sometimes eaten by squirrels, opossums, and other animals. The fruit is reputed to have insect-repellent properties, for which it is recommended to place a few in the basement and in closets, or in rooms infested with roaches or waterbugs.

Occasional cases of hay fever are reported as caused by the pollen of this wind-pollinated tree, while some cases of dermatitis are occasionally caused by contact with the milky sap contained in the leaves, branches, and fruits.

4. *Cannabis* L. Hemp, Marijuana

***Cannabis sativa* L.** Hemp, Marijuana Map 791
Flowers June–October.

Occurs most commonly in rich fertile alluvial ground of river flood plain and valley bottoms frequently near streams, also in open and waste ground. Common in the northwest quarter of the state, where frequent in the Missouri River bottoms, and scattered elsewhere in central and western Missouri, south to St. Louis, Franklin, Boone, Howard, Saline, and Cass counties, locally south in Greene and Jasper counties; absent from the Ozark and southeastern lowland sections. Large sections of vacant lots in St. Louis, Kansas City, and other large towns, are sometimes seen populated with this plant, especially in low ground.

Native of Asia; introduced into North America, where naturalized from Quebec to British Columbia and southward.

This plant has the male and female flowers separated on distinct plants. These plants, when found, usually occur in large stands, with an aspect similar to that of Giant Ragweed or Horseweed (*Ambrosia trifida*). In fact, both are annuals, often 6 or more feet tall, and occupy similar habitats along river flood plains.

Both also cause hay fever, *Cannabis* pollen being considered an important cause in those regions, such as Nebraska, where it is abundant and constitutes 17 per cent of the pollen contained in the air in late summer and fall.

The strong fiber of the plants is made into many kinds of paper, one of its early uses. At present most of the commercial use of the fiber is for rope, sacks, twine, cloth, caulking material, packing, and cordage. Hemp seeds are often found in bird seed mixtures for wild bird food, and in parts of Europe the parched seeds are sometimes eaten by native folk in cakes or fried. The upper leaves and flower parts and seeds from the female plant, when dried, are the source of a drug originally employed in medicine for relieving pains and treating nervous ailments. This same drug became used as a narcotic in liquid form or smoked as *hashish*. It entered the cigarette trade as *marijuana*, and because the smoking of it in excess produces serious effects on its victims, it is prohibited from use. In the United States it can be grown under special government permit only for certain uses. The seeds yield a drying oil used for soaps, paints, and varnishes, and as an illuminating oil.

PLATE NO. 140

792 *Humulus Lupulus* (Hops)

793 *Humulus japonicus* (Japanese Hops)

794 *Urtica dioica* var. *procera* (Tall Nettle)

5. *Humulus* L. Hops, Hop

The wind-blown pollen from the male plants of species of *Humulus* is sometimes thought to be responsible for cases of hay fever.

The large main leaves with usually 3 lobes (but sometimes all the leaves on the young stems or on the upper part of stem without any lobes); leaf-stalk (petiole) mainly shorter than or equaling the leaf-blade; bracts of the female flowers not hairy on the margins, not green, and with little glands at the base; upper bracts of female inflorescence blunt; bracts of female inflorescence in fruit becoming broad, rounded and covering the seed-like fruits; anthers of the male flowers without glands 1. *H. LUPULUS*
The large main leaves with usually 5-7 lobes; leaf-stalk (petiole) chiefly longer than the leaf-blade; bracts of the female flowers conspicuously long-hairy on the margins (ciliate), green, and usually lacking little glands at the base; all bracts of the female inflorescence conspicuously long-pointed (acuminate); bracts of female inflorescence in fruit narrow, long-pointed, and narrower than the seed-like fruits; anthers of the male flowers with glands 2. *H. JAPONICUS*

1. ***Humulus Lupulus* L.** Hops Map 792
Humulus americanus Nutt. [Bailey, Deam]
Flowers July-August.

Occurs in fertile, open, and waste ground, fence-rows, shaded thickets and wooded slopes on bluffs or at the base of bluffs, and along railroads. Found throughout Missouri in most counties, but not recorded from most of the lowland counties of south-eastern Missouri.

Widely distributed from Nova Scotia to Manitoba, Montana, and California, south to North Carolina, Ohio, Kentucky, Illinois, Missouri, Arkansas, Oklahoma, New Mexico, and Arizona. Also in Europe and Asia.

The American plant has been considered by Bailey and some authors as a distinct species, *H. americanus* Nutt., with a western variety, but the characters used for separating it from *H. Lupulus*, mainly referring to the apex of the leaf lobes, the fineness of their tothing, and the relative amount of glands present on the lower surface of the leaves, do not appear to be reliable criteria.

This species is widely known for its use in the brewing industry, which employs the aromatic glandular female inflorescences to give beer its bitter taste and to prevent decay from bacterial processes during

stages of formation. Hops also play a role medicinally, being used to relieve pain and induce sleep. The discarded remains of the hops are sometimes used as a mulch for rose-beds and shrubs. The very young shoots can be cooked as a vegetable, and are claimed to have unusual flavor.

In some rural communities, before the common use of commercial yeast, hops were used for breadmaking: a handful of hops was boiled in a pint of water. To this was added potatoes which were boiled until tender, then mashed and thickened with corn meal. The whole mass was then flattened and cut into squares to dry. Such squares were stored as yeast cakes and were ready in 3 or 4 days for use in breadmaking.

2. ***Humulus japonicus* Sieb. & Zucc.**
Japanese Hops Map 793
Humulus scandens (Lour.) Merr. [Bailey]
Flowers July-October.

Occurs in open ground, along railroads, and waste places. Scattered and rare, as an escape from cultivation; known only in St. Louis, Schuyler, Jackson, and Jasper counties.

Native of eastern Asia; introduced into the United States, where naturalized from New England to Michigan, south to Virginia and Missouri.

URTICACEAE (Nettle Family)

- a. No teeth on leaf-margins 5. *PARIETARIA*
- a. Teeth present on leaf-margins *b*
 - b. Leaves alternate 2. *LAPORTEA*
 - b. Leaves opposite *c*
 - c. Plant completely without hairs 4. *PILEA*
 - c. Plant with hairs on some part of stem, leaf, flower, or fruit *d*
 - d. Plants with stinging hairs; female flowers with 4 separate sepals; inflorescence of loosely interrupted unbranched clusters shorter than the leaf-stalks (petioles), or, if longer than the leaf-stalks, the flower-clusters are in forked, branched, or loosely-flowered inflorescences with broad intervals of space between the flower-clusters; stigma of female flowers globe-shaped, without a definite style 1. *URTICA*
 - d. Plants lacking stinging hairs; female flowers with the sepals united into a tubular or cup-shaped calyx; inflorescence a simple elongated spike of densely crowded clusters, the whole inflorescence longer than the leaf-stalks (petiole); style of female flowers long and thread-like with the stigmatic portion along one side 3. *BOEHMERIA*

1. *Urtica* L. Nettle

- a. Stem without spreading hairs; main leaves of the stem 7.5–15 cm. long, more than twice as long as broad; tall perennials with tough stems, mainly 9–21 dm. tall; stipules erect, 5–15 mm. long; flower-clusters branched, usually longer than the leaf-stalks (petioles) 1. *U. dioica* var. *procera*
- a. Stem with noticeable spreading hairs; main leaves of the stem 1.5–7.5 cm. long, as broad as long to about twice as long as broad; annuals with soft or slender stems, 1–8 dm. tall; stipules spreading or turning down, 1–3 mm. long; flower-clusters unbranched, usually shorter than the leaf-stalks (petioles) *b*
 - b. All leaves about the same size from base to tip of plant; margins of leaves saw-toothed, the teeth sharp-pointed, triangular, straight-sided 2. *U. urens*
 - b. Upper leaves noticeably smaller than middle or lower ones; margins of leaves wavy-toothed (crenate-serrate), the teeth blunt, the sides curved (convex) 3. *U. chamaedryoides*

1. *Urtica dioica* L. var. *procera* (Muhl.) Wedd.
Tall Nettle Map 794
Urtica procera Muhl. [G, P & S, Steyerma.]
Flowers May–October.

Occurs commonly in low alluvial bottoms of river valley and flood plain, bordering streams, and in cultivated and waste ground. Northern and central Missouri mainly along the larger streams and south to Cape Girardeau, Gasconade, Moniteau, Pettis, Bates, and Jasper counties.

Ranges from Newfoundland to British Columbia, south to North Carolina, Louisiana, and New Mexico.

The upper portion of the stem is short hairy. Many of the Missouri specimens have the lower surface of the leaf-blades glabrous or nearly so and the pairs of teeth often range between 13–23, which, according to Fernald's treatment in the eighth edition of *Gray's Manual*, would place the Missouri material in *U. gracilis* Ait., a species of more northerly range. However, as Dr. Hermann has demonstrated (Am. Midl. Nat. 35: 773–78. 1946), Fernald's separation of the perennial species of *Urtica* in the United States east of the Rocky Mountains into four separate species is based largely on assumed and quantitative differences which are not constant and frequently cannot be correlated.

The present treatment is in agreement with Dr. Hermann's conclusions.
Young shoots of this species, when boiled, are reported to serve as a cooked vegetable, somewhat similar to spinach.

2. *Urtica urens* L. Dwarf Nettle Map 795
Also called Burning Nettle.
Flowers May–September.

Known only from Clark and Jackson (waste ground, Courtney, May 13, 1930, *Bush 11707, 11707A*) counties.

Native of Europe and Asia; introduced in North America, where ranging from Newfoundland to British Columbia, south to New York, Pennsylvania, West Virginia, Illinois, Missouri, and California.

The stiff, brittle hairs of this and other species of the genus, when coming into contact with the skin, produce an itching for a short time. The young leaves of this and other species of nettles may be boiled and eaten as a vegetable.

3. *Urtica chamaedryoides* Pursh Nettle Map 796
Flowers April–September.

795 *Urtica urens* (Dwarf Nettle)796 *Urtica chamaedryoides* (Nettle)797 *Laportea canadensis* (Wood Nettle)

Occurs in low rich woods in alluvial ground and along slopes bordering streams, or in open low ground. Southwestern Missouri from McDonald to Taney counties, and locally east in Pemiscot County, southeastern Missouri. The stations along White River,

previously occupied by this species, have now been destroyed by the impoundment of Table Rock Dam.

Ranges from Florida to Texas and Mexico, north to West Virginia, Kentucky, Missouri, and Oklahoma; locally north in Massachusetts.

2. *Laportea* Gaud. Wood Nettle

Laportea canadensis (L.) Gaud.

Wood Nettle

Map 797

Flowers May 30–August.

Occurs in wet or rich low woodland, in valleys and along streams, where it usually forms extensive stands. Throughout Missouri, and doubtless in every county.

Ranges from Nova Scotia and Quebec to Manitoba, south to Florida, Alabama, Mississippi, Missouri, and Oklahoma.

This nettle is, by far, the one of greatest concern

and nuisance to anyone tramping the wooded valleys of Missouri during summer and autumn. As it usually occurs in extensive stands over large areas, it is difficult to avoid or detour around, and thick pants are strongly recommended. The stinging hairs, which break off at only slight contact, produce an intense itching sensation which lasts for several minutes. It does not compare in severeness, however, with some of the really irritating hairs of tropical american Urticaceae (*Urtica* spp.) or Euphorbiaceae (*Cnidoscolus*).

3. *Boehmeria* Jacq. False Nettle

Boehmeria cylindrica (L.) Sw. False Nettle

Map 798

Flowers June–October.

Occurs in swampy low spring-fed meadows, along spring branches and borders of small streams, and low wet woods.

Missouri material is represented by two variations:

Leaf-stalks (petioles) of the middle leaves usually (20–) 25–90 mm. long; tip of leaf long acuminate; leaves not folded, flat, spreading to ascending; stem mostly glabrous; fruiting achenes without purple marks, without hairs on the main body;

upper surface of leaves smooth to slightly rough (scabrous); lower surface of leaves mostly without hairs or only slightly hairy B. CYLINDRICA

var. CYLINDRICA

Leaf-stalks (petioles) of the middle leaves 3–20 mm. (rarely 25) long; tip of leaf shorter-pointed; some of leaves more or less folded and drooping; stem generally more pubescent; fruiting achenes marked with purple, with hooked hairs on body and wings; upper surface of leaves usually rough (scabrous); lower surface of leaves usually hairy

B. CYLINDRICA var. DRUMMONDIANA

Plate no. 141. 1. *Laportea canadensis*, $\times \frac{2}{7}$. 2. *Boehmeria cylindrica* var. *cylindrica*, $\times \frac{2}{7}$; After Gleason, The New York Botanical Garden. 3. *Pilea pumila*, $\times \frac{2}{7}$; After Gleason, The New York Botanical Garden. 4. *Parietaria pensylvanica* var. *pensylvanica*, $\times \frac{2}{7}$. 5. *Phoradendron flavescens*, $\times \frac{2}{7}$; a. Inflorescence, $\times \frac{1}{7}$; b. Fruiting branch, $\times \frac{2}{7}$. 6. *Asarum canadense*, $\times \frac{2}{7}$; a. Flowers with spreading and recurved perianth segments. 7. *Comandra Richardsiana*, $\times \frac{2}{7}$; a. Flower, $\times \frac{1}{7}$. 8. *Aristolochia Serpentina*, $\times \frac{2}{7}$; a. Flower, side and front view, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden.

PLATE NO. 141

798 • *Boehmeria cylindrica* var. *cylindrica* (False Nettle)
798 □ *Boehmeria cylindrica* var. *Drummondiana*

799 *Pilea pumila* (Clearweed)

800 • *Parietaria pensylvanica* var. *pensylvanica* (Pellitory)
800 □ *Parietaria pensylvanica* var. *obtusata*

Boehmeria cylindrica* var. *cylindrica Map 798

This is the common variation in the state, occurring throughout southern, central, and eastern Missouri north to Clark, Scotland, Adair, Linn, Livingston, Clay, and Platte counties.

Ranges from Florida to Texas, north to Maine, Quebec, Ontario, and Minnesota.

Boehmeria cylindrica* var. *Drummondiana

Wedd. Map 798

This variety is limited to moist thickets, spring branches and swampy open meadows fed by spring branches issuing from calcareous rocks in the Ozark section of southern Missouri, north to Bollinger,

Reynolds, Shannon, Howell, and Jasper counties. Probably of wider distribution within the Ozarks.

Ranges from Florida to Texas, north to Massachusetts, New York, Michigan, Illinois, Missouri, and Nebraska.

This variety is found in generally more exposed situations than var. *cylindrica* and frequents calcareous swampy habitats where the soil is quite alkaline. Deam (*Fl. Ind.* p. 401. 1940) likewise noted an affinity of the var. *Drummondiana* for alkaline soils in Indiana. While the varieties show various stages of intergradation, for the most part they appear to be satisfactorily separated by the characters indicated in the key.

4. ***Pilea* Lindl. Clearweed**

***Pilea pumila* (L.) Gray Clearweed** Map 799

Pilea pumila var. *Deamii* (Lunell) Fern. [G]

Flowers July–October.

Occurs in rich low or alluvial ground in wooded valleys, and wet woodland along streams and ponds. Throughout Missouri and doubtless in every county.

Ranges from Quebec to Ontario and Minnesota, south to Florida, Louisiana, and Texas.

Both var. *pumila* and var. *Deamii* occur in Missouri, but the numerous intermediate specimens found between the two variations and lack of correlation and inconstancy of characters, as reported by Deam in Indiana (*Fl. Ind.* pp. 399–400. 1940), apply similarly to all the material examined in Missouri.

Another species, *P. fontana* (Lunell) Rydb., which has not yet been found in Missouri, but approaches

the state's borders, is distinguished from *P. pumila* by the blackish instead of green, purplish, or straw-colored fruits with whitish margins, pericarp (outer covering) purplish within, instead of whitish or pale brown, relatively shorter petioles (generally 1/5–1/2 length of leaf-blade), and fewer teeth (generally 4–9) on each side of the leaf-blade.

The clear, translucent plants of Clearweed are often used in biology classroom experiments to demonstrate the passage of liquids upward from the lower part of the stem to the petioles and leaf-blades. The colored liquid used, often red eosin, is clearly visible through the plant's watery cells. The plant has been suggested, because of its succulence, as a possible source for greens as a cooked vegetable, but no records indicate its definite use for such purposes.

5. ***Parietaria* L. Pellitory**

***Parietaria pensylvanica* Muhl. Pellitory** Map 800

Flowers May–October.

Occurs in open or rocky, often dry woodland, along bluffs, on glades, in thickets, and in moist open

801 *Phoradendron flavescens* (Mistletoe)

802 *Comandra richardsoniana* (Bastard Toadflax)

803 *Asarum canadense* (Wild Ginger)

ground; frequents limestone areas, but also in other types of soils. Throughout Missouri, but absent from most of the lowland counties of the extreme south-eastern section.

Missouri material is represented by two variations:

Bracts which are at base of flowers of well-developed plants 2-3 times length of fully grown calyx; stem with a minute hairiness of mostly curled or hooked hairs or these mixed with a few straight and longer hairs; middle and upper leaf-blades oblong-lanceolate, long-pointed, up to 7 cm. long.

a. *P. PENSYLVANICA* var. *PENSYLVANICA*

Bracts which are at base of flowers of well-developed plants about as long as or shorter than the length of fully grown calyx; stem with a denser hairiness of a few to many straight and long hairs mixed with short spreading and hooked ones; middle and upper leaf-blades broadly ovate or ovate-oblong, often more blunt at tip, up to 4 cm. long.

b. *P. PENSYLVANICA* var. *OBTUSA*

a. ***Parietaria pensylvanica* var. *pensylvanica*** Map 800
This is the common variation, occurring throughout the state as indicated above.

Ranges from Florida to Texas and Mexico, north to Maine, Quebec, Ontario, Minnesota, Montana, and British Columbia.

b. ***Parietaria pensylvanica* var. *obtusa*** (Rydb.) Shinnery Map 800
Parietaria obtusa Rydb. [G, P & S]

Known only from Ozark County, southern Missouri (shaded ledges, dolomite bluffs of North Fork of White River, near Tecumseh, October 8, 1927, Palmer 32949).

Ranges from Missouri and Rocky Mountain region, south to Texas and Mexico.

I agree with Shinnery's interpretation that the intergradation between *P. obtusa* and *P. pensylvanica* makes it impossible to maintain *P. obtusa* as more than a variety (Field & Lab. 18: 42. 1950).

Order **SANTALES**

Fam. **LORANTHACEAE** (Mistletoe Family)

Phoradendron flavescens (Pursh) Nutt. Mistletoe Map 801

Phoradendron serotinum (Raf.) M. C. Johnston var. *serotinum* [Shinnery]

Flowers March-August; fruits September-January. Occurs in low woods in valleys and along streams, in southern Missouri, northeast in the southeastern lowland section to Cape Girardeau and Wayne counties, north and west along the St. Francis, Black, Eleven Points, and Current Rivers to Reynolds, Shannon, and Oregon counties, and then west in the White River and North Fork section of the southwestern part of the state in Ozark, Taney, and Stone counties; in

the latter three counties now nearly exterminated because of the impoundments from Norfork, Bull Shoals, and Table Rock dams.

Ranges from Florida to Texas, north to New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Missouri, and Kansas.

This well-known Christmas symbol is a parasite on only certain deciduous trees in Missouri, of which Sycamore is the commonest host. Other trees in the state on which it is found are American Elm, Swamp Tupelo (*Nyssa aquatica*), Tupelo (*Nyssa sylvatica* var. *caroliniana*), and River Birch. It has been found in other states on various other kinds of trees.

804 • *Aristolochia Serpentaria* var. *Serpentaria* (Virginia Snakeroot)

804 □ *Aristolochia Serpentaria* var. *hastata*

805 *Aristolochia tomentosa* (Pipe-vine)

806 *Eriogonum longifolium* (Umbrella Plant)

1. *Aristolochia Serpentaria* L.

Virginia Snakeroot

Map 804

Flowers late May–July.

Occurs in rich or rocky lowland or upland woods and thickets, generally on somewhat dry or well-drained slopes and ravines.

Two variations are represented in Missouri material:

Common type with ovate or ovate-oblong leaf-blades 2–9 cm. broad . . . 1a. *A. SERPENTARIA*
var. *SERPENTARIA*

Rare type with narrowly triangular to lanceolate leaf-blades 0.5–2.5 cm. broad . 1b. *A. SERPENTARIA*
var. *HASTATA*

1a. *Aristolochia Serpentaria* var. *Serpentaria*

Map 804

Common throughout southern and central Missouri, especially in the Ozark region, north to Marion, Shelby, Schuyler, Linn, Saline, and Jackson counties.

Ranges from Florida to Texas, north to Connecticut, New York, Ohio, Indiana, Illinois, Missouri, and Kansas.

1b. *Aristolochia Serpentaria* var. *hastata* (Nutt.)

Duchartre

Map 804

Known only from Dunklin and Dent counties in the southeastern one-quarter of the state.

Ranges from Florida to Texas, north to Virginia and Missouri.

Virginia Snakeroot usually occurs as scattered individual plants within an area. At one time the fragrant rootstocks, which resemble the odor of turpentine or menthol, were more frequently dug and used in medicine as a bitter tonic.

2. *Aristolochia tomentosa* Sims Pipe-vine

Map 805

Also known as Dutchman's Pipe

Flowers May–June.

Occurs in low alluvial woodland along streams, often along the stream banks, rarely in open ground. Rather frequent over most of the Ozark section in southern and central Missouri, north to Lincoln, Gasconade, Osage, Cole, Moniteau, Saline, St. Clair, and Bates counties; not recorded from some of the eastern and western Ozark counties.

Ranges from Florida to Texas, north to North Carolina, Indiana, Illinois, Missouri, and Kansas.

An unusual habitat for this species occurred in Scott County (sandy prairie along north side of road H, T27N, R14E, sect. 27, 3 mi. south of Blodgett, June 6, 1957, *Steyermark 85108*), where the plant trailed along the ground in an open sandy prairie. At first, it was believed to be referable to a different species, but was not found to be distinguishable from *A. tomentosa*.

The prominently 6-ridged capsule contains numerous flat seeds arranged in tiers somewhat resembling those of *Yucca* plants.

A related species, *A. durior* Hill, native to the eastern United States, and differing from *A. tomentosa* by the nearly glabrous stems, leaves, and flowers, is cultivated, but has not been recorded from Missouri as definitely naturalized. A specimen of this species at one time examined in the former herbarium of the Hannibal-La Grange College indicated 'Marion Co.' on the label, and was collected without doubt from a cultivated plant for the college collection.

Order **POLYONALES**Fam. **POLYGONACEAE** (Buckwheat Family)

- a. Vine, woody at least in lower part of stem, the stem tough and bearing tendrils at tips of branches; the mature sepals are joined to the flower- or fruit-stalk (pedicel) by a wing-like growth . . . 6. **BRUNNICHIA**
- a. No tendrils present on the plants, which are either erect or sprawling herbs or soft-stemmed, vining or sprawling plants, or, if woody on the stems, then the leaves are very narrow and hair-like; the mature sepals not joined to the flower- or fruit-stalk (pedicel) by any wing b
- b. Lower surface of leaves covered with a dense white felt mat of closely crowded hairs; base of plant, stem, and outside of flowers covered with a dense white hairiness; leaves without stipules 1. **ERIOGONUM**
- b. Without the above characters; lower surface of leaves not covered with a white mat of hairs; stem, and outside of flowers not covered with any dense white hairiness; leaves with stipules in the form of sheaths (ochreae) c
- c. Leaves very narrow, almost hair-like or needle-like; plants with tough woody branches. 5. **POLYGONELLA**
- c. Leaves not almost hair-like nor needle-like, or if nearly so, then no part of plant is woody. . . . d
- d. Sepals 6; the inner 3 sepals longer and enlarged in fruit; usually a cluster of leaves present at base of plant 2. **RUMEX**
- d. Sepals usually 5 or 4, but, if 6, then the flowers not occurring in many-flowered inflorescences; the sepals nearly equal in length in fruit or the inner sepals smaller; usually no cluster of leaves present at base of plant. e
- e. Flowers at the top of the stem in a broad corymb-like inflorescence broader than long or as broad as long, white, fragrant; leaves triangular-heart shaped; mature achene 3-sided, longer than and protruding from the soon withering calyx 4. **FAGOPYRUM**
- e. Flowers either in short clusters in the axils of the leaves or in longer than broad, loose or dense spikes, racemes, or panicles, white, pink, rose, or greenish; leaves narrow and linear to heart-shaped or arrow-shaped; mature achene 2-sided or 3-sided, enclosed within the surrounding calyx, or, if longer than and protruding from the persisting calyx, then the leaves narrow or the flowers in small clusters in the axils of the leaves . 3. **POLYGONUM**

1. **Eriogonum** Michx. Umbrella Plant**Eriogonum longifolium** Nutt.

Map 806

Flowers July–October.

Occurs on limestone glades and exposed edges of limestone bluffs bordering streams in southern Missouri, where known only from Oregon (1890, *Blankinship*), Ozark (west-facing bald knob along North Fork of White River, T21N, R12W, sect. 2, between Pumphrey Ford and White Ferry, 1½ mi. south of Udall, September 4, 1955, *Steyermark* 79628), and Taney (limestone glade on top of southwest-facing limestone bluffs along White River, T21N, R19W, sect. 7, 2 mi. south of Groom, 4–5 mi. south of Cedar Creek, April 30, 1938, *Steyermark* 5564, with sterile basal rosettes) counties.

Ranges from Missouri and Kansas to Oklahoma and Texas.

This is one of the rarest plants in Missouri, originally collected in 1890 in Oregon County by J. W.

Blankinship without any locality being indicated by him. Basal rosettes of the plant were found by the present author in 1938 in Ozark and Taney counties and transplanted to his wildflower garden. Not until 1955 did he find flowering plants at the Ozark County station. The flowers, which are yellow-green, are in clusters subtended by a gray-white hairy cup-shaped involucre. The inflorescence is loosely corymbosely branched at the summit of the single gray-white hairy tall stem which varies from 1.5–1.65 meters (5–5½ feet) tall, and has on it only 3 or 4 scattered leaves. The plant forms a basal rosette of long, narrow leaves which are dull olive-green on the upper side and have a dense, velvety, gray-white hairiness below. This rosette persists over winter. I have had the original Missouri plant in my botanical preserve since 1938 and it produced flowers for the first time during August and September of 1958.

Plate no. 142. 1. *Aristolochia tomentosa*, $\times \frac{2}{7}$. 2. *Eriogonum longifolium*; a. Inflorescence, $\times \frac{2}{7}$; b. Basal leaf, $\times \frac{2}{7}$; c. Single flower, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 3. *Rumex altissimus*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{2}{7}$. 4. *Rumex acetosella*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 5. *Rumex hastatulus*, $\times \frac{2}{7}$. 6. *Rumex mexicanus*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 7. *Rumex verticillatus*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{2}{7}$.

PLATE NO. 142

2. *Rumex* L. Dock, Sorrel

The flowers of this genus are wind-pollinated and some of the species are known to cause hay fever.

The seeds of some species were used by some of the American Indian tribes for making into a meal for a breadstuff.

- a. At least the lowest leaves arrowhead-shaped (hastate or sagittate) with basal lobes; leaves very sour to the taste; plants dioecious (male and female flowers on different plants) *b*
- b. Female sepals not enlarged in fruit; achene protruding from the female sepals; perennial plant with slender horizontal creeping rootstocks 1. *R. ACETOSELLA*
- b. Female sepals enlarged and prominently veined in fruit; achene shorter than and enclosed by mature female sepals; annual plants with a more or less vertical tap root 2. *R. HASTATUS*
- a. Leaves without basal lobes at base, either narrowed, rounded, more or less straight-sided, or heart-shaped at base; leaves not or scarcely sour to the taste; plants with most of flowers perfect or at least with both sexes on the same plant *c*
- c. Fruiting sepals (valves) with conspicuous long bristles, or spiny, coarse, or sharp teeth *d*
- d. Plants glabrous (without hairs) 9. *R. STENOPHYLLUS*
- d. Plants with minute hairs either on leaf-stalk, lower surface of at least the lower leaves, or on stem *e*
- e. Lower leaf-blades lanceolate, mostly less than 2 cm. broad, often tapering or narrowed at the base (also rounded, truncate, or heart-shaped); bristles of fruiting sepals (valves) $1\frac{1}{2}$ –2 times as long as width of mature sepal; low annual plants with hollow stems; plants of Missouri and Mississippi river muddy banks, mud flats, and sand bars 13. *R. MARITIMUS*
var. *FUEGINUS*
- e. Lower leaf-blades broadly oblong to broadly ovate, truncate (as if cut horizontally) or mostly heart-shaped at the base; teeth of fruiting sepals (valves) less than width of mature sepal; tall perennial plants with firm stems; plants of fields, roadsides, waste ground, about dwellings throughout Missouri *f*
- f. 3 grain-like tubercles (enlarged outgrowths) present, 1 appearing from center of each fruiting sepal (valve); lower leaf-blades 1.5–6 cm. broad; inflorescence interrupted, all the clusters of flowers separated from one another by relatively wide space intervals; flower or fruiting pedicels (stalks) shorter or at most as long as the flowering or fruiting sepals; rarely collected, known only from St. Louis County 11. *R. PULCHER*
- f. Only 1 well-developed grain-like tubercle (enlarged outgrowth) appearing from center of one of the fruiting sepals (valves); lower leaf-blades 5–15 cm. broad; upper clusters of flowers close together, not conspicuously separated from one another; flower or fruiting pedicels (stalks) much longer than the sepals; common throughout Missouri 12. *R. OBTUSIFOLIUS*
- c. Fruiting sepals (valves) either with smooth, wavy, or slightly bluntly toothed margins *g*
- g. Only 1 developed grain-like tubercle (enlarged outgrowth) present, appearing from center of one of the fruiting sepals (valves) or sometimes not even 1 developed *h*
- h. Larger lower leaf-blades 10–18 cm. wide; grain-like tubercle much less than $\frac{1}{2}$ the length of the fruiting sepal; fruiting sepals (valves) 6–9 mm. long, 8–9 mm. broad 6. *R. PATIENTIA*
- h. Larger leaf-blades less than 10 cm. wide; largest grain-like tubercle at least $\frac{1}{2}$ the length of the fruiting sepal; fruiting sepals (valves) 4–6 mm. long, 4–6 mm. broad *i*
- i. Leaves conspicuously wavy or wrinkled on margins; grain-like tubercle about $\frac{2}{3}$ as wide as long 8. *R. CRISPUS*
- i. Leaves flat and smooth, without wrinkled or wavy margins; grain-like tubercle $\frac{1}{2}$ as wide as long or narrower 5. *R. ALTISSIMUS*
- g. 3 well-developed grain-like tubercles (enlarged outgrowths) present, 1 appearing from center of each of the fruiting sepals (valves) *j*
- j. Side-veins of leaves spreading almost at right angles to midrib; pedicels (flower- or fruit-stalks) without a noticeable swollen joint 7. *R. ORBICULATUS*
- j. Side-veins of leaves ascending at acute angles to midrib; pedicels (flower- or fruit-stalks) with a noticeable swollen joint *k*
- k. Fruiting pedicels (stalks) straight, conspicuously turned downward, some of them 2–5 times as long as the fruiting sepals and 6–14 mm. long; plants usually growing at some stage in water, or in very wet places 3. *R. VERTICILLATUS*

- The sour leaves are a good thirst-quencher. The plant may be prepared for food in a number of ways, as a cooked vegetable, an ingredient in salads, as a seasoning in various dishes, as a soup, and as an acid beverage.

810 *Rumex mexicanus*811 *Rumex altissimus* (Pale Dock)812 *Rumex Patientia* (Patience Dock)2. ***Rumex hastatulus* Baldw.** Wild Sorrel

Map 808

Flowers April–May; fruits May–August.

Occurs in sandy open ground, along railroads, sandy or cherty glades, and prairies. Southeastern Missouri north along the Mississippi River counties to St. Louis County, and locally west in Newton County.

Ranges from Florida to Texas, north near the coast locally to Massachusetts, and inland north to southern Illinois, Missouri, and Kansas.

The enlarged fruiting sepals, much more conspicuous than in *R. Acetosella*, become straw-colored to pink when mature.

3. ***Rumex verticillatus* L.** Swamp Dock Map 809

Flowers April–June; fruits June–September.

Occurs in swamps, borders of sloughs, oxbow-lake meanders, and low wet woods. Throughout Missouri, but not recorded from many of the Ozark counties.

Ranges from Florida to Texas, north to Quebec, Ontario, Michigan, Wisconsin, and Minnesota.

This is the most aquatic of the common native species, the only other aquatic among the native species of Missouri being *R. orbiculatus*, which is very rare. *Rumex verticillatus* usually occurs in dense stands. It is common in bald cypress swamps of southeastern Missouri, and in around borders of natural ponds and sloughs elsewhere in the state. Its leaf-blades are smooth and flat, as in *R. mexicanus* and *R. altissimus*, and numerous sterile or basal leaves stand stiffly and prominently above the water.

This species, like many other docks, may be cooked as greens.

4. ***Rumex mexicanus* Meisn.**

Map 810

Rumex triangulivalvis (Danser) Rech. f. [Steyerm.]

Flowers April–May; fruits June–September.

Occurs along borders of swamps, low ground along streams, sloughs, and ponds. Scattered in northern and central Missouri, mostly in the western sectors of those areas, south to St. Louis, Saline, and Jackson counties.

Ranges from Newfoundland and Quebec to British Columbia, south to New York, Pennsylvania, Ohio, Indiana, Illinois, Missouri, Texas, New Mexico, and California; also in Mexico and Guatemala.

The young leafy shoots are eaten as a cooked vegetable.

5. ***Rumex altissimus* Wood** Pale Dock

Map 811

Flowers April–May; fruits May–August.

Occurs in alluvial ground along streams, sloughs, and ponds, often in flood plains, fields, thickets, waste ground in towns and cities, and along railroads. Throughout Missouri.

Ranges from Georgia to Texas, north to New York, Ohio, Michigan, Wisconsin, Minnesota, Nebraska, and Colorado; introduced in New England, New Jersey, and Virginia.

This is one of the commonest species of docks in Missouri. Alone, or in combination with Sour Dock (*R. crispus*), the young shoots in spring may be cooked as tasty greens.

6. ***Rumex Patientia* L.** Patience Dock Map 812*Rumex Patientia* var. *kurdicus* Boiss. [P & S, Steyerm.]

Flowers April–June; fruits June–July.

Occurs in waste ground and along railroads. Known only from St. Louis, Jackson, Clay, and Buchanan counties.

Native of Europe and Asia; introduced into the

Plate no. 143. 1. *Rumex Patientia*, $\times \frac{2}{7}$. 2. *Rumex orbiculatus*, $\times \frac{2}{7}$; a. Fruiting branch, $\times \frac{2}{7}$; b. Fruit, $\times 1^{\frac{5}{7}}$. 3. *Rumex crispus*, $\times \frac{2}{7}$. 4. *Rumex pulcher*, $\times \frac{2}{7}$; a. Fruit, $\times 1^{\frac{3}{7}}$; After Gleason, The New York Botanical Garden. 5. *Rumex conglomeratus*, $\times \frac{2}{7}$; a. Fruiting branch, $\times \frac{2}{7}$; b. Fruit, $\times 2^{\frac{6}{7}}$.

PLATE NO. 143

813 *Rumex orbiculatus* (Water Dock)814 • *Rumex crispus* (Sour Dock)
814 □ *Rumex crispus* X *Rumex obtusifolius*814A *Rumex stenophyllus*

United States, where naturalized from New England to Minnesota and Idaho, south to New York, Pennsylvania, Missouri, Oklahoma, and Utah.

The leaves are either flat or scarcely wavy on the margins, the main ones being rounded at the base. They are used as greens and are sometimes prepared into a thick soup.

7. *Rumex orbiculatus* Gray Water Dock

Map 813

Known also as Great Water Dock.

Rumex Brittanica of auth. [P & S, Steyermark.], not L. Flowers April–May; fruits June–September.

Occurs in moist alluvial ground along the Missouri River, where known only from St. Louis County (Natural Bridge Road, St. Louis, right-of-way of Mo. Pac. R.R., west of Knox Ave., August 14, 1955; *Muehlenbach* 725).

Ranges from Newfoundland and Quebec to North Dakota, south to New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Missouri, and Nebraska.

The leaves are flat and entire or finely wavy-toothed on the margins.

8. *Rumex crispus* L. Sour Dock

Map 814

Also known as Yellow Dock.

Rumex elongatus Guss. [P & S, Steyermark.]

Flowers April–May; fruits June–July.

Occurs in fields, garden soils, waste ground, along railroad tracks, and sometimes in low woods bordering streams, ponds, or sloughs. Throughout Missouri, and doubtless in every county.

Native of Europe; introduced into North America, where naturalized throughout the United States and Canada.

This is one of the species commonly used in the spring, either alone, or in combination with *R. altissimus*, wild lettuce (*Lactuca canadensis*), Sow Thistle

(*Sonchus* spp.), Dandelion (*Taraxacum* spp.), and Pokeweed (*Phytolacca americana*).

Handling the plant occasionally causes dermatitis in some persons. The root was used at one time for medicine and sold as Yellow Dock.

A rare variant, f. *unicallosus* Peterm., of *R. crispus* with only one well developed grain-like tubercle instead of 3 on the fruiting valve, has not been found in Missouri, but may be expected.

8a. *Rumex crispus* × *obtusifolius* Map 814

Hybrid plants between these species of *Rumex* have been found in St. Louis, Jefferson, Carroll, and Buchanan counties.

9. *Rumex stenophyllus* Ledeb. Map 814A

Rumex alluvius Gates & McGregor

Flowers May–June; fruits June–August.

Occurs in alluvial ground along the larger streams.

Known only from St. Charles (east and west of new highway 61 bridge, August 5, 1939, *Bauer* 519; Hamburg, August 6, 1939, *Bauer* 578), Clay (alluvial deposit, Missouri River valley, 2 mi. southeast of Missouri City, June 15, 1959, *McGregor* 14395), and Buchanan (along margin of Singleton Lake, T56N, R36W, sect. 25, 1½–2 mi. northwest of Halls, August 20, 1950, *Steyermark* 70087) counties.

Native of Eurasia; introduced in North America, where known from Manitoba, Wyoming, Colorado, North Dakota, South Dakota, Minnesota, Nebraska, Kansas, and Missouri.

This species resembles a hybrid between *R. crispus* and *R. obtusifolius*, but the fruiting sepals bear 3 grain-like tubercles, 1 on each valve. Besides the difference in number of tubercles present on the fruiting valves, *R. stenophyllus* differs from the true hybrid *R. crispus* × *obtusifolius* in the shape of the leaves and in being fertile instead of sterile, as in the hybrid.

815 *Rumex conglomeratus*816 *Rumex pulcher* (Fiddle Dock)817 *Rumex obtusifolius* (Bitter Dock)10. ***Rumex conglomeratus* Murr.** Map 815

Rumex sanguineus of some auth. [P & S], not L.

Flowers April–May; fruits June–July.

Known only from waste places in St. Louis County.

Native of Europe; introduced into the United States, where locally established from Virginia to South Carolina, Ohio, Indiana, Michigan, Illinois, Missouri, and the Pacific states.

The leaves are slightly wavy-crisped on the margins.

11. ***Rumex pulcher* L.** Fiddle Dock Map 816

Flowers April–July; fruits June–July.

Occurs along railroad tracks, known only from St. Louis County (St. Louis, along Mo. Pac. R.R., Plum Street, June 17, 1956, *Muehlenbach* 957, 1261; along Wabash R.R., north of Palm Street, June 28, 1958, *Muehlenbach* 1422).

Native of Europe; introduced in the United States, where naturalized from Florida to Texas and California, north locally to New York, Missouri, Oklahoma, and Oregon; also in Mexico.

The leaves are rather firm and thickish with a flat and entire or somewhat wavy margin.

12. ***Rumex obtusifolius* L.** Bitter Dock Map 817

Also called Blunt-leaved Dock, Broad-leaved Dock.

Flowers April–June; fruits June–September.

Occurs in fields, garden soils, waste ground, about dwellings, and rather damp soil of woodland and along streams. Throughout Missouri, but not recorded

from most of northern sections of western Missouri.

Native of Europe; introduced into North America, where naturalized from Newfoundland and Quebec to British Columbia, south to Florida, Texas, and Arizona.

The lowest leaves at the base are reddish-veined and have a rounded or blunt tip, while the upper ones are acutely pointed; the leaves are wavy-crisped on the margins.

13. ***Rumex maritimus* L. var. *fueginus* (Phil.)**

Dusen Golden Dock

Map 818

Flowers May–July; fruits July–October.

Occurs on wet alluvial mud banks and flats and sand bars of the Missouri and Mississippi rivers. Found from Clark County along the Mississippi River in northeastern Missouri south along that river to Perry County, and from Holt County along the Missouri River in northwestern Missouri south and east along that river to Jackson, Saline, Boone, Franklin, St. Charles, and St. Louis counties. Probably occurring in all the counties along those two rivers.

Ranges from Quebec to British Columbia, south along the coast to New Jersey, inland south to New York, Ontario, Illinois, Arkansas, New Mexico, Arizona, and California. Also in South America.

The leaves are quite thick and fleshy and rather crisped on the margins. The flower clusters usually extend nearly to the base of the plant and are frequently interrupted with leaves. At late maturity the fruiting masses turn a reddish-brown or copper color.

3. *Polygonum* L. Knotweed, Smartweed

- a. Stem armed with prickles *b*
 - b. Rare, known only from southeastern Missouri; lobes at base of leaves horizontally or wide-spreading, nearly at right angles to midrib; achenes 2-sided (lenticular) 20. *P. ARIFOLIUM*
 - b. Common, in many parts of Missouri; lobes at base of leaves pointing in the opposite direction from that of the tip of leaf; achenes 3-sided 19. *P. SAGITTATUM*
- a. Stems not armed with prickles *c*
 - c. Leaves broadly ovate, and most of them usually conspicuously heart-shaped or broadly rounded at base, rarely tapering or truncate at base *d*
 - d. Leaves truncate (as if cut horizontally across) or cuneate (wedge-shaped) at base; plants dioecious, the male and female flowers separated on different plants 24. *P. CUSPIDATUM*
 - d. Leaves usually more or less heart-shaped at base or with strongly curved or rounded base; plants with stamens and pistils on the same flower *e*
 - e. Plants growing in the water with floating leaves; leaves glabrous (without hairs) on both sides; stems glabrous *f*
 - f. Rare; inflorescence less than 4 cm. long, ellipsoid, narrowly ovoid, or thick cylindric; main stalk (peduncle) of inflorescence glabrous (without hairs); ocreolae (small sheathing stipules subtending flowers along axis of inflorescence) glabrous 7. *P. AMPHIBIUM*
var. *STIPULACEUM* f. *NATANS*
 - f. Common; inflorescence 4-18 cm. long, narrowly cylindric; main stalk (peduncle) of inflorescence hairy; ocreolae hairy 8. *P. COCCINEUM* var. *COCCINEUM* f. *NATANS*
 - e. Plants not growing in the water, without floating leaves; some part of leaves or stems or both with minute or conspicuous hairs *g*
 - g. Stems not twining, trailing, nor sprawling over the ground, 6-30 dm. tall *h*
 - h. Flowers greenish or greenish white, few and separated in a long narrow inflorescence; styles persistent and protruding in fruit as hooked or recurved beaks 21. *P. VIRGINIANUM*
 - h. Flowers rose to rose-red, many in a dense cylindric inflorescence; styles withering or falling in fruit, not hooked *i*
 - i. Stem usually 1.2-3 m. (4-10 feet) tall, with soft spreading hairs; lower leaf-surface soft hairy; inflorescence arching or drooping 13. *P. ORIENTALE*
 - i. Stem much shorter, mostly 0.6-0.9 m. (2-3 feet) tall, with hairs usually parallel to surface or lacking; lower leaf surface with hairs parallel to surface or lacking; inflorescence straight, erect or ascending 8. *P. COCCINEUM*
 - g. Stems twining, trailing, or sprawling over the ground, if erect only a few dm. tall *j*
 - j. Outer divisions of calyx keeled, but not winged, in fruit; achene dull, minutely roughened; fruiting stalks (pedicels) of flowers 3.5-4.5 mm. long 22. *P. CONVULVULUS*
 - j. Outer divisions of calyx strongly winged in fruit; achene shining, smooth; fruiting stalks (pedicels) of flowers as much as 4-10 mm. long *k*
 - k. Mature fruit, measured from the joint, 10-15 mm. long (the mature calyx 8-10 mm. long); wings of fruiting calyx 1.5-3 mm. broad at summit; achenes 3.5-6 mm. long, 2.5-4 mm. broad; common 23a. *P. SCANDENS* var. *SCANDENS*
 - k. Mature fruit, measured from the joint, 7-10 mm. long (the mature calyx 4-6 mm. long); wings of fruiting calyx 0.25-1 mm. broad; achene 2-3.5 mm. long, 1.5-2 mm. broad; rare 23b. *P. SCANDENS* var. *CRISTATUM*
 - c. Leaves either narrowly linear, lanceolate, or oblong, either tapering or narrowed to rounded at base, but not ovate with a heart-shaped or broadly rounded base *l*
 - l. All the flowers appearing at the base of the leaves in short clusters in their axils, sometimes only 1 or 2 in a cluster; leaves jointed at the base to the leaf-stalk (petiole) *m*
 - m. Stem with angled sides; leaves with 2 furrows, 1 on each side of midrib; margins of leaves with minute rough projections (difficult to see if leaf is folded in); plants of sandstone, chert, or granite glades and outcrops 6. *P. TENUE*
 - m. Stem with rounded or curved sides, terete (rounded in cross-section); leaves not furrowed; margins of leaves entire (smooth-edged) or very faintly irregular-edged with some projections; plants of prairies, fields, waste ground, along railroads, moist and alluvial ground, and around houses and farmplots *n*
 - n. Leaves oval, oblong, or elliptic, blunt or rounded at tip, $1\frac{1}{2}$ -3 times as long as broad, 3-25 mm. (mainly 10-25) broad *o*

- o. Leaves yellow-green; divisions of calyx yellow-green with yellow-green to white margins; mature flower-stalks (pedicels) protruding beyond and longer than the ocreae (sheathing stipules); achene mainly 3–3.5 mm. (sometimes 2.5) long 3. *P. ERECTUM*
- o. Leaves blue-green or silvery-green; divisions of calyx blue-green or green with rose- or purple-tinged margins or some of them with white margins; mature flower-stalks (pedicels) mostly included within and shorter than the ocreae (sheathing stipules); achene 2–2.5 mm. long. . . . *p*
- p. Fruiting calyx 3.5–4 mm. long, lobed to above the middle, strongly constricted below the narrowed tip; margins of inner divisions of calyx white; achene dull yellow-brown or olive; 3 outer divisions of calyx hooded (cucullate) near tip, somewhat ridged in the center, noticeably longer than the inner two divisions 4. *P. ACHOREUM*
- p. Fruiting calyx 2–3 mm. long, lobed to below the middle, not constricted below any narrowed tip; margins of calyx divisions mainly rose, pink, or purple, sometimes white; achene dark brown; 3 outer divisions of calyx flat, not hooded nor with a ridge, usually equaling or shorter than the inner two divisions 5. *P. AVICULARE* var. *VEGETUM* and var. *LITTORALE*
- n. Leaves narrowly linear, oblong-linear, narrowly lanceolate or oblanceolate, acute or blunt at tip, mainly $3\frac{1}{2}$ –9 times as long as broad, mainly 1–5 mm. (up to 10) broad *q*
- q. Stems mainly sprawling, lying on the ground or loosely ascending, generally less than 1.5 dm. tall; 3 outer divisions of calyx flat, not hooded nor with a ridge, usually equaling or shorter than the inner two divisions; calyx divisions lobed to just below middle; common weed of waste ground, lawns, dooryard, farmplot, salt licks and borders of saline springs 5. *P. AVICULARE* var. *AVICULARE*
- q. Stems erect with usually strongly ascending branches, mainly 3–20 dm. (rarely 1.5–3) tall; 3 outer divisions of calyx hooded (cucullate) near tip, somewhat ridged in the center, noticeably longer than the inner two divisions; calyx divisions lobed nearly to the base; plants of prairies and open ground. *r*
- r. Leaves yellow-green; divisions of calyx yellow-green with yellow margins; mature calyx divisions 3–4 mm. long; achene 2.2–6.5 mm. long; flower-stalks (pedicels) usually longer than the calyx, the flowers usually protruding beyond the ocreae (sheathing stipules) 2. *P. RAMOSISSIMUM*
- r. Leaves bluish green; divisions of calyx green with white or pink margins; mature calyx divisions 1.3–1.8 mm. long; achene 2 mm. long; flower-stalks (pedicels) shorter than the calyx, the flowers scarcely or not protruding beyond the ocreae (sheathing stipules) 1. *P. PROLIFICUM*
- l. Flowers several to many in dense or loose elongated inflorescences arising at the ends of the stems and branches; leaves not jointed to the leaf-stalk (petiole) *s*
- s. Sheathing stipules (ocreae) surrounding stem lacking a fringe of bristles at the top *t*
- t. Main flower-stalk (peduncle) and axis of inflorescence with hairs lying along and parallel to surface; perennial plants with creeping rhizomes and stolons; the sheathing stipules (ocreae) not prolonged on one side into an ovate extension, scarcely or not oblique (unequal-sided), shaped like a funnel or ice cream cone 9. *P. DENSIFLORUM*
- t. Main flower-stalk (peduncle) and axis of inflorescence either completely glabrous (without hairs) or with stalked or sessile glands; annuals without creeping rhizomes and stolons; the sheathing stipules (ocreae) prolonged on one side into an ovate extension, noticeably oblique (lop-sided) *u*
- u. Main flower-stalk (peduncle) and axis of inflorescence either completely glabrous or with sessile (without stalks) glands; inflorescences mostly arching or drooping at tip, 3–9 mm. thick; achenes 1.8–2.2 mm. long, 1.6–2 mm. broad; mature calyx constricted toward tip to form a beak of sepals over the achene 12. *P. LAPATHIFOLIUM*
- u. Main flower-stalk (peduncle) and axis of inflorescence with stalked glands (or completely glabrous in *P. pennsylvanicum* var. *eglandulosum*, a rarely collected variety); inflorescence erect or ascending, straight, 10–15 mm. thick; achenes 2.5–3.5 mm. long, 2.2–3.5 mm. broad; mature calyx not constricted toward tip to form a beak of sepals over the achene *v*
- v. Common type encountered with the flowers uniform, the styles and stamens mainly included within the calyx; one or both faces of the achene depressed or sunken in the center 11. *P. PENNSYLVANICUM*
- v. Rare type encountered with two types of flowers, some plants with styles long protruding from calyx and stamens included, other plants with styles included and stamens long protruding from calyx; achenes with both faces convex (curved outward with highest part in center) 10. *P. BICORNE*

818 *Rumex maritimus* var. *fueginus* (Golden Dock)819 *Polygonum prolificum*820 *Polygonum ramosissimum* f. *ramosissimum* (Bushy Knotweed)

- s. Sheathing stipule (ocrea) surrounding stem provided with a fringe of bristles at the top. w
 w. Calyx divisions with pale or dark dots x
 x. Achenes dull; calyx greenish or with purple tips; internodes 2-4 cm. long; inflorescence drooping or nodding at tip 14. *P. HYDROPIPER* and varieties
 x. Achenes shining; calyx white; internodes 3-8 cm. long; inflorescence slightly or not at all drooping 16. *P. PUNCTATUM* and varieties
 w. Calyx divisions lacking dots y
 y. Ocreolae (stipules at base of flower clusters along axis of inflorescence) with or without short hairs at the summit margins, the hairs when present at most 1 mm. long and shorter than the flowers; most of the achenes 2-sided (sometimes 3-sided); inflorescence dense, 7-12 mm. thick; mature sepals with prominent reticulation (network) at the base 16. *P. PERSICARIA*
 y. Ocreolae with some of the hairs at the summit margins 2-3.5 mm. long; achenes 3-sided; inflorescence with looser, less crowded flowers, mostly less than 7 mm. thick; mature sepals lacking any reticulation at their base z
 z. Commonly encountered throughout the state; native plants of swamps, streams, sloughs, ponds, and wet soils, often growing in the water; achenes 2-3 mm. long; the longer flowering or fruiting spikes mainly 3-8 cm. (sometimes 2) long; perennial plants with firm elongated rootstocks, often with basal offshoots in autumn; inflorescence pink, white, greenish-white, dull purple, or pale rose 18. *P. HYDROPIPEROIDES* and varieties
 z. Rarely encountered, known only from St. Louis County; introduced plants of waste ground, lawns, and streets; achenes 2-2.4 mm. long; the longer flowering or fruiting spikes 1-4 cm. long; annual plants with fibrous roots lacking elongated rootstocks or basal offshoots in autumn; inflorescence deep rose to rose-purplish 15. *P. CESPITOSUM* var. *LONGISETUM*

1. ***Polygonum prolificum*** (Small) Robins.

Map 819

Flowers July-November.

Occurs in open places in flood plain or alluvial soils near streams. Known only from Clay and Jackson counties in west-central Missouri.

Ranges from Maine to Virginia, and inland from Minnesota to Saskatchewan and Washington, south to Arkansas, Oklahoma, and New Mexico.

2. ***Polygonum ramosissimum*** Michx. f. ***ramosissimum*** Bushy Knotweed Map 820

Polygonum ramosissimum Michx. [G, P & S, Steyerm.]
Polygonum exsertum Small [G, P & S]

Polygonum triangulum Bicknell [P & S]

Flowers July-October.

Occurs in upland and low river bottom prairies, and in moist alluvial and open ground. Northern, central, and western Missouri, south to St. Louis, Cole, and Taney counties, locally in the southeastern lowland section in Pemiscot and Dunklin counties; absent from all the Ozark section except where found in the White River counties.

This species shows great variation in the length and shape of the fruit and in the extent of its protrusion from the calyx. This varies with the season of the year and on the same plant. As noted by Gleason (*New Ill. Fl.* vol. 2: 74. 1952), a broadly

Plate no. 144. 1. *Rumex obtusifolius*, $\times \frac{2}{7}$; a. Fruiting branch, $\times \frac{2}{7}$; b. Fruit, $\times \frac{2^2}{7}$. 2. *Rumex maritimus* var. *fueginus*, $\times \frac{2}{7}$. 3. *Polygonum ramosissimum*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{3^1}{7}$. 4. *Polygonum erectum*, $\times \frac{2}{7}$. 5. *Polygonum aviculare* var. *aviculare*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 6. *Polygonum achoreum*, $\times \frac{2}{7}$.

PLATE NO. 144

821 *Polygonum erectum*822 *Polygonum achoreum*

823 • *Polygonum aviculare* var. *aviculare* (Knotweed)
 823 □ *Polygonum aviculare* var. *vegetum*
 823 x *Polygonum aviculare* var. *littorale*

ovoid type of achene, scarcely broader than long and included in the calyx, may occur earlier in the season and at the older flowering nodes. An extreme form of this type of fruit, described as *P. triangulum* Bicknell from Atherton, Jackson County, Missouri, grades into typical *P. ramosissimum*. On the other hand, the narrowly ovoid to lanceolate type of achene, conspicuously protruding beyond the length of the calyx, is encountered later in the season or at the upper flowering nodes, and this longer type of achene, represented by *P. exsertum* Small, is 4–6.5 mm. long, whereas the smaller, broader, and included type of achene is 2.2–3.5. Both types of achenes are found on the same plant and at the same time, as noted by Gleason, and study of Missouri material is in full agreement with his conclusions. Fernald (eighth ed. *Gray's Manual*, p. 578) noted that the achenes of *P. ramosissimum* were both included and exserted, with the latter up to 4 mm. long.

Another form of *P. ramosissimum*, f. *atlanticum* Robins., with pink-margined calyx divisions, has not been recorded from Missouri.

3. ***Polygonum erectum* L.** Map 821
 Flowers late May–October.
 Occurs in low damp woodland, alluvial banks of

streams and ponds, and in roadside thickets. Throughout Missouri, but represented by few collections from northern Missouri.

Ranges from Quebec and Vermont to Wisconsin and Iowa, south to Georgia, Tennessee, Missouri, and Kansas; also in the Pacific states.

This simulates *P. ramosissimum* in the yellow-green color of leaves and calyx, but has broader and elliptical leaves.

As noted by Gleason (*New Ill. Fl.* vol. 2: 75, 1952), the achenes may be either shining, included, and 2.5 mm. long, or dull, protruding, and 3–3.5 mm. long.

4. ***Polygonum achoreum* Blake** Map 822
 Flowers mid-May–September.

Known only from waste ground in Jackson County, west-central Missouri (introduced, Sheffield, July 19, 1906, *Bush 4060* in Gray Herbarium).

Ranges from Newfoundland to Alaska, south to New York, Ontario, Michigan, Wisconsin, Missouri, South Dakota, Montana, and Colorado.

The plant resembles *P. erectum* in habit, but is more compact and the leaves and calyx are bluish-green. The ocreae are persistent and not torn into narrow fibrous shreds, as are those of *P. aviculare* and *P. erectum*.

Section **Avicularia** Knotweed

5. ***Polygonum aviculare* L.** Knotweed Map 823
 Also known by Knotgrass, Dooryard Weed, Hogweed, and many other names.
 Flowers May–November.

This is a highly variable species, different in habit of growth, and in size, shape, and texture of leaves. The following variations occur in Missouri:

- a. Leaves 1.5–5 mm. broad, usually linear or

narrowly lanceolate and $3\frac{1}{2}$ –9 times as long as broad . . . 5a. *P. AVICULARE* var. *AVICULARE*

- a. Leaves 4–15 mm. broad, oblong-lanceolate or oblong to oval or spatulate, mostly $1\frac{1}{2}$ –3 times as long as broad. b

- b. Leaves rather thin, pale green, acute (pointed) at tip, slightly wavy on margins, not prominently veined; stems erect or ascending. 5b. *P. AVICULARE* var. *VEGETUM*

824 *Polygonum tenue*

825 *Polygonum amphibium* var. *stipulaceum* f. *fluitans*
(Water Smartweed)

826 • *Polygonum coccineum* var. *coccineum* f. *coccineum*
(Water Smartweed)
826 □ *Polygonum coccineum* var. *coccineum* f. *natans*
826 x *Polygonum coccineum* var. *pratensis*

b. Leaves rather thick and firm or subcoriaceous, bluish- or gray-green, blunt or rounded at tip, the side veins rather prominent; stems usually spreading along the ground . 5c. *P. AVICULARE* VAR. *LITTORALE*

5a. ***Polygonum aviculare* var. *aviculare***

Map 823

Polygonum aviculare var. *angustissimum* Meisn. [P & S, Steyerl.]

Polygonum neglectum Bess. [Deam]

Polygonum aviculare L. [G, BB, P & S, Steyerl.]

Occurs in waste ground, along streets, lawns and gardens about dwellings, pastures, fields, and borders of salt licks and saline springs, often in clayey and hard-packed soils. Throughout Missouri, and doubtless in every county.

Ranges throughout the United States and Canada; also in Europe and Asia. Some authors consider this variation as a European native introduced in North America, others as representing both native North American and introduced Eurasian strains. It would appear that both types are present in Missouri. Certainly the fleshy-leaved, prostrate types found around salt licks and salt marshes of central Missouri in Saline, Howard, and Cooper counties show every indication of being part of the native flora of those distinctive areas.

5b. ***Polygonum aviculare* var. *vegetum*** Ledeb.

Map 823

Occurs in similar situations to those occupied by var. *aviculare*, except absent from the saline soil areas. Probably of wide occurrence throughout the state, but only rarely collected. Represented by a specimen from Boone Co. (north shore of Brushwood Lake, July 4, 1933, Drouet 637).

Ranges throughout North America.

5c. ***Polygonum aviculare* var. *littorale*** (Link)

W. D. J. Koch

Map 823

Polygonum buxiforme Small [P & S, Steyerl.]

Occurs in fields and waste ground, but is less common than var. *aviculare*. Scattered in Missouri. Representative collections are from St. Louis (Sept., 1845, Engelmann) and Jackson (Courtney, September 22, 1928, Bush 11647; September 5, 1913, Bush 7069) counties.

Ranges from Newfoundland to Alaska, south along the coast to South Carolina, and inland to New York, Tennessee, Arkansas, Oklahoma, Texas, and New Mexico.

The hard fruits of *Polygonum aviculare* var. *aviculare* and var. *littorale* have been used by various Indian tribes as an ingredient for their pinole meal or flour. These knotweeds are well-known as common weeds, but are frequently mistaken for grass by the uninformed. They persist during winter as densely leafy patches growing close to the ground among the grass, or are often present in poultry yards where they survive, better than grass, the constant tramping of chickens. The leaves are eaten by poultry and cattle. The house sparrow and other birds eat the achenes.

6. ***Polygonum tenue*** Michx.

Map 824

Flowers June–October.

Occurs in usually dry acid soils of sandstone, chert, or granitic glades, rocky prairies, and gravel bars along streams. Common throughout the Ozark and unglaciated prairie sections of southern and central Missouri, and locally in the northeastern half of the state in Clark, Lewis, Sullivan, Linn, and Chariton counties.

Ranges from Georgia, Alabama, Arkansas, Oklahoma, and Texas, north to Maine and Minnesota.

This rather spare-looking plant has slender erect stems and branches with erect narrowly lanceolate or

linear pointed leaves. It is frequently associated on dry acid soils in exposed situations with *Oenothera linnifolia*, *Hypericum gentianoides*, *Bulbostylis capillaris*, and *Crotonopsis elliptica*.

7. **Polygonum amphibium** L. var. **stipulaceum** (Colem.) Fern. f. **fluitans** (Eat.) Fern. Map 825
Water Smartweed

Polygonum natans (Michx.) Eat. [P & S]

Polygonum natans f. *natans* [BB]

Flowers June–September.

Growing in water, known only from Greene County, southwestern Missouri.

Ranges from Labrador to Alaska, south to New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Missouri, Nebraska, Colorado, and California.

8. **Polygonum coccineum** Muhl. Map 826

Water Smartweed

Also known as Shoestring Smartweed.

Flowers June–October.

Occurs usually in or bordering water of swamps, sloughs, oxbow lakes of river bottoms, streams, river bottom prairies or meadows, and along railroad tracks. Common throughout Missouri, although not recorded from many of the Ozark counties.

This is a highly variable species whose several modified forms appear to be responses to environmental changes correlated with a fluctuating water depth.

Missouri material may be divided into the following variations:

a. Growing in water with the floating leaves and branches glabrous (without hairs); upper leaves heart-shaped (cordate). 8b. *P. COCCINEUM* var. *COCCINEUM* f. *NATANS*

a. Growing on land or out of water with the upper leaves at most rounded at base; stems often hairy; leaves often hairy. b

b. Leaf-stalks attached near the base of the ocreae (sheath-like stipule); upper portions of stem and leaves glabrous or with finely appressed hairs; inflorescences up to 8 cm. long. 8a. *P. COCCINEUM* var. *COCCINEUM* f. *COCCINEUM*

b. Leaf-stalks usually attached near the middle of the ocreae (sheath-like stipule); upper portions of stems and leaves densely hairy; inflorescences up to 18 cm. long.

8c. *P. COCCINEUM* var. *PRATICOLA*

8a. **Polygonum coccineum** var. **coccineum** f.

coccineum

Map 826

Polygonum coccineum Muhl. [G, BB, P & S]

This variety appears to be the commonest in the state, where widely distributed, and probably in every county.

Ranges from Quebec to Washington, south to North Carolina, Kentucky, Arkansas, Oklahoma, Texas, and California.

8b. **Polygonum coccineum** var. **coccineum** f.

natans (Wieg.) Stanf.

Map 826

Polygonum coccineum f. *natans* (Wieg.) Stanf. [G]

Known only from Scott County, southeastern Missouri (swamp along road H, T28N, R14E, sect. 29, 3½ mi. north of Blodgett, June 6, 1957, *Steyermark 85128*). At this locality the stems were submerged in 2 feet of water and the leaves were floating. Plants were growing with *Scirpus heterochaetus*, *Eleocharis Smallii*, *Juncus acuminatus*, *Carex alata*, *Ranunculus sceleratus*, *Sparganium eurycarpum*, and *Sium suave*.

Occurs throughout the range of var. *coccineum*.

8c. **Polygonum coccineum** var. **pratincola**

(Greene) Stanford

Map 826

This is less common than typical var. *coccinea*, but is probably throughout the same area.

Ranges from Indiana to North Dakota, south to Arkansas, Oklahoma, Texas, and Mexico.

Polygonum coccineum and varieties, which some botanists prefer to treat as a single variable species, generally occupies large stands where it occurs, and frequently produces leafy stems only. Also in the drouth years few flowering spikes are found. These are of a deep rose-red color. The creeping black rootstocks, somewhat resembling black shoelaces, give the plant its common name in some localities. The achenes are eaten by various species of wildfowl.

9. **Polygonum densiflorum** Meisn.

Map 827

Polygonum portoricense Bertero

Flowers August–October.

Occurs in low wet woodland and swampy ground in southeastern Missouri, where known only from Scott (swamps, August 31, 1894, *Eggert*), Dunklin (Kennett, September 18, 1893, *Bush*; E. Bertig, St. Francis River, September 28, 1897, *Trelease 776*), and Carter counties.

Ranges from South and Central America, the West

Plate no. 145. 1. *Polygonum densiflorum*, × 2/7. 2. *Polygonum aviculare* var. *littorale*, × 2/7. 3. *Polygonum tenue*, × 2/7. 4. *Polygonum coccineum*, × 2/7. 5. *Polygonum bicornis*, × 2. 6. *Polygonum pensylvanicum*, × 2/7. 7. *Polygonum lapathifolium*, × 2/7. 8. *Polygonum Persicaria*, × 2/7. 9. *Polygonum Hydropiper*, × 2/7.

Indies, and Florida to Texas, north to New Jersey and Missouri.

10. ***Polygonum bicornes* Raf.** Map 828
Polygonum longistylum Small [G, BB, P & S]
Flowers July–October.

Occurs in swampy or low wet ground near streams, and along railroads. Rare, known only in southern and central Missouri, from St. Louis (along Mo. Pac. R.R., August 21, 1954, *Muehlenbach* 359), Dunklin (September 14, 1893, *Bush* 117A), Clay, Jackson (swamps, Atherton, August 1, 1902, *Mackenzie* 79; September 7, 1895, *Bush* 515), and Jasper counties.

Ranges from Louisiana to New Mexico, north to Illinois, Missouri, and Kansas.

Dr. Shinnars (Rh. 59: 265–67. 1957) has recently produced evidence to show that the earlier and correct name for this species is *P. bicornes*. The flowers are pale rose to pink, and the plant as a whole resembles the next species, *P. pensylvanicum*.

11. ***Polygonum pensylvanicum* L.** Pinkweed Map 829

Flowers May–October.

Occurs in wet ground bordering swamps, sloughs, streams, oxbow lakes of flood plain and other ponds, gravel bars, waste ground, and along roadsides and railroads.

Missouri material is represented by the following variations:

- a. Lower surface of leaves with hairs lying along the surface 11a. *P. PENSYLVANICUM* var. *PENSYLVANICUM* f. *PENSYLVANICUM*
- a. Lower surface of leaves glabrous or soon becoming glabrous. b
- b. Main flower-stalk (peduncle) and axis com-

pletely glabrous (without hairs)

11d. *P. PENSYLVANICUM* var. *EGLANDULOSUM*

b. Main flower-stalk (peduncle) and axis with stalked glands c

c. Flowers rose or pink . 11b. *P. PENSYLVANICUM* var. *LAEVIGATUM* f. *LAEVIGATUM*

c. Flowers white. . 11c. *P. PENSYLVANICUM* var. *ALBINEUM*

11a. ***Polygonum pensylvanicum* var. *pensylvanicum*** Map 829
Polygonum pensylvanicum L. [G, P & S, Steyerm.]

This is the commoner variety in Missouri, and occurs throughout the state, doubtless in every county.

Ranges from Nova Scotia to Ontario and Minnesota, south to Florida and Texas.

11b. ***Polygonum pensylvanicum* var. *laevigatum*** Fern. f. *laevigatum* Map 829
Polygonum pensylvanicum var. *laevigatum* [G, BB, P & S, Steyerm.]

This variety is recorded from less counties than var. *pensylvanicum*, but doubtless occurs in most of them; it has not been recorded from most of the Ozark section nor the southeastern lowland area of the state.

Ranges from Quebec to Minnesota, South Dakota, and Colorado, south to Virginia, North Carolina, Tennessee, Missouri, and Oklahoma.

11c. ***Polygonum pensylvanicum* var. *laevigatum* f. *albineum*** Farw. Map 829

This white-flowered form is known from Knox (open swale bordering ditch along highway 6, 4.6 mi. east of Edina, September 19, 1955, *Steyermark* 79656) and Pike (barnyard, Washington University experimental farm, west of Clarksville, May 24, 1948, *Etter* 154) counties.

830 • *Polygonum lapathifolium* var. *lapathifolium*
830 X *Polygonum pensylvanicum*

831 *Polygonum orientale* (Prince's Feather)

832 *Polygonum Hydropiper* (Water Pepper)

The achenes of *P. pensylvanicum* are a source of food for wildfowl and upland game birds, and the plant itself is browsed by deer and muskrat. In areas which have become recently impounded by high dams, this species, along with other members of the *Persicaria* group, take over and dominate newly available muddy shores. The fragrant flowers are much visited by bees.

11d. ***Polygonum pensylvanicum* var. *eglandulosum*** J. C. Myers Map 829

Known only from Greene County, southwestern Missouri (in mud along banks of a small stream near the east end of Fellows Lake, July 23, 1958, *Paul L. Redfearn, Jr.* 3796, in herb. Southwest Mo. State College).

Ranges in northern Ohio and Missouri, but probably much more common.

12. ***Polygonum lapathifolium* L. var. *lapathifolium*** Map 830

Polygonum lapathifolium L. [G, P & S]

Polygonum lapathifolium var. *nodosum* (Raf.) Weinm. [BB]

Flowers early June–November.

Occurs most frequently in low wet alluvial ground of mud flats and gravel bars along streams, borders of sloughs and ponds, in cultivated fields, waste ground, and along railroads. Throughout Missouri, but not recorded from some of the Ozark counties.

Ranges from Newfoundland to British Columbia, south throughout the United States and Mexico.

Other varieties have not been found in Missouri. This species and its varieties is one of the species of the genus most frequently eaten by various kinds of wildfowl. The flowers are either white, pink, or greenish, or combinations of these, the base of the calyx generally being greenish with white, straw-colored, or pinkish above. The slenderly cylindrical spikes are

usually arching or nodding at the tip, but are sometimes more erect.

12a. ***Polygonum lapathifolium* × *pensylvanicum*** Map 830

A plant intermediate between the two species and thought to represent a hybrid has been collected in Moniteau County.

13. ***Polygonum orientale* L.** Prince's Feather Map 831

Flowers June–October.

Occurs in waste and cultivated ground, where it has escaped from cultivation. Known from scattered counties over the state, but uncommonly found.

Native of Asia; introduced into North America where naturalized.

The large spikes of brightly rose-colored flowers droop from densely hairy peduncles, and are an attractive feature of this tall, stout herb.

14. ***Polygonum Hydropiper* L.** Water Pepper Map 832

Known also as Common Smartweed, Pepper Plant, and several other local names.

Polygonum Hydropiper var. *projectum* Stanf. [P & S]

Flowers late May–November.

Occurs in fields, pastures, moist ground bordering sloughs, streams, ponds, and wet often open logged woodland. Scattered throughout Missouri, and probably in every county.

Ranges from Quebec to British Columbia, south to Florida, Texas, and California.

The slender spike with greenish or white-bordered, mostly 4-parted flowers tapers to a slender arching tip. The glabrous annual stems are usually reddish or copper-red. The leaves are intensely burning to the taste, and cause a smarting sensation and irritation if the juice from the plant comes into contact with the

832A *Polygonum cespitosum* var. *longisetum*833 *Polygonum Persicaria* var. *Persicaria* (Lady's Thumb)834 • *Polygonum punctatum* var. *punctatum* (Water Smartweed)834 □ *Polygonum punctatum* var. *confertiflorum*834 x *Polygonum punctatum* var. *majus*

eyes or nostrils. Some cases in Europe have been reported of poisoning of stock traced to eating the plants. Rare cases of dermatitis from handling this species have been reported.

15. ***Polygonum cespitosum* Blume var. *longisetum*** (De Bruyn) Stewart Map 832 A
Polygonum caespitosum Blume [BB]
Polygonum longisetum De Bruyn
 Flowers June–October.

Occurs in waste ground, lawns, along streets and roadsides, where known only from St. Louis County (St. Louis, along sidewalk, 2300 Tower Grove Avenue, outside the grounds of Missouri Botanical Garden, October 17, 1959, *Steyermark 86179*; along grassy bor-

der of sidewalk, St. Louis, 2020 Tower Grove Avenue, October 17, 1959, *Isely & Pohl*).

Native of Asia; introduced and naturalized in the United States from Virginia and Kentucky to Missouri, north to Massachusetts and Illinois.

This species somewhat resembles *P. Persicaria*, but differs in the smaller, 3-sided achenes, mature sepals lacking the prominently reticulated bases of *P. Persicaria*, and generally more slender inflorescences with longer cilia (hairs) on the margins of the ocreolae. From *P. hydropiperoides* it differs in the smaller achenes, annual habit, differently shaped leaves, shorter inflorescences, and generally darker rose to rose-purple instead of pink, white, greenish-white or dull purplish sepals.

Section **Persicaria** Smartweed

16. ***Polygonum Persicaria* L. var. *Persicaria***
 Lady's Thumb Map 833
Polygonum Persicaria L. [G, BB, P & S]
 Flowers May–October.

Occurs in waste and cultivated ground, along railroads, wet meadows, and alluvial soils along streams. Scattered over the state, but recorded from fewer of the northern counties.

Native of Europe; introduced into North America, where naturalized throughout the United States and Canada.

This nearly glabrous annual usually has pink or dull rose-purplish and green, rarely white, flowers. Often the upper sides of the leaves are marked with a purplish or brownish patch near the middle. This species is reported to have similar properties of poisoning as those given for *P. Hydropiper*.

This is one of the species of *Polygonum* from which smartweed honey is derived. Other species are *P.*

pennsylvanicum, *P. longistylum*, and *P. hydropiperoides*. The achenes are frequently eaten by wildfowl and upland game birds.

17. ***Polygonum punctatum* Ell.**

Water Smartweed

Map 834

Flowers July–November.

Occurs in wet ground bordering streams, sloughs, and ponds, low damp places in woodland, and swampy places.

Missouri material may be divided into the following variations:

- a. Plants annual, the stems from a short tap-root, rooting at few or no nodes and scarcely prostrate at base; achenes usually both 3-sided and 2-sided on the same plant . . . 17b. *P. PUNCTATUM*
 var. *CONFERTIFLORUM*
 a. Plants perennial, the stems prostrate at base and rooting at the nodes; achenes all 3-sided . . . b

835 • *Polygonum hydropiperoides* var. *hydropiperoides* f. *hydropiperoides* (Wild Water Pepper)835 x *Polygonum hydropiperoides* var. *hydropiperoides* f. *strigosum*835 † *Polygonum hydropiperoides* var. *opelousanum*835 □ *Polygonum hydropiperoides* var. *setaceum*836 *Polygonum sagittatum* var. *sagittatum* f. *sagittatum* (Arrow-leaved Tear-thumb)837 *Polygonum arifolium* var. *pubescens* (Halberd-leaved Tear-thumb)

- b. Main leaves 1–2 cm. broad; fruiting calyx 3–3.5 mm. long; branches of the inflorescence from the axil of a blade-bearing leaf; stems much branched above the rooting base; common throughout Missouri

17a. *P. PUNCTATUM* var. *PUNCTATUM*

- b. Main leaves 2–4 cm. wide; fruiting calyx 3.5–5 mm. long; branches of the inflorescence from the axil of an ocrea not bearing a leafy blade; stems simple or nearly so above the rooting base; rare, known only from Dunklin Co., southeastern Mo. . . 17c. *P. PUNCTATUM* var. *MAJUS*

17a. *Polygonum punctatum* var. *punctatum*

Map 834

Polygonum punctatum Ell. [G, P & S]

This variety is common throughout Missouri and probably occurs in every county.

Ranges from the West Indies, Florida and Texas, north to New York, Iowa, and Kansas.

17b. *Polygonum punctatum* var. *confertiflorum*

(Meisn.) Fassett

Map 834

Polygonum punctatum var. *leptostachyum* (Meisn.)

Small and other auth. [G, BB, P & S], not *P. acre* var. *leptostachyum* Meisn., a tropical American variety north to Florida and Texas.

This variety is widespread in Missouri, but apparently somewhat less common than var. *punctatum*. It probably occurs in most counties of the state.

Ranges from Quebec to British Columbia, south to Virginia, Tennessee, Arkansas, Oklahoma, Colorado, Idaho, and Oregon.

17c. *Polygonum punctatum* var. *majus* (Meisn.)

Fassett

Map 834

Polygonum punctatum var. *robustius* Small

Polygonum robustius (Small) Fern. [G, BB, P & S]

Known only from southeastern Missouri in New Madrid (Pawpaw Junction, September 4, 1897, *Bush* 391) and Dunklin (Kennett, August 22, 1894, *Bush* 557) counties.

Ranges from South and Central America, and the West Indies, and from Florida to Nova Scotia, locally inland to Indiana and Missouri.

As Fassett has shown in his paper on *Polygonum punctatum* (Brittonia 6: 369–93. 1949), the occurrence of so many intermediate specimens makes it impossible to maintain *P. robustius* as a species distinct from *P. punctatum* and varieties, although in certain parts of their range, as in Nova Scotia, they appear more distinct with little or no intergradation.

Occasionally, the stems of *P. punctatum* and varieties are purple-red simulating those of *P. Hydropiper*. The spikes have less of a tendency to droop as much at the tip as those to *P. Hydropiper*.

The achenes of *P. punctatum* and varieties serve as desirable food for wildfowl and upland game birds, and the plant is browsed by deer and muskrat. The leaves possess a sharp burning quality similar to those of *P. Hydropiper*, and have the same type of poisoning and irritant effects as that species.

18. *Polygonum hydropiperoides* Michx.

Wild Water Pepper

Map 835

Flowers June–November.

Occurs in and bordering water of swamps, natural and made ponds, along streams and spring branches, and low wet woodland.

Missouri material may be divided into the following varieties:

- a. Hairs of the ocreae (sheath-like stipules) spreading (do not confuse with the hairs projecting from the margins at the summit) .

18d. *P. HYDROPIPEROIDES* var. *SETACEUM*

- a. Hairs of the ocreae (sheath-like stipules) erect and appressed (parallel to or lying along surface) *b*
- b. Mature achene slightly protruding from calyx, averaging 1.9 mm. long (1.5–2.5 mm.), 1.5–2 mm. wide (4/5 as wide); leaves narrowly lanceolate to nearly linear, 0.4–1.5 cm. broad 18c. *P. HYDROPIPEROIDES* var. *OPELOUSANUM*
- b. Mature achene included within the calyx, averaging 2.2 mm. long and 1.7–2 mm. wide (2/3 as wide); leaves narrowly to broadly lanceolate, 0.5–2.5 cm. broad *c*
- c. Leaves glabrous to minutely strigose (with hairs lying pressed to surface or paralleling surface) on one or both surfaces 18a. *P. HYDROPIPEROIDES* var. *HYDROPIPEROIDES* f. *HYDROPIPEROIDES*
- c. Leaves densely long-strigose 18b. *P. HYDROPIPEROIDES* var. *HYDROPIPEROIDES* f. *STRIGOSUM*

18a. ***Polygonum hydropiperoides* var. *hydropiperoides* f. *hydropiperoides*** Map 835

Polygonum hydropiperoides Michx. [G, P & S]

Polygonum hydropiperoides var. *Bushmanum* Stanford [G]

Polygonum hydropiperoides var. *euronotorum* Fern. [G]

Occurs throughout Missouri and is the commonest variation found in the state.

Ranges from Nova Scotia to British Columbia, south to Florida, Texas, and California.

18b. ***Polygonum hydropiperoides* var. *hydropiperoides* f. *strigosum***. (Small) Stanford

Map 835

Polygonum hydropiperoides f. *strigosum* (Small) Stanford [G, P & S]

Scattered in southern and central Missouri.

Ranges from Quebec to Pennsylvania and Missouri.

18c. ***Polygonum hydropiperoides* var. *opelousanum*** (Riddell) Stone Map 835

Polygonum opelousanum Riddell [G, P & S]

Occurs in southeastern Missouri northeast to Cape Girardeau and St. Francois counties, west to Oregon County, and reappears in southwestern Missouri from McDonald County north to Bates County.

Ranges from Florida to Texas and Mexico north on the coastal plain to Massachusetts and New York, inland north to Tennessee, Illinois, Missouri, and Oklahoma.

18d. ***Polygonum hydropiperoides* var. *setaceum*** (Baldw.) Gl. Map 835

Polygonum setaceum Baldw. [G, P & S]

Polygonum setaceum var. *interjectum* Fern. [G]

Polygonum setaceum var. *tonsum* Fern.

Polygonum hydropiperoides Michx. var. *hydropiperoides* [of Shinnery]

Occurs in southern and east-central Missouri, north to St. Louis, Phelps, Henry, and Jasper counties.

Ranges from Florida to Texas, north to Massachusetts, New York, Michigan, Missouri, and Oklahoma.

Gleason's interpretation (*New Ill. Fl.* vol. 2: 82, 1952) of this group has been followed in the present treatment and is believed to be the most general satisfactory alignment of the species available at the present time. The present author has collected and studied a large series of specimens of the *P. hydropiperoides* – *P. setaceum* – *P. opelousanum* alliance during the past twenty-five years, but in attempting to separate the plants according to the outline proposed by Fernald in the eighth edition of *Gray's Manual* (p. 576, pp. 586–87), I have found numerous intergradations and intermediates at all levels of comparison. In *P. hydropiperoides* it was not found possible to maintain var. *Bushmanum* apart from var. *hydropiperoides* on account of intergradation in length of cilia on the ocreae, and many plants with long cilia in Missouri possessed narrow leaves that would have fit the description for var. *euronotorum* Fern., supposedly a variety confined to Virginia and South Carolina. Similarly with *P. setaceum* no constancy could be found between the pubescence of the leaves and ocrea of the three variations indicated by Fernald. Moreover, habit and habitat characters given by Fernald, supposed to distinguish *P. opelousanum* and *P. setaceum*, were found inadequate and unreliable guides, and, as noted by Gleason, it is not possible to distinguish *P. opelousanum* from *P. hydropiperoides* except at maturity.

Continued maintenance of these three entities as distinct species, in the light of such intergradation and lack of definition, would only lead to further confusion. Until a completely new and badly needed revision of

Plate no. 146. 1. *Polygonum punctatum*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 2. *Polygonum hydropiperoides* var. *hydropiperoides*, $\times \frac{2}{7}$. 3. *Polygonum sagittatum*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 4. *Polygonum virginianum*, $\times \frac{2}{7}$; a. Fruit, $\times \frac{15}{7}$; Details from Small, The New York Botanical Garden. 5. *Fagopyrum sagittatum*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 6. *Polygonum arifolium* var. *pubescens*, $\times \frac{2}{7}$. 7. *Polygonum scandens* var. *scandens*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 8. *Polygonum Convolvulus* var. *Convolvulus*, $\times \frac{2}{7}$.

PLATE NO. 146

this alliance is forthcoming, Gleason's interpretation may well be taken as a guide to the future approach of study of these plants.

The flowers of *P. hydropteroides* var. *hydropteroides* are either pink or roseate, and rarely white, those of var. *setaceum* usually white, and of var. *opelousanum* greenish-white or green and purplish. *Polygonum hydropteroides* var. *hydropteroides* usually is found in dense stands, in shallow water. It also occurs in a purely vegetative state submerged in the cold water of springs and spring branches in the Ozark region. In such

situations, and in fast-running spring water, the submerged stems and leaves bend horizontally, paralleling the stream bed, with their olive-green leaves often flushed with purple and red shades waving in the current. Frequently these submerged leaves are bronze-purple on the lower surface and olive-green on the upper surface, or the leaves may be tinged copper or reddish in some plants, orange and green in others. Achenes of *P. hydropteroides* frequently are eaten by various kinds of wildfowl.

Section **Echinocaulon** Tear-thumb

19. **Polygonum sagittatum** L. var. **sagittatum** f. **sagittatum** Arrow-leaved Tear-thumb

Map 836

Polygonum sagittatum L. [G, BB, P & S]

Flowers June–October.

Occurs in swampy places around springs, spring branches, sloughs, and streams. Common over a large section of eastern, southern, and central Missouri, and locally northwest to Livingston County; not recorded from a number of Ozark counties.

Ranges from Florida to Texas, north to Newfoundland, Quebec, Ontario, and Saskatchewan.

A nearly smooth-stemmed variation, var. *gracilentum* Fern., occurs in Virginia, and a form of var. *sagittatum*, f. *chloranthum* Fern., with green flowers and reduced ciliation of leaves, occurs from Maine to New York.

20. **Polygonum arifolium** L. var. **pubescens** (Keller) Fern. Halberd-leaved Tear-thumb

Map 837

Polygonum arifolium of some auth. [P & S], not L.

Flowers July–October.

Occurs in wet sandy swales of spring branches.

Known only from Crowley Ridge in Stoddard County in southeastern Missouri (swampy sandy ground of spring branch at base of Crowley Ridge, T₂₅N, R₁₁E, northwest $\frac{1}{4}$ sect. 6, $3\frac{1}{2}$ mi. southeast of Bloomfield, August 20, 1954, *Steyermark* 76781; T₂₅N, R₁₀E, southeast $\frac{1}{4}$ sect. 11, 4–4 $\frac{1}{4}$ mi. south of Bloomfield, October 18, 1955, *Steyermark* 80440; without locality in Stoddard Co., *Bush*).

Ranges from New Brunswick to Ontario and Minnesota, south to New Jersey, Pennsylvania, Ohio, Indiana, and Missouri.

Typical *P. arifolium* var. *arifolium* has larger achenes 4–4.2 mm. instead of 3–3.5 mm. broad and 3–3.2 mm. instead of 2.2–2.6 mm. thick with a slight point, sometimes projecting from the center of the sides of the achene.

This rare *Polygonum* in Missouri is associated at one of its Stoddard County stations with such other relict eastern species as *Bartonia paniculata*, *Trisetum pensylvanicum*, and *Pyrus melanocarpa*, accompanied by such other rarities as *Habenaria ciliaris*, *Eupatorium fistulosum*, and *Ilex opaca*.

Section **Tovara** Virginia Knotweed

21. **Polygonum virginianum** L.

Virginia Knotweed

Map 838

Flowers July–October.

Occurs in rich woodland. Throughout Missouri.

Two variations occur in Missouri:

Leaves usually hairy on lower surface, hairy on upper surface; leaves thick and firm

21a. *P. VIRGINIANUM* var. *VIRGINIANUM*

Leaves glabrous (without hairs) or nearly so;

leaves thin and membranous 21b. *P. VIRGINIANUM* var. *GLABERRIMUM*

21a. **Polygonum virginianum** var. **virginianum**

Map 838

Polygonum virginianum L. [BB, P & S]

Tovara virginiana (L.) Raf. [G]

This is the common variation in the state and doubtless occurs in every county.

Ranges from Quebec and New Hampshire to Ontario and Minnesota, south to Florida and Texas.

21b. **Polygonum virginianum** var. **glaberrimum**

(Fern.) Steyererm.

Map 838

838 • *Polygonum virginianum* var. *virginianum* (Virginia Knotweed)
839 □ *Polygonum virginianum* var. *glaberrimum*

839 *Polygonum convolvulus* (Black Bindweed)

840 • *Polygonum scandens* var. *scandens* (False Buckwheat)
840 □ *Polygonum scandens* var. *cristatum*

Tovara virginiana var. *glaberrima* Fern. [G]

Known only from Pemiscot County in south-eastern Missouri (virgin woods on level ground on property of Son Rone, T20N, R12E, sect. 12, 3 mi. south-southwest of Portageville, July 29, 1956, *Steyermark* 82232).

Ranges from Virginia to Florida and Missouri.

22. ***Polygonum convolvulus* L. var. *convolvulus***
Black Bindweed Map 839
Flowers May–November.
Occurs along roadsides, railroads, in cultivated

fields and waste ground. Scattered throughout Missouri, and probably eventually to be found in most of the counties.

Native of Europe; introduced into North America, where naturalized over most of the United States and Canada.

Another variation, var. *subalatum* Lej. & Court., differs in the fruiting calyx 5–8 mm. instead of 4–5 mm. long, and with 3 developed winged keels.

Some primitive peoples are reported to use the achenes which are mashed into a meal or flour said to possess somewhat the qualities of buckwheat flour.

Section **Tiniaria** Climbing Buckwheat

23. ***Polygonum scandens* L.** False Buckwheat Map 840
Flowers July–November.
Occurs in moist thickets, alluvial woods and flood plain forest, about lakes and sloughs, streams, along rocky bluffs, and on dry wooded slopes.

is known in scattered sections of the state in Macon (*Steyermark* 77373), Miller, Crawford, Bollinger (*Steyermark* 77735), and Stoddard (*Steyermark* 76845) counties.

Ranges from Florida to Texas, north to Massachusetts, Vermont, New York, Indiana, Illinois, Minnesota, and Kansas.

- 23a. ***Polygonum scandens* var. *scandens*** Map 840
Polygonum scandens L. [G, P & S]
This is the common variation encountered.
Throughout Missouri, and doubtless in every county.
Ranges from Florida to Texas, north to Nova Scotia, Quebec, Ontario, and Manitoba.

Gleason's interpretation of the *Polygonum scandens* – *P. cristatum* alliance is followed in the present treatment, rather than Fernald's since the variations in the size of the achene, the length of the fruiting calyx, and the relative width of the wing appear to intergrade too freely to permit recognition of these entities as distinct species.

The achenes of *P. scandens* var. *scandens*, as with those of *P. convolvulus*, have been used in making meal.

- 23b. ***Polygonum scandens* var. *cristatum***
(Engelm. & Gray) Gl. Map 840
Polygonum cristatum Engelm. & Gray [G]
Polygonum scandens var. *dumetorum* (L.) Gl. [BB]
Polygonum dumetorum of some auth., not L.
This is the less common variation in Missouri, and

24. ***Polygonum cuspidatum* Sieb. & Zucc.**
Japanese Knotweed Map 841
Also known as Mexican Bamboo.
Flowers August–September.
Escaped into waste ground, fence rows, and along roadsides and railroads. Scattered in a few sections of

841 *Polygonum cuspidatum* (Japanese Knotweed)842 *Fagopyrum sagittatum* (Buckwheat)843 *Polygonella americana* (Jointweed)

the state, in Daviess, Jackson, Boone, St. Louis, and Cape Girardeau counties.

Native of Japan; introduced into North America, where naturalized from Newfoundland to Ontario

and Minnesota, south to Maryland and Missouri.

The young underground rootstocks and young leafy stems can be cooked as a palatable vegetable substitute for asparagus, or treated as a salad.

4. *Fagopyrum* Mill. Buckwheat

Fagopyrum sagittatum Gilib. Buckwheat

Map 842

Fagopyrum esculentum Moench. [BB, P & S, Steyerm.]

Flowers May–September.

Escaped into fields, pastures, cultivated and waste ground, along roadsides, and railroads. Rarely persisting and known as an occasional waif from a few scattered counties in the state.

Native of Asia; introduced into North America.

The well-known buckwheat flour is produced from the achenes of this plant. Some people are allergic to

buckwheat, developing a rash after eating dishes prepared from the flour. Some persons are also sensitive to the leaves, developing a dermatitis after contact. Stock of all kinds having an uncolored skin may be poisoned if they are directly exposed to the sun after eating buckwheat. The fragrant flowers are the source of buckwheat honey, the plants are often grown as a green manure to enrich the soil, and the discarded dried hulls or remains of the fruits are used as a summer mulch for roses and other flower beds.

5. *Polygonella* Michx. Jointweed

Polygonella americana (Fisch. & Mey.) Small

Jointweed

Map 843

Flowers July–October.

Occurs in dry sandy ground, mainly on Crowley Ridge in the southeastern lowland section of the state in Scott, Stoddard, and Dunklin counties, and locally in Iron County in the southeastern Ozarks.

Ranges from southeastern Missouri to Georgia and Texas.

This plant with its small, crowded, needlelike, gray-green leaves has the appearance of a small

spreading heather or juniper. The branches usually are low and spreading, mostly 3–9 dm. tall, and at their tips develop racemes of showy white to pink-tinted flowers, which continue to bloom through summer and fall. This plant does satisfactorily in a rock garden if provided with acid sand and good drainage. A plant has prospered at the author's botanical preserve since 1954. It can also be easily grown from seed and should make a desirable horticultural accessory.

Plate no. 147. 1. *Polygonella americana*; a. Flowering portion of plant, $\times \frac{2}{5}$; b. Leafy portion of plant, $\times \frac{2}{5}$; c. PLATE NO. 147

6. *Brunnichia* Banks***Brunnichia cirrhosa*** Gaertn. Ladies' Eardrops.

Map 844

Also known as Buckwheat Vine.

Flowers May–August; fruits August–October.

Occurs in swamps, low wet woods, and moist alluvial thickets in the lowland section of southeastern Missouri, north to Bollinger and Wayne counties and

west to Ripley County.

Ranges from Florida to Texas, north to South Carolina, Kentucky, Illinois, Missouri, and Oklahoma.

The common name is derived from the appearance of the long narrow winged fruit to ear decorations. This woody vine often climbs to the tops of tall trees in favorable situations. The flowers are greenish.

Order **CARYOPHYLLALES**Fam. **CHENOPODIACEAE** (Goosefoot Family)I. *Key based chiefly on vegetative characters*

- a. Leaves or flower-bracts ending in a more or less prickly or spiny stiff tip 9. *SALSOLA*
- a. Neither leaves nor flower-bracts ending in a prickly or spiny stiff tip *b*
- b. Star-shaped hairs (stellate pubescence) present on lower surface of leaves, on calyx of female flowers, or on some part of plant (do not confuse plants with scales or scurfy or mealy covering, which do not belong here) *c*
- c. Leaves narrowly linear with sides parallel or nearly so, sessile (without stalks) 7. *CORISPERMUM*
- c. Leaves lanceolate to elliptic-ovate, usually broader in the middle or below the middle, short- or long-stalked 5. *AXYRIS*
- b. Plants hairy or without hairs, but if hairy the hairs not star-shaped (scurfy, scaly, or mealy coverings, if present, belong here) *d*
- d. Main leaves either thread-like, narrowly linear, or narrowly lanceolate, with their sides parallel or nearly so, nearly of equal width throughout or slightly broader in the middle, or if broader and dilated at the base then many times (8–15) as long as broad; no teeth, lobes, or irregularities on margins of leaves *e*
- e. Hairs present on some part of plant 2. *KOCHIA*
- e. Hairs absent *f*
- f. No mealy, scaly, or scurfy covering on leaves, stems, or flowers *g*
- g. Leaves thick and fleshy, nearly terete (mostly rounded in cross-section) or flattened above, not nerved; calyx 5-parted; fruit surrounded or enclosed by the calyx 8. *SUAEDA*
- g. Leaves not fleshy, flattened with upper and lower sides, 1-nerved; calyx of 1 small sepal, or if rarely with 3 sepals, these minute and thin-transparent; fruit free from calyx and exposed and protruding above it 7. *CORISPERMUM*
- f. Mealy, scaly, or scurfy covering, this sometimes white or gray, on leaves, stems, or flowers *h*
- h. Upper part of stem and lower surface of leaves densely white- or gray-mealy 3. *CHENOPODIUM*
- h. Stem and leaves dark or dull green throughout 4. *ATRIplex PATULA* var. *LITTORALIS*
- d. Main leaves oblong, elliptical, broadly lanceolate, ovate to triangular, usually broader at the middle or in the lower half, mostly only $1\frac{1}{2}$ –5 times as long as broad, or if linear, thread-like, or narrow, at least some teeth or irregularities are present; teeth, lobes, or irregularities on margins of leaves *i*
- i. Plants aromatic, the stems and leaves or flowers with glandular hairs or sessile glands. 3. *CHENOPODIUM*
- i. Plants not aromatic, no part of plant with glandular hairs or glands (plants with mealy, scurfy, or scaly covering belong here) *j*
- j. Upper part of stem and young leaves with white cobwebby hairs 1. *CYCLOLOMA*
- j. No white cobwebby hairs on any part of stem or leaves *k*
- k. Sepal only 1 in each flower; stamen 1 6. *MONOLEPIS*

- k. Calyx 2-5-parted in all flowers or at least in the staminate flowers; stamens mostly 3-5 (rarely 1-2) *l*
- l. Stamens and pistils separated from each other on different flowers of the same plant (monoecious) or on different plants (dioecious); female flowers mostly without any calyx; fruit hidden in a pair of rounded, triangular, or baseball-diamond-shaped little bracts 4. *ATRIPLEX*
- l. Stamens and pistils in the same flowers, flowers all perfect; fruit surrounded by the calyx, without any bracts around it *m*
- m. Fruiting calyx with a continuous wing around it; plants frequently of open sandy places 1. *CYCLOLOMA*
- m. Fruiting calyx without any wing; plants more often found in mud, on loamy, clayey, or fertile organic soils in woodland, along bluffs, bottomland, waste ground, and about dwellings 3. *CHENOPODIUM*

II. Key based mainly on flower and fruit characters

- a. Calyx of usually only 1 sepal in each flower (if rarely 3 sepals, these minute and thin-transparent); fruit exposed, free, not surrounded or enclosed by bracts or by the calyx *b*
- b. Main leaves linear, with mostly parallel sides and of about equal width throughout; no leaves with any teeth or irregularities on margin, sessile (without a stalk); sepals 1-3, minute and thin-transparent; fruit usually with a thin or winged margin 7. *CORISPERMUM*
- b. Main leaves somewhat arrowhead-shaped, at least the upper ones broadest near the base, or if narrowed at the base and linear or not arrowhead-shaped, at least with 1 or more teeth or irregularities on margins; main leaves with at least 1 large tooth on each side, petioled (with a stalk); sepal 1; fruit without any wing 6. *MONOLEPIS*
- a. Calyx 2-5-parted in all flowers or at least in the staminate flowers; fruit either surrounded and enclosed by the calyx or hidden by 2 bracts *c*
- c. Stamens and pistils separated from each other on different flowers of the same plant (monoecious) or on different plants (dioecious); female flowers mostly without any calyx; fruit hidden in a pair of rounded, triangular, or baseball-diamond-shaped little bracts 4. *ATRIPLEX*
- c. Without the above combination of characters *d*
- d. Leaves with teeth, lobes, or irregularities on the margins; leaves ovate to triangular, oblong, elliptical, or broadly lanceolate, usually broader at the middle or in the lower half, mostly only $1\frac{1}{2}$ -5 times as long as broad *e*
- e. Fruiting calyx with a continuous wing around it; plants frequently of open sandy places 1. *CYCLOLOMA*
- e. Fruiting calyx without any wing; plants more often found in mud, on loamy, clayey, or fertile organic soils in woodland, bottomland, along bluffs, waste ground, and about dwellings 3. *CHENOPODIUM*
- d. Leaves without teeth, lobes, or irregularities on margins; leaves either thread-like, narrowly linear, or lanceolate, their sides parallel or nearly so, nearly of equal width throughout or slightly broader in the middle, many times (8-15) as long as broad, or, if elliptic-ovate then the flowers unisexual with male and female flowers separate *f*
- f. Fruiting calyx or fruit partly or wholly winged, the fruit either 2-winged at its summit or the fruiting calyx-lobes themselves developing wings or transverse keels *g*
- g. Fruit 2-winged at its summit, the calyx not winged; lower surface of leaves and calyx of female flowers with star-shaped hairs (stellate pubescent); stamens and pistils in separate flowers on the same plant (monoecious), the staminate flowers raised high above rest of inflorescence; fully grown female bracts and calyx conspicuous, white . 5. *AXYRIS*
- g. Fruit not winged, but each of the 5 calyx-lobes are winged or transversely keeled; hairs, when present, simple, not star-shaped; stamens and pistils in the same flower, perfect; calyx and bracts not white *h*
- h. Leaves and bracts with bristly or spiny tips 9. *SALSOLA*
- h. Leaves and bracts soft, lacking bristly or spiny tips 2. *KOCHIA*
- f. Fruiting calyx and fruit without any winged part 8. *SUAEDA*

Winged Pigweed***Cycloloma atriplicifolium*** (Spreng.) Coul.

Winged Pigweed

Map 845

Flowers June–October.

Occurs in sand flats along the Missouri and Mississippi rivers, sand bars along a few Ozark streams, sand ridges, sandy fields and sandy open ground, occasionally along railroads and sandy roadsides. Found along the counties bordering the Mississippi and Missouri rivers in eastern and central Missouri, and scattered elsewhere in southern Mis-

souri in Phelps, Dent, St. Francois, and Jasper counties; on sand of Crowley Ridge in southeastern Missouri in Scott, Stoddard, and Dunklin counties.

Ranges from Indiana to Manitoba, south to Illinois, Arkansas, Texas, Mexico, Arizona, and California, occasionally spread east to Quebec, New England, and New Jersey.

The plant is a characteristic sand-inhabiting species. Late in autumn the fruit and the rest of the plant may turn a reddish-purple.

2. *Kochia* Roth***Kochia scoparia*** (L.) Schrad. Summer Cypress,

Fire Bush

Map 846

Flowers July–October.

Missouri material is represented by the following variations:

- a. Leaves narrowly linear, thread-like, mostly 1–2 mm. broad, inconspicuously hairy; shape of plant ovoid or globular, branches close together; plant turning purplish-red or deep rose-red c. *K. scoparia* var. *culta*
- a. Leaves linear-lanceolate or oblanceolate, 3–8 mm. broad, more conspicuously hairy, the hairs up to 2 mm. long; shape of plant pyramidal, branches loosely spreading, not close together; plant remaining green b
- b. Stem downy, conspicuously densely hairy with sordid or brownish-white hairs; leaves and flowers conspicuously hairy; rare type
b. *K. scoparia* var. *pubescens*
- b. Stem sparsely hairy to nearly glabrous; leaves and flowers sparsely or moderately hairy to nearly glabrous; common type .
a. *K. scoparia* var. *scoparia*

a. ***Kochia scoparia* var. *scoparia*** Map 846*Kochia scoparia* (L.) Roth [G, BB, P & S]*Kochia prostrata* (L.) Schrad. [P & S]*Kochia alata* Bates, Am. Bot. 24: 52. 1918.

Occurs in waste ground, along railroads and roadsides, where escaped from cultivation. Mostly in some of the counties of northern and central Missouri, especially so along the northwestern section bordering the Missouri River, and locally south in Jasper County.

Native of Eurasia; introduced in the western United States, from where it has spread eastward to New England and southward.

b. ***Kochia scoparia* var. *pubescens*** Fenzl

Map 846

Kochia scoparia var. *subvillosa* Moq.*Kochia scoparia* var. *soongorica* Moq.*Kochia Sieversiana* (Pall.) C. A. Mey.

Known only from Jasper County, southwestern Missouri (rich waste ground, Stockyard Switch, Joplin, August 10, 1949, *Palmer 49750*; September 26, 1949, *Palmer 49835-A*; August 12, 1951, *Palmer 52979*; October 15, 1952, *Palmer 55345*).

- c. ***Kochia scoparia* var. *culta*** Farw. Firebush
Map 846
Kochia scoparia var. *trichophila* (Stapf) Bailey
Kochia trichophylla Stapf

Planted commonly in gardens as an ornamental. Rarely escaping and becoming naturalized in fields and along railroads, from a few scattered localities. The plants turn purplish red to red in autumn.

Kochia scoparia is highly variable. The leaves vary in length, width, and pubescence. *Kochia alata* appears to be one of these variants. The var. *pubescens* is well-

marked as an extreme variation in pubescence.

Large quantities of pollen shed during the summer months by this species account for quite a number of hay fever cases in Iowa, South Dakota, Wyoming, Colorado, Wisconsin, and Minnesota. In Missouri it is too rare to be of any importance in this respect. In Japan and China the plant is grown chiefly for the seeds used as a cereal or in bread. There the young tips of the plant are cooked as a vegetable, and the entire plant, when dried, used as a broom for sweeping.

3. *Chenopodium* L. Goosefoot, Pigweed

Some of the species of this genus can be identified only with mature seeds. The genus has been studied by several botanists in the past four to five decades beginning with Standley in 1916 (N. Am. Fl. 21: 1-93). In 1929 Aellen published on the genus (Fedde Rep. Spec. Nov. Regn. Veg. 26: 31-64, 119-60), and in 1943 Aellen and Just further elaborated (Am. Midl. Nat. 30: 47-76, 1943). The latest work on the North American species by H. A. Wahl (Bartonia 27: 1-46, 1954) is considered by its author as a preliminary study. As many changes in names and in their interpretations have resulted from the studies of these various authors, the synonymy cited below the presently acceptable names indicates the cross-references to these various authors in order to clarify their work and to enable the student to refer to a work which he may have previously followed. The present treatment follows more or less the recent work of Wahl, as indicated above.

- a. Plants aromatic or strongly scented, with simple or glandular hairs or with resinous sessile glands on some parts. b
 - b. Leaves without hairs; stems chiefly hairless, and without glands, the hairs, if present, not spreading; calyx-lobes smooth or minutely puberulent (short-haired), but without conspicuous yellowish glands or stalked glandular hairs; leaf-blades usually 4-15 or more cm. long, the lower ones up to 15 or more cm. 3. *C. AMBROSIOIDES*
 - b. Leaves with obvious hairs; stems glandular and hairy, the hairs spreading; calyx-lobes with either conspicuous yellowish sessile glands or with stalked glandular hairs; leaf-blades small, usually less than 4.5 cm. long, the lower ones longer c
 - c. Calyx-lobes with yellowish sessile glands, hairs if present without glands; leaves coarsely and rather evenly wavy-toothed, the teeth simple, blunt and mainly 1-4 mm. long; flowers in small glomerules (clusters) of the leaf axils; stems ascending mainly from a spreading or nearly prostrate position 1. *C. PUMILIO*
 - c. Calyx-lobes with short-stalked glandular hairs; leaves more deeply and irregularly wavy-lobed (sinuate-pinnatifid), the lobes angled or lobed, the larger ones 3-6 mm. long; flowers in forked spreading short cymes; stems mainly erect 2. *C. BOTRYS*
- a. Plants glabrous (without hairs) or parts of the plant mealy, but not with hairs or yellowish glands; plants not aromatic d
 - d. Lower surface of leaves densely white-mealy e
 - e. Main leaves linear, oblong, narrowly lanceolate, oblong-elliptical, or ovate-lanceolate, 3-many times as long as broad, mostly less than 1.5 cm. broad (occasionally to 2 cm. near base); no teeth or lobes on leaves f
 - f. Leaves 3-nerved or pinnately veined, narrowly lanceolate or broader, mostly broader in the middle or near the base or not of the same width throughout, the sides mostly not parallel; pericarp (covering of fruit) easily removed from seed; seeds 1-1.2 mm. broad; scattered in waste ground and along railroads 7. *C. DESICCATUM*
 - f. Leaves 1-nerved, linear or nearly so with sides mostly parallel to one another, of about the same width throughout; pericarp (covering of fruit) firmly attached to seed, removed with difficulty; seeds 1.2-1.5 mm. broad; plants of rocky and sandy places, glades and bluffs 8. *C. PALLESCENS*
 - e. Main leaves triangular, triangular-rhombic, ovate, or lanceolate to ovate-lanceolate, 1-3 times as long as broad, mostly more than 2 cm. broad; 1, 2, or more teeth or lobes on leaves g
 - g. Leaves mostly 1-3 cm. long, wavy-margined (sinuate); calyx-lobes often 3 or 4 (or 5 in some horizontal flowers which are terminal in the clusters); calyx-lobes flat or rounded with the midrib flat or only slightly thickened or ridged, not definitely keeled; seeds 0.6 mm. broad, mostly vertical; pericarp (covering of fruit) free from the seed, easily removed; calyx-lobes only partially covering fruit 5. *C. GLAUCUM*
 - g. Without the above combination of characters; leaves mostly larger; calyx-lobes 5; calyx-lobes either conspicuously or somewhat keeled in the center; seeds 0.9-1.5 mm. broad, horizontal; pericarp (covering of fruit) usually firmly attached to the seed and removed with difficulty, or free from the seed in *C. desiccatum*; calyx-lobes mostly completely covering the fruit, or only partially covering in *C. strictum* var. *glaucohyllum* h
 - h. Surface of seeds either smooth or with other markings, but not honeycombed i
 - i. Pericarp (covering of fruit) free from the seed, easily removed j
 - j. Stems erect, up to 8 dm. tall; leaves lanceolate to ovate-lanceolate, mostly 3-8 times as long as broad, with only basal lobes 7. *C. DESICCATUM*

- j. Stems low and spreading, up to 4-5 dm. tall; leaves triangular-ovate or rounded-ovate, about as broad as long, often wavy-toothed or lobed 9. *C. INCANUM*
- i. Pericarp (covering of fruit) firmly attached to the seed, removed with difficulty *k*
- k. Seed 1.5-2 mm. broad; surface of seed with a honeycombed appearance 18. *C. BUSHIANUM*
- k. Seed 0.9-1.5 mm. broad; surface of seed more or less smooth *l*
- l. Seeds mainly 1.1-1.5 mm. broad; leaves often very mealy 14. *C. ALBUM*
- l. Seeds 0.9-1.2 mm. broad; leaves often greener *m*
- m. Calyx-lobes only partially covering fruit; lower leaves with short teeth; middle leaves oblong, smooth-edged; flower clusters on erect strict branches; flowering May-September 16. *C. STRICTUM* var. *GLAUCOPHYLLUM*
- m. Calyx-lobes mostly covering the fruit; lower and middle leaves coarsely toothed, at most $1\frac{1}{2}$ times as long as broad; flower clusters on arching branches; flowering September-October. 15. *C. MISSOURIENSE*
- h. Surface of seeds with a honeycombed appearance (alveolate) *n*
- n. Seed 1.5-2 mm. broad; calyx-lobes slightly keeled along center; base of style little if at all prominent; pericarp not showing a yellow area at base of style; leaves rather thin to membranaceous. 18. *C. BUSHIANUM*
- n. Seed 1-1.5 mm. broad; calyx-lobes very prominently keeled along the center, the keel often equaling half the width of the calyx-lobe; base of style often prominent; pericarp showing a yellow area around base of style; leaves rather thick 17. *C. BERLANDIERI*
- d. Lower surface of leaves various shades of green or even tawny or reddish-purple, but not white *o*
- o. Calyx mainly 3-lobed (or 4-5-lobed in horizontal flowers which are terminal in the glomerules); seeds mainly all vertical (except for some of the terminal flowers of the glomerules with horizontal seeds) *p*
- p. Mature flowers in dense heads usually 5-10 mm. in diameter; calyx very fleshy and bright red in fruit, becoming berry-like; seeds all erect or vertical, with an acute or narrow margin, about 1.5 mm. wide 4. *C. CAPITATUM*
- p. Mature flower clusters smaller; calyx in fruit not becoming berry-like; seeds mostly vertical but with a single horizontal terminal flower in the glomerules, with rounded margins, 0.6-0.8 mm. wide 6. *C. RUBRUM*
- o. Calyx 5-lobed; seeds all horizontal (very exceptionally a few vertical) *q*
- q. Surface of seeds with a honeycombed appearance (alveolate) *r*
- r. Seed 1.5-2 mm. broad; calyx-lobes only slightly keeled along center; base of style little if at all prominent; pericarp not showing a yellow area at base of style; leaves rather thin to membranaceous. 18. *C. BUSHIANUM*
- r. Seed 1-1.5 mm. broad; calyx-lobes very prominently keeled along the center, the keel often equaling half the width of the calyx-lobe; base of style often prominent; pericarp showing a yellow area around base of style; leaves rather thick 17. *C. BERLANDIERI*
- q. Surface of seeds either smooth or with other markings, but not honeycombed *s*
- s. Seed 1.5-2.5 mm. broad, either smooth or with indistinct and irregular grooves or wrinkles, easily removed from pericarp (covering of fruit); leaves thin, rounded or heart-shaped at base, long-pointed (acuminate) with large long-pointed teeth; leaf-blades large, mainly 7-17 cm. long and 4-12 cm. wide; often growing along shaded ledges of bluffs or at their base in woodland, or ravines 11. *C. GIGANTOSPERMUM*
- s. Without the above combination of characters; seed smaller, 0.8-1.5 mm. broad, either more or less smooth or with little dots or ridges, easy or hard to remove from pericarp (covering of fruit); leaves thin to thick, with either blunt or long-pointed teeth; leaf-blades usually smaller; either woodland plants or in waste and open ground or other habitats *t*
- t. Pericarp (covering of fruit) not firmly attached to the seed, easy to remove. *u*
- u. Common woodland plant, usually in shaded ground; usually delicate, slender-stemmed plant with thin green leaves and mostly without any mealiness; calyx-lobes flat or rounded, faintly or not at all keeled, only partially covering the mature fruit; seed 1-1.5 mm. broad 10. *C. STANDLEYANUM*
- u. Rare plant, introduced in open waste ground in Jackson Co., western Mo.; low spreading plants with thick leaves and conspicuous mealiness; calyx-lobes with a definite keel in the center, completely covering the mature fruit; seed 0.9-1.1 mm. broad. 9. *C. INCANUM*
- t. Pericarp (covering of fruit) firmly attached to the seed, difficult to remove. *v*

847 *Chenopodium Pumilio*848 *Chenopodium Botrys* (Jerusalem Oak)849 • *Chenopodium ambrosioides* var. *ambrosioides* (Mexican Tea)849 □ *Chenopodium ambrosioides* var. *anthelminticum*

- v. Stigmas short (0.1 mm. or less) and stout; leaves mostly triangular and conspicuously marked with long-pointed (acuminate) teeth; leaf-blades mostly rather thin and shining above w
- w. Calyx-lobes definitely keeled in the center, mealy; seeds 1.2–1.5 mm. broad, dull, with fine ridges or dots over the surface, the margins narrowed or acute; inflorescences shorter than the leaves 12. *C. MURALE*
- w. Calyx-lobes rounded or flat, not keeled, not mealy; seeds 1–1.2 mm. broad, shining, smooth, the margins rounded; inflorescences usually longer than the leaves 13. *C. URBICUM*
- v. Stigmas long or short but not stout; leaves variously shaped and toothed; leaf-blades thick to membranaceous, not shining above x
- x. Seeds mainly 1.1–1.5 mm. broad; leaves often very mealy 14. *C. ALBUM*
- x. Seeds 0.9–1.2 mm. broad; leaves often greener y
- y. Calyx-lobes only partially covering fruit; lower leaves with short teeth; middle leaves oblong, smooth-edged; flower clusters on erect strict branches; flowering May–September . 16. *C. STRICTUM* var. *GLAUCOPHYLLUM*
- y. Calyx-lobes mostly covering the fruit; lower and middle leaves coarsely toothed, at most $1\frac{1}{2}$ times as long as broad; flower clusters on arching branches; flowering September–October 15. *C. MISSOURIENSE*

1. ***Chenopodium Pumilio* R. Br.** Map 847
Chenopodium incanum (S. Wats.) Heller [G, P & S]
Flowers August–October.

Occurs in rocky, sandy, or gravelly ground, in fields, waste ground, along railroads, and about dwellings. Southern Ozark region, where common, northeast to St. Louis County and northwest locally in Jackson County.

Native of Australia; introduced into the United States where naturalized in Massachusetts, New York, New Jersey, Pennsylvania, D. C., and from Missouri to Texas and California.

2. ***Chenopodium Botrys* L.** Jerusalem Oak Map 848

Also known as Feather Geranium.
Flowers July–October.

Occurs in waste ground and along railroads. Infrequent and scattered in southern and central Missouri north to St. Louis and Jackson counties.

Native of Eurasia; introduced into North America, where naturalized from Quebec to Washington, south to Virginia, Kentucky, Missouri, and California.

This species may cause some cases of hay fever, but is not common enough in Missouri to be of any present concern.

3. ***Chenopodium ambrosioides* L.** Map 849
Mexican Tea, Wormseed
Flowers August–November.

Occurs in rich waste ground, on dumps, fields, along railroads, and about dwellings. Scattered throughout the state, but not recorded from the northernmost counties.

Missouri material may be divided into two varieties:

- Inflorescences interrupted with leaves or leafy bracts; calyx-lobes slightly keeled. 3a. *C. AMBROSIOIDES* var. *AMBROSIOIDES*
- Inflorescences mostly without leaves or leafy bracts; calyx-lobes not keeled . 3b. *C. AMBROSIOIDES* var. *ANTHELMINTICUM*

- 3a. ***Chenopodium ambrosioides* var. *ambrosioides*** Map 849
Chenopodium ambrosioides ssp. *eu-ambrosioides* Aellen [Aellen, Aellen & Just]

850 *Chenopodium capitatum* (Strawberry Blite)851 • *Chenopodium glaucum* var. *glaucum* (Oak-leaved Goosefoot)851 □ *Chenopodium glaucum* var. *salinum*852 *Chenopodium rubrum* var. *rubrum* (Coast Blite)

This is the more commonly collected variety in the state, recorded north to Marion, Linn, and Livingston counties; probably in most of the counties in the state.

Native of tropical South and Central America, Mexico, and the West Indies; naturalized in the United States and Canada, ranging north to Maine, New York, Ontario, Wisconsin, Iowa, and California.

3b. ***Chenopodium ambrosioides* var. *anthelminticum* (L.) Gray** Map 849

Chenopodium ambrosioides ssp. *eu-ambrosioides* var. *anthelminticum* (L.) Aellen [Aellen, Aellen & Just]

Apparently less frequently found in Missouri, where recorded north to St. Louis, Boone, Howard, and Jackson counties.

Native of tropical America; naturalized in the United States, in some sections more common than var. *ambrosioides*.

Aellen has divided *C. ambrosioides* into 5 subspecies with a number of varieties and numerous forms. The two variations in Missouri have been treated in the present flora as varieties and await further studies by other workers.

This species is sometimes grown for the oil which is used as an efficient agent for getting rid of intestinal parasites, such as hook-worm. For this purpose it is frequently used in the southern United States, Mexico, and parts of Central and South America. In some parts of Guatemala it is used for flavoring food, as a poultice, and as a narcotic for inducing sleep. Stock usually do not eat the plant. A few cases have been recorded of poisoning from taking too large quantities of the oil. The large amount of pollen shed sometimes is considered important in causing cases of hay fever. Although many species of *Chenopodium* are cooked as green vegetable, this one should not be used because of its possible poisonous effects from the oil contained.

4. ***Chenopodium capitatum* (L.) Aschers.**

Strawberry Blite

Map 850

Also known as Strawberry Spinach.

Flowers May–August.

Occurs in waste ground in Pike County, northeastern Missouri.

Ranges from Nova Scotia and Quebec to Alaska, south to New Jersey, Pennsylvania, Michigan, Indiana, Illinois, Wisconsin, Missouri, Minnesota, New Mexico, and California; also in Eurasia.

Where it is more common farther north, the fleshy fruits are sometimes eaten, raw or cooked, and the plant cooked as a spinach substitute.

5. ***Chenopodium glaucum* L. Oak-leaved Goosefoot** Map 851

Flowers May–October.

Occurs in alluvial muddy soils along the Missouri River, around ponds, open waste ground, and along railroads.

Missouri material is represented by two variations:

Tip of leaf and teeth of margins obtuse or blunt; flower-clusters mostly without bracts. 5a. *C. GLAUCUM*

var. *GLAUCUM*

Tip of leaf and teeth of margins acute; flower-clusters mostly with bracts. 5b. *C. GLAUCUM*

var. *SALINUM*

garded as an important cause of hay fever, but in Missouri is too rare to be of any present concern.

5b. ***Chenopodium glaucum* var. *salinum***

(Standley) Boivin

Map 851

Chenopodium salinum Standl. [G, BB]

Chenopodium glaucum ssp. *salinum* (Standley) Aellen [Aellen & Just]

Known from St. Louis County, east-central Missouri (St. Louis, freight yard (Burlington) in northern part south of switch 11, June 30, 1956, *Muehlenbach* 975). The plant, determined by Wahl, is one of two specimens under this number collected by Dr. Muehlenbach, the other specimen being determined as typical var. *glaucum*.

Ranges from Manitoba to Iowa and Missouri, west to Oregon and Arizona.

6. ***Chenopodium rubrum* L. var. *rubrum***

Coast Blite

Map 852

Chenopodium rubrum L. [G, BB, Aellen, Aellen & Just]

Flowers July–November.

Known only from Jackson County, west-central Missouri (July 15, 1892, *Bush*, World's Fair specimen in Univ. of Mo. Herb.).

Ranges from Newfoundland to Washington, south to New Jersey, New York, Missouri, Nebraska, New Mexico, Arizona, and California; also in Europe.

7. ***Chenopodium desiccatum* A. Nelson** Map 853

Flowers early June–October.

Occurs in waste and open ground and along railroads.

Missouri material is represented by two variations:

Leaves not lobed, mostly oblong-elliptic, rather thick; calyx-lobes more green than yellow, blunt or obtuse, more prominently keeled in the center; plants varying from low and spreading to erect-spreading . . . *C. DESICCATUM* var. *DESICCATUM*
Leaves lobed or not lobed, lanceolate to ovate-lanceolate; calyx-lobes more yellowish than green, acute or short-pointed, less prominently keeled in the center; plants erect . . . *C. DESICCATUM* var. *LEPTOPHYLLOIDES*

[G, BB, P & S in part]

Chenopodium leptophyllum var. *leptophylloides* (Murr.)

Thellung & Aellen [P & S in part]

Chenopodium pratericola var. *Thellungianum* Aellen

Occurs in waste ground and along railroads. Scattered in St. Louis (Muehlenbach 61, 222), and Jackson (Kansas City, Bush 9424; Courtney, Bush 9021, 9034) counties.

Ranges from New Jersey, Indiana, Illinois, Missouri, Nebraska, North Dakota, Montana, Idaho, and Washington, south to Virginia, Louisiana, Texas, New Mexico, Arizona, and California; also in Mexico and South America.

Material properly placed in *C. pallescens* has been confused with this species and with *C. leptophyllum* Nutt. Typical *C. leptophyllum* Nutt. is not known in Missouri.

3. ***Chenopodium pallescens* Standley** Map 854

Chenopodium leptophyllum of auth. in part, not Nutt.

[G, BB, P & S]

Chenopodium leptophyllum var. *leptophylloides* of some

auth., not (Murr.) Thellung & Aellen [P & S]

Chenopodium subglabrum [of BB in part], not (Wats.)

A. Nels.

Flowers early June–October.

Occurs on rocky or sandy open ground, along edges of bluffs, quarries, limestone outcrops and glades, waste ground, and along railroads.

Scattered throughout northern, central, and western Missouri, south to Jefferson, Gasconade, Morgan, and Jasper counties, and locally south in Dunklin and Howell counties.

Ranges from Indiana, Missouri, and Oklahoma to Texas and New Mexico.

This species has been confused previously by various authors with *C. leptophyllum* of auth., not Nutt. (= *C. desiccatum* and variety *leptophylloides*). Most of the specimens previously cited in Palmer & Steyermark's *Annotated Catalogue* as *C. leptophyllum* and var. *lepto-*

phylloides, and specimens, labeled as such in various herbaria, should be referred to *C. pallescens*, characterized by the thick, linear 1-nerved leaves without any teeth or lobes and with the pericarp firmly attached to the seed.

9. ***Chenopodium incanum* (S. Wats.) Heller**

Map 855

Flowers June–October.

Known only from waste ground in Jackson County, west-central Missouri (Courtney, June 18, 1920, Bush 8984).

Ranges from Missouri, Nebraska, South Dakota, Colorado, Nevada, and California, south to Oklahoma, Texas, New Mexico, and Arizona; also in Mexico.

10. ***Chenopodium Standleyanum* Aellen**

Map 856

Chenopodium Boscianum Moq. of auth. [G], not as to type.

Flowers June–October.

Occurs in woodland, shaded thickets, dry or moist soil, rocky or rich ground, and shaded ledges of bluffs. Throughout Missouri; probably in every county.

Ranges from Florida to Texas, north to Connecticut, Quebec, Ontario, Minnesota, and North Dakota.

This is an easily recognizable species, with its combination of relatively thin, mostly dull green, often entire leaves, small interrupted slender inflorescences, rounded calyx-lobes which do not cover the fruit, mostly delicate, slender habit, and woodland habitat.

11. ***Chenopodium gigantospermum* Aellen**

Maple-leaved Goosefoot

Map 857

Chenopodium gigantospermum var. *Standleyanum* Aellen

Chenopodium hybridum var. *gigantospermum* (Aellen)

Rouleau [G]

859 *Chenopodium urbicum* (City Goosefoot)860 • *Chenopodium album* var. *album* (Pigweed)
860 □ *Chenopodium album* var. *lanceolatum*861 *Chenopodium missouriense**Chenopodium hybridum* var. *Standleyanum* (Aellen) Fern. [G]

Flowers June–October.

Occurs along shaded ledges of bluffs, at the base of rocky wooded slopes and bluffs, especially of limestone, and in rich or fertile open soils or in woodland. Common in most parts of the state; not recorded from the southeastern and most of the northeastern sectors, but of expected occurrence in most counties.

Ranges from Quebec to British Columbia, south to Virginia, Kentucky, Missouri, Oklahoma, Texas, New Mexico, and California.

This is another easily recognized species in the genus by virtue of the large, thin, rich green leaves, which taper to a long acuminate apex and are rounded or subcordate at the base, have conspicuous acuminate large teeth or lobes, and have large, leafless clusters of flowers with relatively large seeds.

By some authors this is considered as only a variety of the European *C. hybridum* L. Besides the larger seeds of the American plants, Wahl (Bartonia 27: 30. 1954) contrasts the two in such other respects as the thick, black, strongly reticulate, attached pericarp of *C. hybridum* instead of the thinner, greenish-transparent, less reticulate pericarp of *C. gigantospermum* which is usually more separable and easily removed from the seed, although attached also, by the more rounded margin of the seed in *C. hybridum*, by the broad sepals with contrasting green center and pale margins covering more of the fruit in *C. hybridum* instead of the narrow sepals with less contrast in color of *C. gigantospermum*, and by differences in the inflorescence and base of leaves.

12. *Chenopodium murale* L.

Nettle-leaved Goosefoot

Map 858

Flowers June–November.

Occurs in waste ground and about dwellings. Scattered in central and southern Missouri, north to

St. Louis, Warren, Boone, and Jackson counties. Undoubtedly of wider occurrence when the state has been more thoroughly collected.

Native of Europe; naturalized in North America, from Quebec to British Columbia, south throughout the United States.

13. *Chenopodium urbicum* L. City Goosefoot

Map 859

Chenopodium urbicum var. *intermedium* (Mert. & Koch)

Koch [P & S]

Flowers July–October.

Occurs in waste ground, dumps, and about dwellings. Rarely collected, known only from St. Louis, Boone, and Greene counties.

Native of Europe; naturalized in North America from Quebec to Ontario and Wisconsin, south to Maryland, West Virginia, Indiana, Illinois, and Missouri; also naturalized on the Pacific Coast, and South America.

Both this species and *C. murale* are similar to *C. gigantospermum* in having rich green, rather thin leaves with sharply pointed teeth. The leaves, however, are generally smaller and more broadly triangular than those of *C. gigantospermum* and wedge-shaped or truncate instead of rounded to subcordate.

14. *Chenopodium album* L.

Pigweed, Lamb's Quarters

Map 860

Flowers May–October.

Occurs in waste and cultivated ground and along railroads. Throughout Missouri, and probably in every county.

A very variable species, the following variations of which are recognized in Missouri based upon Dr. Wahl's studies:

Plants with erect branches; flower-clusters mostly in contact with each other, without conspicuous separated intervals between; calyx-lobes more

frequently pointed and with yellow margins; all the individual flowers sessile (without stalks); leaves usually broadly ovate and prominently toothed, varying to lanceolate nontoothed bracts

14a. *C. ALBUM* var. *ALBUM*

Plants with spreading branches; flower-clusters conspicuously separated from one another; calyx-lobes more frequently blunt (obtuse) and with white margins; some of the individual flowers on stalks; leaves narrowly ovate to lanceolate, those of the inflorescence without teeth. . . 14b. *C. ALBUM*

var. *LANCEOLATUM*

- 14a. ***Chenopodium album* var. *album*** Map 86o
Chenopodium album L. [G, BB, P & S, Steyerm.]
Chenopodium album ssp. *eu-album* (Ludwig) Aellen
var. *polymorphum* Aellen [Aellen & Just]
Throughout Missouri.

Throughout the United States and Canada; also in Eurasia. Both native North American and introduced Old World races of this species are interpreted as *C. album* var. *album*.

According to Wahl (Bartonia 27: 34. 1954), var. *album* is a plant of cultivated places, in usually disturbed soils, such as gardens and cornfields.

- 14b. ***Chenopodium album* var. *lanceolatum***

(Muhl.) Coss & Germ. Map 86o

Chenopodium album f. *lanceolatum* (Muhl.) Aellen [P & S, Aellen & Just]

Chenopodium album f. *viride* (L.) Aellen [P & S, Aellen & Just]

Chenopodium album ssp. *eu-album* var. *polymorphum* f. *glomerulosum* (Reichenb.) Aellen [Aellen & Just]

Chenopodium album ssp. *eu-album* var. *polymorphum* f. *cymigerum* (Koch) Aellen [Aellen & Just]

Scattered throughout Missouri, and probably more common after thorough collecting has been done.

According to Wahl (above), var. *lanceolatum* is a plant of both cultivated and undisturbed soil, often persisting in waste ground, and in cities and towns. Future studies of the respective habitats of var. *album* and var. *lanceolatum* in Missouri may throw additional light on this phase of the subject.

The present author believes that Dr. Wahl's conservative treatment of the variations of *C. album* is more justified than that of Aellen which recognizes additional subspecies, varieties, and forms.

This species, and those following in this treatment, make excellent spring greens, the tender young shoots and leaves being cooked alone as a substitute for spinach or in combination with such other greens as *Amaranthus*, *Lactuca*, *Sonchus*, *Rumex*, and *Phytolacca*. American Indians prepared a type of bread and

porridge from the richly nutritious seeds of various species of this genus, of which *C. album* is one. In the Andean countries of South America, particularly in Ecuador, Peru, and Bolivia, *C. Quinoa* or Quinoa produces large quantities of nutritious seeds consumed by the Indians of those countries in soups, bread, and cakes. A fermented drink is also prepared by them from these seeds.

In its earlier period of growth, while the stems are still soft, this and the other similar and related following species of *Chenopodium* may be plowed under as a green manure to enrich the soil, or fed to poultry and hogs as green food. The abundant pollen produced by this and other species similar in appearance is considered to be responsible for causing hay fever in some areas where the species are abundant. In fall the foliage of this and related species turns bronze to purplish-red.

15. ***Chenopodium missouriense*** Aellen Map 86i
Chenopodium missouriense var. *Bushmanum* Aellen [P & S, Aellen & Just]

Chenopodium paganum Standl. [Standl.]

Chenopodium album of some auth. [BB in part], not L.
Chenopodium Berlandieri of some auth. [G in part], not Moq.

Flowers September–October.

Occurs in waste ground and along railroads. Scattered in Missouri, but doubtless in most of the counties.

Ranges from Florida to Texas, north to New England, Pennsylvania, Ohio, Michigan, Indiana, Illinois, Wisconsin, and Minnesota.

The var. *Bushmanum* Aellen, distinguished by Aellen on the basis of the mealy lower surface of the leaves, does not merit distinction, since both mealy and non-mealy leaves may be present on the same plant, or various degrees of mealiness may be found on the same plant.

The strictly autumnal flowering of this species is considered an easy mark of recognition to separate it from *C. album*, which begins to flower in May.

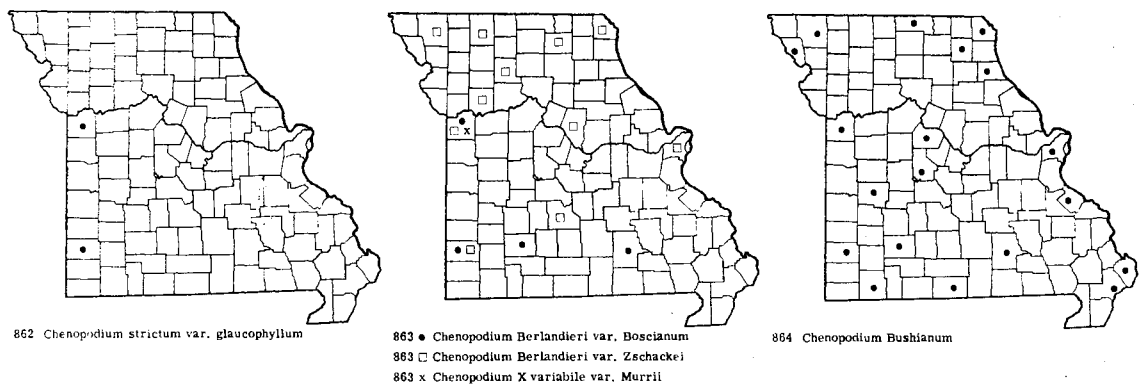

16. ***Chenopodium strictum*** Roth var. ***glaucophyllum*** (Aellen) Wahl Map 862

Chenopodium glaucophyllum Aellen [P & S]

Chenopodium strictum ssp. *glaucophyllum* (Aellen) Aellen [Aellen & Just]

Flowers July–September.

Occurs in waste ground. Known only from western Missouri in Jasper (Webb City, August 6, 1920, *Bush 9061A*) and Jackson (Sheffield, Courtney, *Bush 8065*, *8065A*, *8095*, *8108*, *8110*, *8111*, *8195A*, *8546B*, and others by Bush) counties.

Ranges from Quebec to Manitoba south to Connecticut, New York, Pennsylvania, Michigan, Illinois, Missouri, Arkansas, Nebraska, and California.

Chenopodium strictum var. *strictum* is Asiatic and differs in the more prominently serrate oblong-ovate leaves 3 or more times as long as broad instead of only twice as long as broad as in var. *glaucophyllum*. The small seeds combined with the shallowly serrate, oblong lower leaves are considered the best marks of distinction of *C. strictum* var. *glaucophyllum*.

- 17. **Chenopodium Berlandieri** Moq. Map 863
Flowers June–October.
Occurs in waste and cultivated ground and along railroad tracks.

Many subspecies (8), varieties (6), and forms (9) have been published by Aellen under this species and are to be found categorized in their respective details in Aellen and Just's work (Am. Midl. Nat. 30: 71–73, 1943). The following key and treatment of Missouri material is in accordance with Dr. Wahl's paper (Bartonia 27: 40–44, 1954):

- a. Leaves membranaceous, 2–4 cm. long, rhombic-triangular, conspicuously dentate or the upper ones becoming entire; upper portions of the inflorescence becoming bractless; seeds 1–1.3 mm. in diameter . . . 17a. *C. BERLANDIERI* var. *BOSCIANUM*
- a. Leaves more often thicker, but also thin, variable in size and shape but larger than 4 cm. long; sepals strongly keeled; inflorescence leafy; seeds 1.2–1.5 mm. in diameter . . . 17b. *C. BERLANDIERI* var. *ZSCHACKEI*

- 17a. **Chenopodium Berlandieri** var. **Boscianum** (Moq.) Wahl Map 863
Chenopodium Berlandieri ssp. *Boscianum* (Moq.) Aellen [P & S, Aellen & Just]
Chenopodium Boscianum Moq., in part, not of Am. auth.

Occurs in waste ground. Known from Jackson, Jasper, Greene, and Shannon counties in southern and central Missouri.

Ranges from Florida to Texas, north to Virginia and Missouri.

- 17b. **Chenopodium Berlandieri** var. **Zschackei** (Murr.) Murr. Map 863
Chenopodium Berlandieri ssp. *Zschackei* (Murr.) Zobel [Aellen & Just]
Chenopodium Berlandieri Moq. in part [G]
Chenopodium album in part [BB], not L.
Chenopodium Berlandieri ssp. *Zschackei* var. *foetens* (Ludwig) Aellen [P & S, Aellen & Just]
Chenopodium Berlandieri ssp. *Zschackei* var. *farinosum* (Ludwig) Aellen [P & S, Aellen & Just]
Chenopodium Berlandieri ssp. *Zschackei* var. *typicum* (Ludwig) Aellen [P & S, Aellen & Just]
Chenopodium Berlandieri ssp. *Zschackei* var. *typicum* f. *angustius* (Ludwig) Aellen [P & S, Aellen & Just]
Chenopodium Berlandieri ssp. *Zschackei* var. *typicum* f. *latifolium* (Ludwig) Aellen [P & S, Aellen & Just]
Chenopodium Berlandieri ssp. *Zschackei* var. *typicum* f. *pedunculare* Aellen [P & S, Aellen & Just]
Chenopodium Berlandieri ssp. *Zschackei* var. *typicum* f. *neglectum* Aellen [P & S, Aellen & Just]
Chenopodium dakoticum Standley [P & S, Standley]
Concurring with the preliminary conclusions reached by Dr. Wahl, it will be noted that numerous varieties and forms treated as such by Aellen and by Aellen and Just are considered in the present flora as variations within var. *Zschackei* not meriting recognition.

By Aellen and Just var. *typicum* is considered a slightly mealy to nearly glabrous variation, while var. *foetens* and var. *farinosum* (syn. *C. dakoticum*) are abundantly white-mealy; var. *foetens* is distinguished by having short, obtuse, slightly 3-lobed leaves often with a rank odor, whereas var. *farinosum* has shorter, ovate-elliptic, dentate leaves without an odor. Under

var. *typicum* forms involving Missouri material are based upon narrower leaves with a longer tip (f. *angustius*), broader leaves often somewhat rounded at tip (f. *latifolium*), terminal inflorescence large and cymose (f. *pedunculare*), and inflorescence short, axillary, and cymose (f. *neglectum*). All these varieties and forms are based upon specimens collected by Bush from Jackson County.

The var. *Zschackei* occurs in waste ground scattered in various parts of Missouri, and of expected occurrence in nearly every county of the state.

Ranges from Ontario to James Bay and Mackenzie Basin, south to Virginia, Pennsylvania, Illinois, Arkansas, Oklahoma, Texas, New Mexico, Arizona, and California.

17c. A supposed hybrid between *Chenopodium album* and *C. Berlandieri* var. *Zschackei* known as **Chenopodium** × **variable** var. **Murrii** Aellen has been collected by Bush in Jackson County, west-central Missouri.

18. **Chenopodium Bushianum** Aellen Map 864
Chenopodium album of some auth. in part [BB], not L.

Chenopodium paganum of Am. auth. [G, Standley, P & S], not Reichenb.

Flowers August–October.

Occurs in sandy fields and alluvial ground along rivers, waste places, wooded slopes, and dry open or shaded ground. Scattered throughout Missouri, and of expected occurrence in nearly every county of the state.

Ranges from Quebec to Alaska, south to Virginia and Missouri.

The reticulate large seeds and large thin leaves are characters which separate this species from related ones. The leaves have a paler green color than those of *C. album* or *C. missouriense*, and the usually lead-grey, drooping irregular inflorescences, on plants which are often leafless by autumn, further serve as aids in identifying *C. Bushianum*.

4. **Atriplex** Orach

- a. Branches and leaves mainly opposite in the lower half of the plant; leaves mainly green or only slightly gray-green, mostly without teeth (entire) or slightly toothed or with spreading lobes at base; stem mainly green, pale green, or slightly gray-green; fruiting bracts which surround the fruit are usually without teeth (entire) or only minutely toothed, soft or thin and easily separating from each other, their margins free to below the middle. b
- b. Larger leaf-blades mainly 8–20 cm. (less frequently 3.5–7 cm.) long; fruiting bracts which surround the fruit 10–15 mm. broad, with conspicuous reticulate venation (net-like); pistillate (pistil-bearing) flowers with a 3–5-lobed calyx; rarely encountered, known only from St. Louis and Jackson counties, central Missouri. 1. A. HORTENSIS
- b. Larger leaf-blades 2.5–8 cm. long; fruiting bracts which surround the fruit 2–6 mm. broad, without prominent venation; pistillate (pistil-bearing) flowers without any calyx; scattered in northern, central, and western sections of Missouri. 2. A. PATULA
- a. Branches and leaves alternate in the lower half of the plant; leaves gray-silvery or whitish-gray, mostly toothed; at least the young stems gray-silvery or whitish-gray, the older becoming straw-colored; fruiting bracts which surround the fruit are toothed, hard and firm, their margins united to at least the middle or above the middle or free only in the upper half. c
- c. Fruiting bracts surrounding the fruit dentate (merely toothed) along the sides, broadly ovate to rhombic, with a broad or spreading base, broadest in the lower half, united to the middle, free in the upper half. 3. A. ROSEA
- c. Fruiting bracts surrounding the fruit lacerate or deeply toothed across the summit, rounded and somewhat wedge-shaped with a slightly tapering base, broadest at the middle or upper half, united to above the middle, free only in the upper third. 3. A. ARGENTEA

1. **Atriplex hortensis** L. Garden Orach

Map 864A

Flowers August–October.

Occurs in waste and fallow ground. Known only from St. Louis (introduced, nearly spontaneous, St. Louis, August, 1839, *Engelmann*) and Jackson (introduced, Sheffield, June 10, 1907, *Bush 4799*) counties, central Missouri.

Native of Asia; introduced in North America, from Quebec and New England to Montana, south to New York, Kentucky, Missouri, Colorado, and Utah.

This species is sometimes grown as a garden vegetable and used like spinach for greens. The foliage is normally green, but crimson-leaved plants (var. *atrosanguinea* Hort.), sometimes over 1 meter tall, are

864A *Atriplex hortensis*

865 • *Atriplex patula* var. *patula* (Orach)
□ *Atriplex patula* var. *hastata*

866 *Atriplex rosea* (Red Scale)

cultivated as ornamentals. The small flowers are often purplish.

2. ***Atriplex patula* L.** Orach, Spear Scale Map 865

Flowers early June–November.

Occurs in cultivated or waste ground, dumps, and along railroads.

Two variations are represented in Missouri material:

Main leaves triangular or arrowhead-shaped with spreading lobes, often toothed; fruiting bracts truncate (as if cut straight across) or broadly rounded at base. 2b. *A. PATULA* var. *HASTATA*

Main leaves oblong or lanceolate, mostly without teeth or with a few low teeth; fruiting bracts slightly narrowed or narrowly rounded at base

2a. *A. PATULA* var. *PATULA*

2a. ***Atriplex patula* var. *patula*** Map 865

Atriplex patula L. [G, P & S]

Scattered in northern and central Missouri.

Ranges from Newfoundland to British Columbia, south to Florida, Alabama, Missouri, and California; also in Eurasia.

2b. ***Atriplex patula* var. *hastata* (L.) Gray** Map 865

Scattered in central and western Missouri.

Ranges from Newfoundland to British Columbia, south to South Carolina, Ohio, Indiana, Illinois, Missouri, Texas, and California.

In the western states *Atriplex patula* is one of the species causing hay fever during the summer months, and is considered as an especially important cause of hay fever in parts of California. The young growing tips and leaves may be cooked for greens, and are considered superior to *Chenopodium album* and related species.

3. ***Atriplex rosea* L.** Red Scale Map 866

Also known as Red Orach.

Flowers August–October.

Occurs in salt-impregnated soils bordering saline or sulfur springs and in waste ground and along railroads. Known only in central Missouri from St. Louis, Howard (alkaline ground along Salt Creek and adjacent salt springs at Boonslick, 3 mi. west of Boonsborough, August 23, 1934, *Steyermark 14785*), and Jackson counties. In Howard County this species is found around a saline spring.

Native of Eurasia; introduced into the United States, where naturalized from New York to Wisconsin, south to Florida, Missouri, and Kansas; in the western states from Wyoming to Washington, south to California; also Mexico and the West Indies.

In some of the western states this *Atriplex* is considered as one of the important hay fever contributing species.

4. ***Atriplex argentea* Nutt.** Silver Scale Map 867

Also known as Saltbrush.

Flowers June–October.

Occurs in waste ground and along railroad tracks. Known only from St. Louis (along railroad near Lead Works, 5500 Manchester Ave., St. Louis, September 22, 1939, *Petersen*; North St. Louis, Burlington freight yard, June 30, 1956, *Muehlenbach 974*) and Jackson (Courtney, July 16, 1907, *Bush 4813*) counties.

Ranges from Manitoba and Saskatchewan to Montana, south to Kansas, Oklahoma, Texas, New Mexico, and California; introduced eastward to Michigan, Ohio, and Missouri.

The upper leaves are very short-petioled to nearly sessile. The species is considered an important cause of hay fever in the western states.

867 *Atriplex argentea* (Silver Scale)868 *Axyris amaranthoides* (Russian Pigweed)869 *Monolepis Nuttalliana* (Poverty Weed)

5. *Axyris* L.

Axyris amaranthoides L. Russian Pigweed

Map 868

Flowers May–October.

Known only from Jackson County (May, 1918, *Bush 8308*), west-central Missouri, where introduced in waste ground. Not found since the early collection

by Bush.

Native of Siberia; introduced into North America, ranging from Quebec to Alberta, south to Massachusetts, Missouri, Nebraska, North Dakota, and westward.

6. *Monolepis* Schrad.

Monolepis Nuttalliana [R. & S.] Greene

Poverty Weed

Map 869

Flowers late May–October.

Occurs in waste ground and along railroad tracks. Known only from St. Louis (Bremen Ave. freight yard of Terminal Railroad Association, June 2, 1956, *Muehlenbach 907*) and Jackson (along railroad, Courtney, May 18, 1918, *Bush 8276*) counties.

Ranges from Minnesota and Manitoba, south to Missouri, Oklahoma, Texas, New Mexico, and Califor-

nia; also in Mexico, and introduced in New England.

This is usually a low-growing plant from 0.4–2 dm. tall, rarely becoming 4–5 dm. The stems and leaves are mainly glabrous or with sparse, scattered mealy granules. The leaves are usually narrow and petioled, and the small sessile flowers are in little clusters in the axils of the upper and middle leaves. The plant at first superficially resembles a dwarfed *Kochia scoparia* or *Salsola Kali* var. *tenuifolia* until the toothed leaves and floral characters are observed.

7. *Corispermum* L. Bugseed

- a. Fruit lacking a wing or practically so 3. *C. ORIENTALE* var. *EMARGINATUM*
 a. Fruit with a definite wing along the margin b
 b. Fruit 3.5–4.5 mm. long; spikes of flowers or fruits dense and continuous except at very base; bracts of flowers and fruits conspicuously overlapping, at least the middle and upper ones hiding the main axis and longer and broader than the fruits, and the lower bracts broader than the fruits

- b. Fruit 2–3 mm. long; spikes of flowers or fruits slender and rather interrupted; bracts of flowers and fruits not overlapping, and more separated, exposing the main axis, the upper bracts only slightly if at all longer than the fruits, the lower bracts much narrower than the fruit. . . . 2. *C. NITIDUM*

1. ***Corispermum hyssopifolium* L.** Bugseed

Map 870

Flowers August–October.

Occurs on sand dunes and flats along the Missouri and Mississippi rivers in western, central, and eastern Missouri. Records are from only Clay, Jackson, Ray, St. Louis, and Perry counties, but doubtless to be found in sandy situations along all the counties bordering the Missouri and Mississippi rivers.

Ranges from Quebec to Washington, south to Indiana, Illinois, Missouri, Oklahoma, New Mexico, and Arizona. Introduced along railroads eastward to New York. Also in Mexico and Eurasia.

2. ***Corispermum nitidum* Kit.**

Map 871

Flowers August–October.

Occurs in sandy and waste ground. Known only from Clark (introduced, Medill, August 23, 1920, *Bush* 9153) and Jackson (sands, Courtney, August 27, 1905, *Bush* 3284) counties.

Ranges from Indiana to Idaho, south to Missouri, Kansas, Texas, and Arizona; also in Europe.

3. ***Corispermum orientale* Lam. var. *emarginatum* (Rydb.) Macbr.**

Map 872

Corispermum villosum Rydb.

Flowers August–October.

Known only from sandy open places in Jackson County, west-central Missouri (sandy bottoms, Courtney, September 4, 1933, *Bush* 12964).

Ranges from Alberta to Colorado and Nevada east to Missouri.

8. ***Suaeda* Forsk.** Sea Blite

***Suaeda depressa* (Pursh) Wats.** Sea Blite

Map 873

Flowers July–October.

Known only from Jackson County, west-central Missouri (July 15, 1892, *Bush*, World's Fair specimen in Univ. of Mo. Herb.).

Ranges from Minnesota and Manitoba to Montana, south to Missouri, Kansas, Texas, Nevada, and California; introduced in Missouri.

The fleshy tender leaves and branches of this and other species of the genus are sometimes cooked as a vegetable in those areas where the plants abound.

9. ***Salsola* L.** Saltwort, Russian Thistle

***Salsola Kali* L.** Saltwort, Russian Thistle

Map 874

Flowers July–October.

Occurs in dry, sandy, rocky, or open ground, waste places, along roadsides, and railroads.

Missouri material is represented by two variations:

Main leaves usually 1–2 mm. broad, tapering gradually upward from a broader base, up to 3 cm. long, all stiff and spiny-pointed; fruiting calyx 6–10 mm. wide; rarely found in Missouri

a. *S. KALI* var. *KALI*

Main leaves about 1 mm. broad, threadlike. usually 3–7 cm. long, especially those on the

873 *Suaeda depressa* (Sea Blite)

874 • *Salsola Kali* var. *Kali* (Saltwort)
874 □ *Salsola Kali* var. *tenuifolia* (Russian Thistle)

875 *Celosia argentea* var. *cristata* (Cockscomb)

younger and leafy stems, fruiting calyx 3–6 mm. wide; the more commonly encountered type found b. *S. KALI* var. *TENUIFOLIA*

a. ***Salsola Kali* var. *Kali*** Saltwort Map 874
Salsola Kali L. [G, P & S]
This is rarely found in Missouri, and known only from Jackson and Jasper counties.

Ranges from Newfoundland and Quebec, south along the coast to Georgia and Louisiana, rarely inland; also in Eurasia.

b. ***Salsola Kali* var. *tenuifolia*** Tausch. Map 874
Russian Thistle
The more commonly found variation occurs along sand bars and flats of the Missouri and Mississippi rivers, especially more common in the northwestern and west-central sectors, south locally to Jasper, Lawrence, and St. Francois counties.
Native of Asia; introduced into the United States,

where ranging from Quebec to British Columbia, south to North Carolina, West Virginia, Ohio, Indiana, Illinois, Missouri, Kansas, Texas, and California.

The flowers are at first greenish, but the fruiting calyx becomes pinkish. *Salsola Kali* var. *tenuifolia* is considered to cause more cases of hay fever than any other member of the Chenopodiaceae, and, where it is more common than the ragweeds in some of the prairie regions and western states, it is thought to be the main cause of many cases of hay fever in those areas.

Although the plant has been much and justifiably maligned as a weed, it makes nourishing food for livestock when put up and cured for hay, and the young plants are eaten by grazing animals. In years of drouth in some of the western states it has carried over livestock in otherwise impoverished soils, and also has helped to build up loose soils in windblown sections of the western states.

Fam. **AMARANTHACEAE** (Amaranth Family)

The genus *Acnida*, formerly maintained as a distinct genus, is now combined with *Amaranthus*, according to the recent studies of Dr. Sauer (Madroño 13: 5–46. 1955), whose work is here followed.

- a. Leaves alternate b
- b. Flowers white, pink, red, or orange, in a broad and flattened fasciated (enlarged and grown together) mass; flowers perfect (stamens and pistil in the same flower); ovary with 2 or more ovules or seeds; filaments of stamens united at the base 1. CELOSIA
- b. Flowers green, straw-colored, or rarely shades of red, in usually long and narrow simple or branched spikes or panicles or short axillary clusters; stamens and pistils usually separated on different flowers on the same (monoecious) or different (dioecious) plants, or polygamous (both perfect and unisexual flowers present); ovary with 1 ovule or seed; filaments of stamens separate and distinct 2. AMARANTHUS
- a. Leaves opposite c
- c. Low sprawling plant, often lying on the ground; leaves 1–3 cm. long; stem and leaves covered with tiny star-shaped hairs (stellate pubescence), the uppermost leaves gray-white with a dense pubescence; flowers along the stem in the axils of the leaves 3. TIDESTROMIA
- c. Stems mainly and eventually erect; leaves mainly 3–12 cm. long; stem and leaves glabrous or

- hairy, but, when hairy, the hairs simple, not star-shaped; flowers in inflorescences at the ends of the stems d
- d. Leaves with definite petioles (stalk); leaf-blade thin, ovate, the lower surface glabrous or sparsely hairy; flowers in a branching panicle 4. IRESINE
- d. Leaves sessile (without a stalk) or nearly sessile; leaves thickish, linear, narrowly lanceolate, or elliptical-lanceolate, the lower surface densely woolly- or silky-hairy; flowers in an unbranched narrow, slender or thick spike 5. FROELICHIA

1. *Celosia* L. Cockscomb

***Celosia argentea* L. var. *cristata* (L.) Ktze.**

Cockscomb

Map 875

Flowers July–October.

Commonly cultivated as an ornamental annual, and rarely escaped along railroads and waste ground, where known in Missouri only from St. Louis County (Mo. Pac. R.R., north of Dover St., St. Louis, September 14, 1957, *Muehlenbach* 1364; Mo.-Kan.-Tex.

R.R., Baden freight yard, St. Louis, September 1, 1957, *Muehlenbach* 1334).

Native of tropical America; introduced into the United States, and generally cultivated and introduced in temperate and tropical regions.

So far as known this plant does not persist away from cultivation.

2. *Amaranthus* L.

(*Acnida* L. [G, BB, P & S])

The reader is referred to Dr. Jonathan Sauer's paper, 'Revision of the dioecious amaranths' (Madroño 13: 5–46. 1955).

- a. Stout spines present at the base of most of the leaves 5. *A. SPINOSUS*
- a. No spines present on the plant b
- b. Male and female flowers in separate flowers on different plants (dioecious), the plants either all male (staminate) or all female (pistillate) c
- c. Calyx absent in pistillate flowers or at most consisting of 1 or 2 sepals d
- d. Sepals completely lacking in pistillate flowers; outer sepals of male flowers without heavy midribs, nearly equaling the inner sepals, blunt or acute; sepals of the male (staminate) flowers acute (short-pointed) or with short subulate tip 0.3 mm. or less; mature fruit splitting open irregularly or not splitting open, longer than the subtending bracts; bracts 1–1.5 mm. long, without heavy midribs 1. *A. TUBERCULATUS*
- d. 1 to 2 sepals present in pistillate flowers; outer sepals of male flowers with heavy midribs, longer than the inner sepals, cuspidate (abruptly tipped with a sharp or firm point); sepals of the male (staminate) flowers mostly long-pointed (long-acuminate) to a long slender tip; mature fruit circumscissile (splitting by a transverse circular line separating upper and lower section); bracts 1.5–2 mm. long, with heavy midribs 2. *A. TAMARISCINUS*
- c. Calyx present in pistillate flowers, consisting of 5 sepals e
- e. Bracts 4–6 mm. long, 2–3 times as long as the flowers, with scarious (thin) margins $\frac{1}{3}$ – $\frac{1}{2}$ or more of their length; outer sepals conspicuously longer than inner sepals; main leaves tapering to the tip, of an ovate or lance-oblong shape; longest outer sepals short- to long-pointed at tip 3. *A. PALMERI*
- e. Bracts 1.5–2.5 mm. long, usually shorter than or at most slightly longer than the flowers, with the scarious (thin) margins almost all the way to the tip; outer sepals scarcely or longer than inner sepals; main leaves rounded or blunt at tip, oblong-lanceolate to oblanceolate; sepals obtuse (blunt) or retuse (indented at tip) 4. *A. TORREYI*
- b. Male and female flowers in separate flowers on the same plant (monoecious) f
- f. Flowers in short clusters along the stem in the axils at the base of the leaves; plants usually growing low with spreading or sprawling branches or lying along the ground; stamens 2–3 g
- g. Seeds 1.3–1.7 mm. broad; the often purplish stems usually lying on the ground (prostrate); bracts ovate-oblong, more or less equal in length to the calyx and fruit or only slightly exceeding them 11. *A. GRAECIZANS*

876 *Amaranthus tuberculatus* (Water Hemp)

877 *Amaranthus tamariscinus* (Water Hemp)

878 *Amaranthus Palmeri*

- g. Seeds 0.7–1 mm. broad; the usually whitish stems more commonly erect with spreading to ascending branches; bracts subulate (narrow with a slender point), much longer (2–3 times) than the calyx and fruit 10. *A. ALBUS*
- f. Flowers mainly in long and slender simple or branched spikes or panicles at the ends of the stems and branches and also in the leaf axils; plants with mainly erect stems; stamens 5, or 3 in *A. Powellii* h
- h. Sepals of pistillate flowers 1.5–2.3 mm. long; main bracts of pistillate flowers equaling, somewhat longer than, or up to twice as long as the sepals, 2–3.5 mm. long, not rigid. i
- i. At least the outer sepals of the pistillate flowers acute, 1.5–2 mm. long; bracts of pistillate flowers green or tinged with red, (rarely red); calyx equal to or somewhat longer than the fruit; lateral (side) branches (spikes) of the inflorescence erect or spreading-ascending 7. *A. HYBRIDUS*
- i. All the sepals of the pistillate flowers blunt (obtuse) or rounded at tip, 1.5 mm. long; bracts of pistillate flowers red or purple, sometimes green; calyx shorter than the fruit; lateral (side) branches (spikes) of the inflorescence widely spreading. 6. *A. CAUDATUS*
- h. Sepals of pistillate flowers 3–4 mm. long; main bracts of pistillate flowers 2–3 times as long as the sepals, 5–9 mm. long, rigid j
- j. Sepals of pistillate flowers rounded or truncate (as if cut straight across) or emarginate (shallowly notched) at tip; stamens 5; lateral (side) branches of inflorescences 1–5 cm. long; abundant throughout Missouri. 8. *A. RETROFLEXUS*
- j. Sepals of pistillate flowers acute or short-pointed at tip; stamens 3; lateral (side) branches of inflorescences 4–12 cm. long; rarely found, known only from St. Louis County 9. *A. POWELLII*

Acnida tuberculata var. *subnuda* Wats. [P & S]
Acnida tuberculata var. *prostrata* (Uline & Bray)
Robinson [P & S]
Flowers August–October.

Occurs on sand bars and mud flats along the Missouri and Mississippi rivers, and along the larger streams and their oxbow lakes. Scattered in northern, central, eastern, and western Missouri; absent from the Ozark section.

Ranges from New York, Quebec, Ontario, Wis-

consin, to North Dakota, south to Alabama, Tennessee, Mississippi, Louisiana, Arkansas, Missouri, and Nebraska; introduced in New England.

The variations in leaf shape, habit of plant, and arrangement of the pistillate spikes are considered best treated under the one name.

This species is less common in the state than the next one, *A. tamariscinus*. This species is believed to have some association with causing hay fever, as is definitely the case in the next species, *A. tamariscinus*.

2. ***Amaranthus tamariscinus*** Nutt.
Water Hemp Map 877
Acnida tamariscina (Nutt.) Wood [G, BB, P & S]
Flowers July–October.

Occurs in moist alluvial soils of mud flats and on banks of streams, sloughs, oxbow lakes, and cultivated fields. Common along the larger streams in northern,

879 *Amaranthus Torreyi*880 *Amaranthus spinosus* (Thorny Amaranth)881 *Amaranthus caudatus* (Purple Amaranth)

central, western, and eastern Missouri; absent from most of the Ozark region.

Ranges from Indiana, Wisconsin, Iowa, Minnesota, North and South Dakota, and Idaho, south to Alabama, Tennessee, Mississippi, Louisiana, Texas, and New Mexico; introduced in the eastern states of Maine, Massachusetts, New Jersey, and Delaware.

This is much more common in Missouri than *A. tuberculatus*. In sections of its range where the species is abundant (parts of Oklahoma, Nebraska, Iowa, South Dakota, and Missouri), this species has been found to be important in causing cases of hay fever in late summer, contributing to 35 per cent of cases in some areas.

3. ***Amaranthus Palmeri* S. Wats.** Map 878
Flowers August–October.

Occurs in waste ground and along railroads. Known only from central and western Missouri in St. Louis (St. Louis, Rock Island R.R., south of Carrie Avenue, August 14, 1954, *Muehlenbach* 331), Jackson, and Jasper (waste ground along railway grade, Stockyard Switch, Joplin, August 10, 1949, *Palmer* 49748) counties.

Ranges from Oklahoma to California, south to Texas and Mexico; introduced in Kansas, Missouri, Illinois, Massachusetts, New York, Pennsylvania, and elsewhere in the East.

In part of its range, where abundant, this species is believed to be an important cause of hay fever.

4. ***Amaranthus Torreyi* (Gray) Benth.** Map 879
Amaranthus arenicola I. M. Johnston
Flowers late June–October.

Occurs in waste ground and along railroads. Known only from central Missouri in Jackson and St. Louis (St. Louis, Burlington R.R. north of E. Grand Ave., July 5, 1954, *Muehlenbach* 228) counties.

Ranges from Iowa to Colorado, south to Texas and New Mexico; introduced in Missouri, Illinois,

Michigan, Pennsylvania, New Jersey, D.C., and Virginia.

5. ***Amaranthus spinosus* L.** Map 880
Thorny Amaranth
Also called Careless Weed.
Flowers early June–October.

Occurs in waste and cultivated ground. Southern and central Missouri north to Pike, Monroe, Saline, Ray, and Clay counties; not recorded from northern Missouri, but doubtless of expected occurrence in that section.

Probably native of tropical America and naturalized in the United States from Florida to Texas, north to Maine, Ontario, and Minnesota; also naturalized in the Old World tropics.

In some tropical American countries the young leaves and shoots are cooked as a vegetable.

6. ***Amaranthus caudatus* L.** Purple Amaranth Map 881

Also called Love-Lies-Bleeding; Tassel Flower.

Amaranthus cruentus L. [G]

Amaranthus paniculatus L. [P & S]

Amaranthus hybridus in part [BB], not L.

Flowers August–October.

Cultivated as a garden annual, rarely escaping along roadsides, dumps, and waste ground in Missouri, where known from a few counties in the northern and central part of the state.

Probably native of tropical America; introduced into North America, where naturalized from Quebec and throughout most of the United States; also naturalized in the Old World.

This species does not appear to persist or maintain itself, so that one finds only an occasional waif here and there escaped from gardens. The differences between *A. caudatus* and *A. cruentus* do not appear to be distinct enough for separating them as species, and it seems preferable to keep all the red and purple forms

under one name. In Mexico the seeds of this plant are mashed up and mixed with water as a type of mush.

7. **Amaranthus hybridus** L. Green Amaranth

Map 882

Also known as Prince's Feather, Pigweed, Wild Beet, Careless Weed, Slender Pigweed.

Amaranthus hybridus var. *hypochondriacus* (L.) Robinson [P & S]

Flowers August–October.

Occurs as a weed in cultivated fields, pastures, farm lots, around dwellings, gardens, along railroads, and waste places. Throughout Missouri, and doubtless in every county, but only recorded from a relatively small number of counties.

Probably native of tropical America; naturalized in many parts of the Old World, and in the New World found throughout the temperate and tropical portions, in North America ranging from Quebec, Massachusetts, Ontario, and Michigan to Iowa, south throughout the United States.

The var. *hypochondriacus*, sometimes known as Prince's Feather, with usually copper-red or red-tinged inflorescences, is cultivated and escaped in St. Louis and Boone (city dump, Columbia, August 18, 1933, *Drouet* 983; ballast in East Highlands, Columbia, August 9, 1933, *Drouet* 921) counties, but is usually not considered varietally distinct.

Amaranthus hybridus makes a very palatable cooked vegetable and spinach substitute when the young plants or shoot tips are gathered. They can be eaten alone or mixed with *Chenopodium*, *Rumex*, *Lactuca*, and *Phytolacca*. The nutritious seeds can be made into a bread, for which purpose they were employed by some southwestern tribes of American Indians. Pigs are fond of eating this and the next species, accounting for one of the common names of the plant.

8. **Amaranthus retroflexus** L.

Rough Green Amaranth

Map 883

Also called Rough Green Pigweed, Careless Weed, Wild Beet.

Flowers July–October.

Occurs in cultivated fields, farm lots, along roadsides, railroads, waste places, gardens, and occasionally in dry open places on top of bluffs and prairies. Throughout Missouri; actual records are relatively

Plate no. 150. 1. *Amaranthus tuberculatus*, female plant, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden. 2. *Amaranthus Powellii*, $\times \frac{2}{5}$. 3. *Amaranthus spinosus*, $\times \frac{2}{5}$. 4. *Amaranthus graecizans*, $\times \frac{2}{5}$. 5. *Amaranthus retroflexus*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden.

882 *Amaranthus hybridus* (Green Amaranth)883 *Amaranthus retroflexus* (Rough Green Amaranth)884 *Amaranthus Powellii*

few, but doubtless to be found in most counties.

Native of tropical America; naturalized in North America and throughout the United States; naturalized also in many parts of the Old World.

As in the case of *A. hybridus*, the young plants of this species make an excellent cooked vegetable. Normally *A. retroflexus* is eaten by livestock without having any harmful effects, but some reported cases of poisoning, producing a bloated condition, have been attributed to the eating by cattle and horses of this or other plants containing a high percentage of stored nitrates, particularly where plants had been growing on a soil rich in fertilizer and nitrates or in years of drouth.

Late summer cases of hay fever are partly caused by this species in areas where it is abundant. The foliage in autumn may turn a brownish red.

9. ***Amaranthus Powellii* S. Wats.** Map 884
Flowers late June–October.

Occurs along railroads and waste ground, where known only from St. Louis County (St. Louis, Terminal R.R. Association between W. Florissant Ave. and Broadway, opposite Hussmann Refrigerator Co., August 28, 1955, *Muehlenbach* 726; Bremen Ave. freight yard of Terminal R.R. Association, July 4, 1958, *Muehlenbach* 1435).

Ranges from South Dakota to Oregon, south to Texas and California; introduced in Missouri, and from Maine to Pennsylvania.

10. ***Amaranthus albus* L.** Tumbleweed Map 885
Flowers July–October.

Occurs in cultivated and waste ground, along roadsides and railroads, sandy, gravelly, or muddy banks and flats along streams. Throughout Missouri.

Two variations are represented in Missouri material:

Plant glabrous (without hairs) . . . 10a. *A. ALBUS*
var. *ALBUS*

Plant finely hairy . . . 10b. *A. ALBUS* var. *PUBESCENS*

10a. ***Amaranthus albus* var. *albus*** Map 885
Amaranthus albus L. [G, BB]

Amaranthus graecizans of auth. [P & S], not L.

This is the commonly encountered variation in the state. Actually recorded from relatively few counties, but doubtless to be found in every county.

Ranges from southern Canada, south throughout the United States; introduced into Europe.

10b. ***Amaranthus albus* var. *pubescens*** (Uline & Bray) Fern. Map 885

Known from Jackson and Barton (open ground along roadside near river, near Bushnell, July 8, 1952, *Palmer* 54468; sandy open ground along Horse Creek, 5 mi. northeast of Milford, August 23, 1952, *Palmer* 54893) counties in western Missouri.

Ranges from Colorado, Nevada, and New Mexico, east to Missouri.

This is a very common tumbleweed. After maturing, the plants, like Russian Thistle (*Salsola Kali* var. *tenuifolia*), are blown around, accumulating along fence rows, roadsides, and ditches, and becoming a nuisance in road clearance or even injurious to fences.

11. ***Amaranthus graecizans* L.** Tumbleweed Map 886

Also called Prostrate Amaranth, Spreading Pigweed.

Amaranthus blitoides S. Wats. [P & S]
Flowers early June–October.

PLATE NO. 151

885 • *Amaranthus albus* var. *albus* (Tumbleweed)
885 □ *Amaranthus albus* var. *pubescens*

886 *Amaranthus graecizans* (Tumbleweed)

887 *Tidestromia lanuginosa*

Occurs in waste and cultivated ground, along roadsides, railroads, and sandy or gravelly places along streams. Scattered throughout Missouri, although actually recorded from but few counties, but doubtless to be found in most of them.

Native of the western states from North Dakota to

British Columbia, south to Texas and California; established throughout most of the eastern United States and northeast to Quebec.

This species is more prostrate in habit than *A. albus*. It is a good source of green food for poultry and hogs.

3. *Tidestromia* Standl.

***Tidestromia lanuginosa* (Nutt.) Standl**

Map 887

Cladothrix lanuginosa Nutt. [P & S]

Flowers July–October.

Occurs in waste ground and along railroads, where known only from west-central Missouri in Jackson County (Kansas City, September 26, 1921, *Bush* 9695, 9695A, 9695B; Courtney, July 16, 1916, *Bush* 8523; September 10, 1918, *Bush* 8783, 8783A; August 1,

1918, *Bush* 8161).

Ranges from South Dakota to Colorado and Nevada, south to Texas and Mexico; introduced in Missouri and Illinois.

This prostrate or sprawling annual with many forking stems is covered with a dense coating of gray stellate pubescence. It somewhat resembles *Glinus lotoides* in habit of growth and appearance of leaves and flowers.

4. *Iresine* P. Br. Bloodleaf

***Iresine rhizomatosa* Standl. Bloodleaf** Map 888

Also known as Juba's Bush.

Iresine paniculata (L.) Ktze. [P & S]

Flowers August–October.

Occurs in low wet woods and thickets near streams. Southern and central Missouri, north to St. Louis, Franklin, Gasconade, Osage, Camden, Benton, St. Clair, and Vernon counties.

Ranges from Alabama to Texas, north to Virginia and Maryland, Indiana, Illinois, Missouri, and Kansas.

Although the flowers themselves are quite minute, the silvery-white color of the bracts and calyx makes the elongated, pyramidal panicle quite showy in the deep shade in which the plants grow.

5. *Froelichia* Moench. Cottonweed

Woolly fruiting calyx with toothed or irregular margins (remove the wool to see clearly); flower spikes 10–13 mm. thick; leaves elliptic-lanceolate or oblanceolate; larger leaf-blades 5–25 mm. broad; stem stout, up to 7 mm. thick and up to 2 m. tall, either unbranched or with a few erect branches . . .

1. *F. FLORIDANA* var. *CAMPESTRIS*

Woolly fruiting calyx with slender spine-like, nearly distinct projections on the margins (remove the

888 *Iresine rhizomatosa* (Bloodleaf)

889 *Froelichia floridana* var. *campestris* (Cottonweed)

890 *Froelichia gracilis* (Cottonweed)

wool to see clearly); flower spikes 7–8 mm. thick; leaves linear to narrowly lanceolate; larger leaf-blades mainly 3–9 mm. (rarely up to 15 mm.) broad; stem slender, 1–2 mm. thick, 1.5–4.5 dm. (up to 6 dm.) tall, commonly with spreading branches at the base 2. *F. GRACILIS*

1. ***Froelichia floridana*** (Nutt.) Moq. var. ***campestris*** (Small) Fern. Cottonweed Map 889
Froelichia floridana in part [BB, P & S in part]
Flowers May–September.

Occurs in sandy open ground and along railroads, frequently on sand and gravel bars along streams. Eastern Missouri mainly, west in central Missouri to Jackson County and in southern Missouri to Laclede and St. Clair counties.

Ranges from Indiana to Minnesota and South Dakota, south to Arkansas, Oklahoma, Texas, and New Mexico; introduced in Delaware and Maryland.

This species is much more robust and luxuriant-looking than the next, *F. gracilis*. From typical var. *floridana* of the southeastern states, var. *campestris* differs in the leaves rounded at the tip and broadest above the middle.

2. ***Froelichia gracilis*** (Hook.) Moq. Cottonweed Map 890
Flowers May–September.

Occurs in sandy open ground and along railroads, and on sand and gravel bars along streams. Southern and central Missouri north to Marion and Livingston counties; frequent along some of the sandy and gravelly flats bordering Ozark streams.

Ranges from Indiana to Iowa and Colorado, south to Arkansas, Texas, New Mexico, and Mexico; introduced eastward to New York, New Jersey, and Virginia.

A collection by E. J. Palmer from Jasper County (Palmer 56454 from Joplin, August 11, 1953) is somewhat intermediate between *F. gracilis* and *F. floridana* var. *campestris*, with the fruiting calyx characteristic of *F. gracilis* but the larger and usual form of the leaves of *F. floridana* var. *campestris*; it may be indicative of hybrid origin.

Fam. **NYCTAGINACEAE** (Four-o'clock Family)

Flowers arising from a green calyx-like 5-lobed involucre; flowers conspicuous, the pink to purple portion (the calyx) 7–10 mm. long 1. *MIRABILIS*
Flowers not arising from a lobed involucre, but accompanied at their base by minute distinct bracts; flowers minute, the pink to white portion (calyx) 1–1.5 mm. long 2. *BOERHAAVIA*

1. ***Mirabilis*** L. Four-o'clock

- a. Leaves (except the uppermost) with definite petioles (stalk) 10–30 mm. long; main leaf-blades ovate or triangular-ovate, broadest at the base 1. *M. NYCTAGINEA*
a. Leaves all sessile (without stalks) or with a very short petiole; leaf-blades linear, lanceolate, or oblong, nearly the same width throughout or only slightly broader at the base b
b. Leaves linear, usually at most 5 mm. wide, 15–30 times as long as wide; stems glabrous (without any hairs) below the inflorescence; angles of fruit smooth 4. *M. LINEARIS*
b. Leaves narrowly lanceolate or narrowly oblong, the main ones usually 10–40 mm. wide (or

891 *Mirabilis nyctaginea* (Wild Four o'clock)892 *Mirabilis hirsuta*893 *Mirabilis albida*

rarely 4–9 mm. wide), 2–12 times as long as wide; stems either noticeably hairy with spreading hairs or inconspicuously hairy with 2 lines of short hairs.

c. Stem noticeably hairy at least in the lower part with hairs 1–2.5 mm. long; leaf-blades 1–4 times as long as wide, broadly wedge-shaped at base; angles of fruit smooth 2. *M. HIRSUTA*

c. Stem inconspicuously hairy with 2 lines of short incurved hairs about 0.5 mm. long; leaf-blades 4–12 times as long as wide, tapering at base; angles of fruit roughened with little projections (tuberculate) 3. *M. ALBIDA*

1. ***Mirabilis nyctaginea*** (Michx.) Mac M.

Wild Four-o'clock Map 891

Also known as Heart-leaved Umbrella-wort.

Oxybaphus nyctagineus (Michx.) Sweet [P & S];

Oxybaphus floribundus Choisy. [P & S]

Flowers May–October.

Occurs mostly along railroad tracks, also in open ground, prairies, and waste places. Throughout Missouri, in most counties.

Ranges from Wisconsin and Manitoba to Montana and Colorado, south to Alabama, Louisiana, and Texas; introduced east to Massachusetts and Virginia.

2. ***Mirabilis hirsuta*** (Pursh) Mac M. Map 892

Oxybaphus hirsutus (Pursh) Sweet [P & S]

Oxybaphus hirsutus var. *integrifolius* Choisy. [P & S]

Flowers May–October.

Occurs in dry open ground, glades, and along roadsides. Scattered in western Missouri east to Grundy, Boone, Dallas, and Ozark counties.

Ranges from Wisconsin to Saskatchewan and Wyoming, south to Missouri, Oklahoma, Texas, New Mexico, and Arizona; introduced eastward to New England.

3. ***Mirabilis albida*** (Walt.) Heimerl Map 893

Oxybaphus albidus (Walt.) Sweet [P & S]

Allionia decumbens Nutt. [Rydb.]

Allionia bracteata Rydb. [Rydb.]

Flowers May–October.

Occurs along edges of bluffs, limestone glades, prairies, and open ground, rarely in rocky open woods. Western, southern, and central Missouri, northeast to Ralls County; absent from the northeastern sector of the state.

Ranges from Georgia to Texas, north to South Carolina, Tennessee, Iowa, and Kansas; rarely introduced northeastward.

This species varies somewhat in width of leaves and amount of pubescence on the stems. The stems are silvery-gray or glaucous and have hairy lines, but appear glabrous.

4. ***Mirabilis linearis*** (Pursh) Heimerl Map 894

Oxybaphus linearis (Pursh) Robinson [P & S]

Flowers May–October.

Occurs on rocky prairies, limestone glades, edges of limestone escarpments, and open wooded rocky limestone hills. Scattered and rare in western Missouri in Jackson, Jasper, Lawrence, and Miller counties.

Ranges from Minnesota to Montana, south to Missouri, Oklahoma, Arizona, and Mexico; rarely introduced northeastward to New England.

Many narrowly lanceolate-leaved collections of *M. albida* have been misidentified as this species. Actually, *M. linearis* is the rarest of the species in Missouri.

Plate no. 152. 1. *Mirabilis nyctaginea*, $\times \frac{2}{7}$. 2. *Mirabilis hirsuta*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 3. *Mirabilis albida*, $\times \frac{2}{7}$; Details from Small, The New York Botanical Garden. 4. *Boerhaavia erecta*, $\times \frac{2}{7}$; a. 896 *Phytolacca americana* (Pokeweed)

2. *Boerhaavia* L.

***Boerhaavia erecta* L.**

Map 895

Boerhaavia erecta f. *subpunctata* Heimerl
Flowers July–October.

Occurs along railroads. Known only from St. Louis County (St. Louis, Bremen Ave. freight yard of the Terminal Railroad Assoc., September 1, 1958, *Muehlenbach 1481*).

Native of tropical America, ranging from South

to Central America, the West Indies, and Mexico, and extending in the southern United States from Florida to Texas and Arizona, north to South Carolina, Missouri, and Arkansas.

This plant has more or less procumbent stems. The leaves are cooked and eaten like spinach in some parts of the American tropics.

Fam. **PHYTOLACCACEAE** (Pokeweed Family)

***Phytolacca americana* L.** Pokeweed

Map 896

Known also as Poke.
Flowers late May–October.

Occurs in rich soils in waste ground, farm lots, about dwellings, fields, along roadsides and railroads, thickets, and borders of woods. Throughout the state and doubtless in every county.

Ranges from Quebec, Maine, New York, and Ontario to Minnesota, south to Florida and Texas. Also in Mexico; introduced in Europe.

The roots and purple rind of the fully grown stem are poisonous, but the tender young leaves and shoots make a tasty cooked vegetable, prepared alone or mixed with other wild greens. Brought indoors before winter, the root, placed in earth in a cellar, can be forced into

sending up succulent sprouts, which are cut when young and serve as an asparagus substitute during the winter and early spring months. The root has been used in medicine for treatment of skin diseases, and for garget (swelling of the throat) in cattle. The berries are actually not poisonous, as sometimes stated, but the seeds are suspected of having poisonous properties as children have been poisoned after eating the berries. The berries are eaten by birds in great quantity. The purple juice of the berries is used for coloring foods, such as frostings and candies, and beverages. The dried berries, cut up and put into whiskey, have been used as a remedy for rheumatism. The juice of the fresh berries is also used as a red ink.

Fam. **AIZOACEAE** (Carpet-weed Family)

The genus *Geocarpon*, previously placed in this family, has been transferred to Fam. **Caryophyllaceae** (Bull. Torr. Club 77: 268–73. 1950), and is to be found in the present flora in its newly placed position.

- a. Leaves opposite, in more or less unequal pairs 1. **TRIANTHEMA**
a. Leaves in whorls (circles) of 3–8, unequal in size and shape b

- b. Plants glabrous (without hairs); leaves narrow, spatulate, the larger ones usually 3-5 (rarely to 10) mm. wide and 4-8 times as long as broad; flowers on slender stalks (pedicels) 2. *MOLLUGO*
- b. Plants hairy with star-shaped hairs (stellate-pubescent); leaves round-obovate, the larger ones 8-20 mm. (rarely only 5) wide and $1\frac{1}{2}$ -2 times as long as broad; flowers sessile (without stalks) 3. *GLINUS*

1. *Trianthema* L. Sea Purslane

Trianthema Portulacastrum L. Sea Purslane

Map 897

Flowers May-October.

Occurs in waste ground, where introduced. Known only from west-central and southwestern Missouri in Jackson and Jasper (rich waste ground along Stock-

yard Switch, Joplin, September 26, 1949, *Palmer 49835*) counties.

Throughout the tropical regions of both the Old and New World; in the United States ranging from Florida to Texas and California, north to New Jersey, Missouri and Oklahoma.

2. *Mollugo* L. Carpet-weed

Mollugo verticillata L. Carpet-weed

Map 898

Flowers May-November.

Occurs as a weed in waste and cultivated ground and along railroads. Throughout Missouri and doubtless in every county.

Found in the Old World and in temperate and tropical North America, Central and South America and the West Indies; naturalized in North America from Florida to Texas, north to Nova Scotia, Quebec, Ontario, and Washington.

3. *Glinus* L.

Glinus lotoides L.

Map 899

Flowers July-September.

Occurs in wet muddy alluvial ground along rivers and oxbow lakes of stream meanders. Known only from western Missouri in Jackson, Lafayette, Henry, and Vernon counties.

Native of tropical Africa and southern Europe; introduced into the United States, where ranging from Louisiana to California, north to Missouri and Oklahoma.

The stems are widely spreading, procumbent to ascending and repeatedly forked. With their short hairiness of star-shaped hairs and leaf-shape, the plants closely resemble the amaranthaceous *Tidestromia lanuginosa*, from which they are best distinguished by the many ovules in a 3-5-celled ovary in *Glinus* as opposed to the 1-celled ovary with 1 ovule in *Tidestromia*. In both genera the calyx consists of 5 distinct sepals or nearly so.

900 *Portulaca oleracea* (Purslane)

901 *Portulaca neglecta* (Purslane)

902 *Portulaca retusa* (Purslane)

Fam. **PORTULACACEAE** (Purslane Family)

- a. Only 2 leaves generally present on each flowering stem; leaf-blades 4–15 cm. long 2. CLAYTONIA
- a. Several to many leaves present with each flowering stem; leaf-blades 0.6–5 cm. long b
- b. Leaves scattered along the flowering stem from near base to near tip of stem; flowers sessile (without stalks) or nearly so 1. PORTULACA
- b. Leaves in a tuft or rosette at the base of the plant; flowers stalked, supported by a long, erect naked stem (scape) which is much longer than the leaves 3. TALINUM

1. **Portulaca** L. Purslane

- a. Plants completely glabrous (without hairs); leaves flat, broadest in the upper half, the larger ones 8–16 mm. wide; petals yellow b
- b. Calyx-lobes obtuse; seeds covered with rather sharp-pointed conical projections (tubercles); leaves often retuse (with a shallow notch at summit) 3. *P. RETUSA*
- b. Calyx-lobes pointed; seeds covered with blunt or rounded projections (tubercles); leaves commonly rounded or truncate (as if cut straight across) at summit, rarely retuse (with a shallow notch at tip) c
- c. Commonly found; stems lying on ground (prostrate); main leaves 1–3 cm. long; stamens 7–12 1. *P. OLERACEA*
- c. Rare, western Mo. plant; stems ascending; main leaves 2.5–5 cm. long; stamens 12–18 2. *P. NEGLECTA*
- a. Plants with hairy tufts in the axils of the leaves; leaves cylindrical or nearly so with curved or rounded sides, about the same width throughout, about 2 mm. wide; petals red, rose-purple, pink, white, orange, or yellow d
- d. Flowers red or rose-purple, less than 1 cm. wide; petals 5–7.5 mm. long; stamens 10–30; native species of rocky limestone, sandstone, or chert glades 4. *P. MUNDULA*
- d. Flowers red, orange, white, or rich yellow, 2–4 cm. wide; petals 15–30 mm. long; stamens about 40; not native, escaped from gardens in waste ground and along railroads 5. *P. GRANDIFLORA*

1. **Portulaca oleracea** L. Purslane Map 900
Also called Pusley or Pursley.
Flowers June–November.

Occurs in cultivated and waste ground, rocky escarpments along bluffs, and open places. Scattered throughout Missouri, and doubtless in every county, although represented by relatively few county collections.

Native of Europe; introduced in North America, where found from southern Canada south throughout the United States. Also naturalized in temperate and tropical regions of the New and Old World.

The plant may be eaten in various ways, the stems and leaves either cooked as a vegetable alone or in combination with turnip tops or mustard greens or

with bread-crumbs and eggs, or used as a fresh green in salad form, or pickled. Some of the Indians of the southwestern United States are reported using the seeds in a kind of bread or mush. The plants are one of the favorite hog foods. They also help in building up soils.

2. **Portulaca neglecta** Mack. & Bush
Purslane Map 901
Flowers July–September.

Occurs on limestone glades, prairies, and rich alluvial bottoms. Western Missouri, where known from Caldwell, Jackson, Cass, Johnson, and Jasper counties.

Ranges from Missouri to Arkansas.

900 *Portulaca oleracea* (Purslane)

901 *Portulaca neglecta* (Purslane)

902 *Portulaca retusa* (Purslane)

Flowers June–November.

Occurs in cultivated and waste ground, rocky escarpments along bluffs, and open places. Scattered throughout Missouri, and doubtless in every county, although represented by relatively few county collections.

Native of Europe; introduced in North America, where found from southern Canada south throughout the United States. Also naturalized in temperate and tropical regions of the New and Old World.

The plant may be eaten in various ways, the stems and leaves either cooked as a vegetable alone or in combination with turnip tops or mustard greens or

with bread-crumbs and eggs, or used as a fresh green in salad form, or pickled. Some of the Indians of the southwestern United States are reported using the seeds in a kind of bread or mush. The plants are one of the favorite hog foods. They also help in building up soils.

2. **Portulaca neglecta** Mack. & Bush
Purslane Map 901
Flowers July–September.

Occurs on limestone glades, prairies, and rich alluvial bottoms. Western Missouri, where known from Caldwell, Jackson, Cass, Johnson, and Jasper counties.

Ranges from Missouri to Arkansas.

903 *Portulaca mundula*904 *Portulaca grandiflora* (Portulaca)905 • *Claytonia virginica* f. *virginica* (Spring Beauty)
905 □ *Claytonia virginica* f. *robusta*

Gleason (*New Ill. Fl.* 2: 114. 1952) has indicated that this may be only a luxuriant form of *P. oleracea*, and considers it as of doubtful specific rank, and Shinnars (*Spring Flora*, p. 137) has relegated it to synonymy under *P. oleracea*. However, until more detailed field investigations can be carried out in the future, the species is being retained as such, based upon the characters as given in the key.

3. ***Portulaca retusa*** Engelm. Purslane Map 902
Flowers July–September.

Occurs on limestone and chert glades, where known only from southwestern Missouri in Jasper and Newton (chert barrens, near Reding's Mill, October 7, 1927, *Palmer 33158*) counties.

Ranges from Missouri to Utah, south to Arkansas, Texas, and Arizona.

4. ***Portulaca mundula*** Johnston Purslane Map 903

Portulaca parvula of auth. [G, BB, P & S, Steyerlm.], not Gray

Flowers last of May–October.

Occurs on sandstone, chert, and limestone glades and edges of rocky exposed bluffs and escarpments in western Missouri south of the Missouri River from Jackson County south to Newton County, east to Polk and Greene counties, and exceptionally introduced along railroads in east-central Missouri in St. Louis County (St. Louis, along Mo.-Kan.-Tex. R.R., Baden Freight Yard, October 7, 1956, *Muehlenbach 11116*).

Ranges from Missouri and Kansas to Oklahoma, Texas, and New Mexico.

On limestone glades and outcrops on the edge of

southwest-facing limestone bluffs this species is often associated with *Sphaeralcea angusta*, *Mentzelia oligosperma*, *Ophioglossum Engelmanni*, and other calcareous-inhabiting types. On sandstone exposures and glades it occurs with a different selection of associates, such as *Sedum Nuttallianum*, *Oenothera linifolia*, *Linaria canadensis* var. *texana*, *Krigia virginica*, *Talinum parviflorum*, *Selaginella rupestris*, and *Crotonopsis elliptica*, species all favoring acid soils.

Missouri material has been confused previously with true *P. parvula* Gray. Dr. I. M. Johnston (*Jour. Arn. Arb.* 29: 195–96. 1948) has shown that the Missouri specimens constitute an undescribed species, characterized by the red-purplish or purple-red obovate petals often as much as 6–7.5 mm. long, 3–4.5 mm. wide, retuse at the summit, by the lower part of the capsule 2.5–3.5 mm. in diameter, by the shortly stipitate capsule, by the mature capsule having the upper part smooth and hemispherical with hairy calyx and stamens cohering, by the 10–15 (rarely 30) stamens, and by the black stellate-tuberculate seeds 0.3–0.5 mm. in diameter.

Contrasted with *P. mundula*, typical *P. parvula* Gray of Oklahoma, Texas, Arizona, and New Mexico has yellow, orange, or bronzy petals 2–2.5 mm. long, small, conspicuously stipitate fruit, which, after dehiscence and shedding of the seeds, is only 1.5–2 mm. in diameter at the saucer-shaped base. The well-developed stipe is 1–1.5 mm. long, and the seeds are 3–3.5 mm. long, at first brownish, becoming black when mature and covered with minute, crowded, flattened stellate surface markings.

5. ***Portulaca grandiflora*** Hook.

Portulaca, Rose Moss

Map 904

PLATE NO. 154

906 *Talinum parviflorum* (Fame Flower)907 *Talinum calycinum* (Fame Flower)908 *Scleranthus annuus* (Knapel)

Flowers July–September.

Commonly cultivated, but rarely escaping along roadsides and along railroads. Known only from Boone (roadside, Columbia, July, 1903, Daniels) and

St. Louis (St. Louis, Mo. Pac. R.R. under the loading ramp of the Cornel Seed Co., August 23, 1958, *Muehlenbach 1468*).

Native of Argentina.

2. *Claytonia* L. Spring Beauty

***Claytonia virginica* L.** Spring Beauty Map 905

Flowers February–May.

Occurs commonly in dry upland open woods on level ground or hillsides, moist alluvial wooded or open valleys, prairies, and rocky ledges. Throughout Missouri.

Ranges from Nova Scotia, Quebec, and Ontario to Minnesota, south to Georgia, Alabama, Mississippi, Louisiana, and Texas.

Two variations are represented in Missouri material:

- Leaves 2–10 mm. wide, linear or linear-oblongate a. *C. VIRGINICA* f. *VIRGINICA*
 Leaves 10–33 mm. wide, rather broad in the middle, lanceolate or elliptical b. *C. VIRGINICA* f. *ROBUSTA*

a. ***Claytonia virginica* f. *virginica*** Map 905

Claytonia virginica L. [G, BB, P & S, Steyerl.]

This is the commoner form found doubtless in every county of the state.

b. ***Claytonia virginica* f. *robusta*** (Somes)

Palmer & Steyerl. Map 905

Scattered throughout the state and not uncommon. This form has been confused at various times with the more eastern and northern species, *C. caroliniana* Michx., of which no authentic specimens have been found in the state.

The young plants of Spring Beauty, in regions of abundance, may be eaten as a cooked vegetable, while the thick, round, underground corms, when boiled in salted water, resemble the taste of chestnuts.

3. *Talinum* Adans. Fame Flower, Rock Pink

Petals 3–7 mm. long, pale or dull pink; stamens 4–8 (mainly 5–6); capsules 3–5 mm. high . . . 1. *T. PARVIFLORUM*
 Petals 10–15 mm. long, deep rose-pink or rose-red; stamens 25–45; capsules 6–8 mm. high . . . 2. *T. CALYCINUM*

1. ***Talinum parviflorum* Nutt.**

Fame Flower, Rock Pink

Map 906

Flowers May–August.

Occurs on more or less level sandstone and chert glades and rocky outcrops above bluffs. Southern and central Missouri, in the Ozark and unglaciated prairie sections, north to St. Louis, St. Charles, Warren, Montgomery, Cole, Johnson, and Bates counties; absent from the southeastern lowland area.

Ranges from Minnesota to South Dakota and Colorado, south to Missouri, Arkansas, Texas, Arizona, and Mexico.

This species has shorter leaves and shorter, more delicate peduncles than the following one.

2. ***Talinum calycinum* Engelm.**

Fame Flower, Rock Pink

Map 907

Flowers May–August.

Occurs on sandstone, chert, granite, or limestone glades and outcrops of exposed bluff escarpments on more or less level rocks. Known only from the Ozark and unglaciated prairie sections of southern and central Missouri, north to Lincoln, Montgomery, Callaway, Cooper, Benton, St. Clair, and Vernon counties, and locally in Jackson County.

Ranges from Missouri, Kansas, and Oklahoma to Arkansas and Texas.

This species does well in rock gardens if provided with sufficient sunlight and drainage. It does not

appear particular as to the type of rock on which it grows. The author has had plants which have maintained and seeded themselves during the past fifteen years in northern Illinois. The flowers open around noon and close after a few hours. Plants often occur in abundance, and in some places, where they occur on sandstone, their bright rose-red flowers mingle colorfully with the yellow flowers and silvery green foliage of *Sedum Nuttallianum*, the delicate white sprays of *Arenaria patula*, and the purple flowers of *Specularia leptocarpa*.

Fam. **CARYOPHYLLACEAE** (Pink Family)

- a. Transparent papery-like stipules at the base of the leaves *b*
- b. Leaves in 2's opposite one another, elliptic to oblanceolate, 0.5-3 cm. long; petals normally absent; native plants of woodland and rocky open places 3. PARONYCHIA
- b. Leaves appearing in whorls of 6-8, filiform, 2-5 cm. long; petals present, white; introduced plant of waste and cultivated ground and along railroads 4. SPERGULA
- a. No stipules at the base of the leaves *c*
- c. Calyx of separate sepals, these not united at the base. *d*
- d. Inflorescence umbellate, the 3-8 flowers on slender stalks (pedicels) of about equal length and arising at the tip of the main flower stalk (peduncle) 9. HOLOSTEUM
- d. Inflorescence not as above, the flowers arranged otherwise *e*
- e. Leaves all thread- or hair-like, 0.5-1 mm. broad *f*
- f. Styles normally 3; stems erect; petals 5, conspicuous, about 2 times the length of the sepals; sepals 5 6. ARENARIA
- f. Styles 4 or 5; stems mostly ascending or spreading; petals 0 or 4-5, inconspicuous, shorter, equaling, or slightly longer than sepals; sepals 4 or 5 5. SAGINA
- e. Leaves broader. *g*
- g. Styles 5; stems either with noticeable spreading hairs or these not occurring in definite lines; fruit much longer than broad, cylindrical, with usually 10 hair-like teeth at the summit 8. CERASTIUM
- g. Styles 3; stems either glabrous (without hairs) or with very short inconspicuous hairs occurring in definite lines or pressed close to the stem; fruit ovoid or ellipsoid, with no teeth at summit or less than 10 teeth. *h*
- h. The white petals without a notch or at most with only a shallow notch at the tip 6. ARENARIA
- h. The white petals deeply notched or split nearly halfway or more to the base 7. STELLARIA
- c. Calyx with the sepals united into a short or long tube *i*
- i. Flowers all green, petals normally absent; calyx 3-5.5 mm. long *j*
- j. Stems 1-4 cm. tall or long, more or less erect; larger leaves about 5 mm. long, narrowly oblong or ovate-oblong, obtuse or blunt at tip; style none; stigmas 3; fruit many-seeded 2. GEOCARPON
- j. Stems up to 15 cm. tall or long, sometimes longer, the main part spreading or reclining; larger leaves 5-15 mm. long, thread- or hair-like, slender-pointed at tip; styles 2; fruit 1-seeded. 1. SCLERANTHUS
- i. Flowers with green, whitish, or pink calyx and white, rose, pink, or purple petals with petals normally present (absent in *Silene antirrhina* f. *apetala*); calyx 5-25 mm. long *k*
- k. 1-3 pairs of scales or leaf-like bracts are present at base of calyx; calyx-tube 30-40-nerved 14. DIANTHUS
- k. No scales or leaf-like bracts at base of calyx; calyx-tube faintly nerved or with 5-10-20 nerves (in species found in Missouri) *l*
- l. The elongated calyx-lobes longer than and extending beyond the purple-rose petals; calyx-lobes longer than the calyx-tube 10. AGROSTEMMA
- l. The calyx-lobes shorter than the petals or not extending beyond them; calyx-lobes much shorter than the calyx-tube, less than half as long as the tube. *m*

- m. Some or all flowers male (staminate) or female (pistillate), the sexes of the flowers usually separated on different plants (dioecious), or sometimes mixed with both unisexual and bisexual or perfect flowers (polygamo-dioecious) 11. *LYCHNIS*
- m. Most of the flowers perfect with both stamens and pistils in the same flower. n
- n. Styles 5; each of the 5 valves of the capsule with 2 teeth at the summit 11. *LYCHNIS*
- n. Styles 2 or 3; capsule with 3, 4, or 6 teeth at the summit 0
- o. Styles 2; capsule with 4 teeth at the summit, 4-valved; calyx scarcely nerved or 5-nerved 13. *SAPONARIA*
- o. Styles 3; capsule with 3 or 6 teeth at the summit, 3- or 6-valved; calyx 5-10- or 20-nerved 12. *SILENE*

1. *Scleranthus* L. Knewel

***Scleranthus annuus* L.** Knewel

Map 908

Mohlenbrock 86081).

Flowers March–October.

Occurs in moist depressions of upland sandstone glades, where known only from Greene County, southwestern Missouri (on northeast side of railroad tracks and highway 123, 0.2 mi. northwest of crossroad, and 1 mi. north of junction of road AC with highway 123, T30N, R23W, SE $\frac{1}{4}$ of SE $\frac{1}{4}$ sect. 8, 1 mi. [by air] southwest of Cave Spring, 5 mi. southeast of Walnut Grove, May 3, 1958, *Steyermark*, *Voigt*, and

Native of Europe; introduced into North America, where ranging from Quebec and Ontario to Minnesota, south to Florida, Mississippi, and Missouri, and on the Pacific Coast.

This annual was found growing in a wild environment, associated with *Geocarpon minimum*, *Saxifraga texana*, and *Isoetes Butleri*. The spreading stems with subulate leaves superficially resemble *Polypleurum procumbens* of the Loganiaceae.

2. *Geocarpon* Mackenzie

***Geocarpon minimum* Mackenzie**

Map 909

Flowers early April–May.

Occurs on upland sandstone glades in moist depressions where a small trickle of drainage seeps through or near the plant. Known only from the unglaciated prairie section of southwestern Missouri, in Jasper, Greene, Polk, and St. Clair counties.

Known only from southwestern Missouri and southeastern Arkansas (Drew and Bradley counties).

Until 1957 this plant was thought to be the rarest one in Missouri, and one of the rarest in the United States, having been known only from the originally collected locality north of Alba in Jasper County, southwestern Missouri. The genus was described in 1914 by Mackenzie (*Torrey* 14: 67–68) from specimens collected by E. J. Palmer, and was known to occur nowhere else in the world. In 1957 the present author found a second station in St. Clair County, 57 miles by air northeast of the original station. In 1958, accompanied by Drs. Voigt and Mohlenbrock

of Southern Illinois University, two new stations were found in Polk and Greene counties, and during the same spring of 1958 Dr. Dwight M. Moore of Arkansas Agricultural and Mechanical College collected the plant in Drew and Bradley counties of southeastern Arkansas for the first occurrence of the genus and species outside of Missouri. There is every reason to suppose that many more stations will be found on sandstone exposures in the unglaciated section of southwestern Missouri and perhaps from other states adjacent to Missouri.

The plants are often dull wine-purplish throughout or at maturity may turn an inconspicuous dull gray-green color. The perianth is pale green with the lower part frequently tinged with wine purplish color. The plant is quite diminutive and possesses a succulent aspect. For further details the reader is referred to Bull. Torr. Club 77: 268–73. 1950; Bull. Torr. Club 85: 124–27. 1958.

PLATE NO. 155

909 *Geocarpon minimum*910 *Paronychia canadensis* (Forked Chickweed)911 • *Paronychia fastigiata* var. *fastigiata* (Forked Chickweed)
911 □ *Paronychia fastigiata* var. *paleacea*

3. *Paronychia* Mill. Whitlow, Forked Chickweed

This genus is sometimes placed in a separate family, *Illecebraceae* [P & S, Steyerl.], but in the present treatment this family is combined with the *Caryophyllaceae*.

Stem glabrous (without hairs); calyx 1–1.5 mm. long with flat non-ribbed sepals; sepals shorter than the mature fruit, blunt at tip 1. *P. CANADENSIS*

Stem or branches minutely hairy; calyx 2–3 mm. long with ribs or strong nerves on the sepals; sepals usually as long as or longer than the mature fruit, with a minute pointed tip. 2. *P. FASTIGIATA*

1. *Paronychia canadensis* (L.) Wood

Forked Chickweed

Map 910

Anychia canadensis (L.) BSP. [P & S]

Flowers late May–October.

Occurs in dry open woods and shaded ground. Common throughout Missouri; apparently absent only from the lowland section of southeastern Missouri.

Ranges from New Hampshire to Ontario and Minnesota, south to Georgia, Alabama, Tennessee, Arkansas, and Kansas.

2. *Paronychia fastigiata* (Raf.) Fern.

Forked Chickweed

Map 911

Flowers late May–October.

Occurs in dry open woods, rocky open woods, and sandstone, chert, or granite glades, mostly in acid soils.

Two variations are encountered in Missouri material:

The small, thin, transparent stipular bracts accompanying the flowers are mainly shorter than or at most equal to the calyx . . . 2a. *P. FASTIGIATA*

VAR. *FASTIGIATA*

The small, thin, transparent stipular bracts accompanying the flowers are either equal to or

longer than the calyx 2b. *P. FASTIGIATA*
var. *PALEACEA*

2a. *Paronychia fastigiata* var. *fastigiata*

Map 911

Paronychia fastigiata (Raf.) Fern. [G]

Anychia polygonoides Raf. in part [P & S]

Nearly throughout Missouri; absent only from the counties of extreme northwestern Missouri. This is the commoner of the two variations in the state.

Ranges from Massachusetts to Minnesota, south to Florida and Texas.

2b. *Paronychia fastigiata* var. *paleacea* Fern.

Map 911

Anychia polygonoides in part [of P & S], not Raf.

Scattered throughout the state, but less common than var. *fastigiata*.

These variations intergrade and are often placed in one or the other rather arbitrarily. Usually plants of the var. *paleacea* are greenish and are found in less exposed situations, whereas in var. *fastigiata* the plants are copper-reddish or brick-colored, have more crowded flowers, and occur in more exposed or drier and sunnier situations, as pointed out by Deam (*Fl. Ind.* p. 443).

PLATE NO. 156

912 *Spergula arvensis* var. *arvensis*

913 *Sagina decumbens* (Pearlwort)

914 • *Arenaria serpyllifolia* var. *serpyllifolia* (Thyme-leaved Sandwort)

914 □ *Arenaria serpyllifolia* var. *tenuior*

4. *Spergula* L. Spurrey

Spergula arvensis* L. var. *arvensis

Corn Spurrey

Map 912

Spergula arvensis L. [G, P & S, Steyerlm.]

Flowers May–October.

Occurs in waste and cultivated ground and along railroads. Known only from Greene, Jasper, and

Jackson counties, but doubtless much commoner in the state.

Native of Europe; introduced into North America, where ranging from Newfoundland to Alaska, south to Florida, Missouri, and California.

5. *Sagina* L. Pearlwort

***Sagina decumbens* (Ell.) T. & G. Pearlwort**

Map 913

Flowers March–August.

Occurs in fields, pastures, sandy or rocky open ground, sandy open wooded ridges, and waste places. Southern and central Missouri north to St. Louis, St. Charles, Franklin, Callaway, Boone, Saline, Henry, and Vernon counties.

Ranges from Florida to Texas, north to Massachusetts, Vermont, New York, Indiana, Illinois, Missouri, and Kansas.

The typical variation has petals which equal or are shorter than the sepals, or are entirely lacking in var. *Smithii* (Gray) Wats. So far as known the variety without petals has not been recorded from Missouri.

6. *Arenaria* L. Sandwort

- a. Leaves linear, thread-like or needle-like, 0.5–1.5 mm. wide; mature fruit opening by 3 valves b
- b. Leaves occurring in 2's opposite each other on the stem, without additional leaves clustered in their axils; soft annuals 4. *A. PATULA*
- b. Leaves with more than 2 clustered together and with tufts of smaller leaves in the main axils, stiff, needle-like; perennials 3. *A. STRICTA*
- a. Leaves broadened, expanded to ovate, oval, oblong, or lanceolate blades, mostly 3–15 mm. wide; mature fruit opening by 6 teeth or valves c
- c. Leaf-blades usually blunt (obtuse) at tip, the larger ones 1–3.5 cm. long; known only from woodlands of northeastern Missouri 2. *A. LATERIFLORA*
- c. Leaf-blades pointed (acute) at tip, 0.2–0.8 cm. long; common throughout the southern half of the state in fields, glades, open places, sandy or rocky soil, and scattered north of the Missouri River 1. *A. SERPYLLIFOLIA*

1. ***Arenaria serpyllifolia* L.**

Thyme-leaved Sandwort

Map 914

Flowers April–August.

Occurs in sandy or rocky soil, glades, fields, ledges

of bluffs, along railroads and roadsides, and open ground. Common throughout southern and central Missouri, but scattered northward in Ralls, Livingston, and Nodaway counties. Probably to be found in

915 *Arenaria lateriflora* (Grove Sandwort)916 *Arenaria stricta* (Rock Sandwort)917 • *Arenaria patula* var. *patula* f. *Pitcheri* (Sandwort)917 † *Arenaria patula* var. *patula* f. *media*917 □ *Arenaria patula* var. *robusta*

most of the counties north of the Missouri River.

Two variations are known in Missouri:

Fruiting calyx 3–4 mm. long, 2–3 mm. broad at base; mature fruit ovoid; leaves ovate . . .

1a. *A. SERPYLLIFOLIA* var. *SERPYLLIFOLIA*

Fruiting calyx 2–3 mm. long, 1.2–2 mm. broad at base; mature fruit narrowly ovoid to nearly cylindric; leaves lance-ovate to lanceolate . . .

1b. *A. SERPYLLIFOLIA* var. *TENUIOR*

1a. *Arenaria serpyllifolia* var. *serpyllifolia*

Map 914

Arenaria serpyllifolia L. [G, P & S, Steyererm.]

This is the common variation encountered.

Native of Europe; introduced into North America, where ranging from Quebec to British Columbia, south to Florida, Texas, and California.

1b. *Arenaria serpyllifolia* var. *tenuior*

Mert. & Koch

Map 914

Known only from southwestern Missouri in Jasper (1 mi. north of Joplin, June 8, 1951, *Palmer 49133*) and Dade (along highway near South Greenfield, June 10, 1951, *Palmer 52137*) counties.

Native of Europe; introduced and naturalized in North America from Quebec to Michigan, south to Georgia and Missouri.

2. *Arenaria lateriflora* L. Grove Sandwort

Map 915

Flowers May–August.

Occurs mostly in acid soils of upland woodland of dissected oak-hickory-clad hills, crests of ravines, rarely in low woods. Known only from northeastern Missouri, in Clark, Scotland, Schuyler, Putnam, Adair and Shelby counties.

Ranges from Labrador to Alaska, south to New Jersey, Pennsylvania, Ohio, Illinois, Missouri, South

Dakota, and New Mexico and California; also in Eurasia.

The black seeds of this species are provided with a conspicuous appendage, distinguishing it from most other species of the genus.

3. *Arenaria stricta* Michx. Rock Sandwort

Map 916

Arenaria stricta subsp. *stricta* [BB]

Arenaria stricta var. *texana* Robins. [G, P & S, Steyererm.]

Arenaria stricta subsp. *texana* (Robins.) Maguire [BB]
Flowers May–July.

Occurs on bluff escarpments, ledges, and rocky glades of limestone strata. Southern and east-central Missouri, north and east to Benton, Boone, Monroe, and Lincoln counties, in unglaciated or apparently unglaciated territory.

Ranges from New Hampshire and Quebec to Ontario and Nebraska, south to South Carolina, Kentucky, Arkansas, and Texas.

The species has been divided into subspecies or varieties, the Missouri material passing mainly as var. *texana*, distinguished from typical var. *stricta* by having leaves 5–20 mm. instead of 15–30 mm. long, by the flowering stems mainly leafy only in the lower third rather than leafy for more than half their length, and by the somewhat shorter flowering stems 5–20 cm. instead of 10–40 cm. tall.

Missouri material could be classified in either variety, with most of it passing as var. *texana*. The differences, however, do not stand out in Missouri specimens, and the variations in leaf length, stiffness, and concentration of leaves in the lower third of the stem seem to be related to the occurrence in exposed dry habitats in which the var. *texana* often occurs. In shadier bluff crevices and ledges the leaves are longer and the stem has a leafier appearance for more than half its length.

This species is a handsome gem for the limestone rock garden, but it is difficult to transplant, because the long tough root resents disturbance.

4. ***Arenaria patula* Michx.** Sandwort Map 917
Flowers April–June.

Occurs on sandstone, chert, and limestone glades and rocky sections in prairies. Throughout the Ozark region of southern and central Missouri north to St. Louis, Franklin, Gasconade, Callaway, Boone, Cooper, Johnson, and Jackson counties.

Missouri material is represented by the following variations:

- a. Leaves mostly 2–3.2 mm. broad; sepals 3-nerved; seeds 0.7–0.9 mm. wide . . . 4c. *A. PATULA* var. *ROBUSTA*
- a. Leaves mostly 0.5–1.5 mm. broad; sepals 5-nerved; seeds 0.5–0.7 mm. wide . . . b
- b. Pedicels (stalk of flower or fruit) and sepals glabrous. 4a. *A. PATULA* var. *PATULA* f. *PITCHERI*
- b. Pedicels and sepals with some glandular hairs . . . 4b. *A. PATULA* var. *PATULA* f. *MEDIA*

4a. ***Arenaria patula* var. *patula* f. *Pitcheri***
(Nutt.) Steyererm. Map 917
Arenaria patula f. *Pitcheri* (Nutt.) Steyererm. [G]
Arenaria patula var. *patula* in part [BB]

This is the more commonly encountered variation in Missouri, with the stems, leaves, pedicels, and sepals glabrous or nearly so.

Ranges from Ohio and Indiana to Minnesota, south to Virginia, Alabama, Arkansas, Kansas, Oklahoma, and Texas.

4b. ***Arenaria patula* var. *patula* f. *media***
Steyererm. Map 917
Arenaria patula f. *media* Steyererm. [G]
Scattered throughout the range in Missouri.

4c. ***Arenaria patula* var. *robusta*** (Steyererm.)
Maguire Map 917
Arenaria patula f. *robusta* Steyererm. [G]

Known only from open sandy ground in open woods in Butler County, southeastern Missouri (Gillis Bluff, sect. 8 and 17, 5 mi. southwest of Quilín, May 27, 1939, *Steyermark 26652*).

Ranges from Kentucky, Tennessee, and Missouri, south to Arkansas, Kansas, and Texas.

Some intergradation occurs between var. *robusta* and var. *patula* f. *media*, and frequent intergradation occurs between the forms of *A. patula* var. *patula*. Apparently, typical *A. patula* var. *patula* f. *patula*, with the stems and leaves with glandular hairs, does not occur in Missouri, or at least no specimens have thus far been recorded.

Except for var. *robusta*, which is isolated in sandy open woods on Crowley Ridge in Butler County, all the other variations of *A. patula* are on rocky glades of usually limestone strata in the Ozark section, although plants occur also on sandstone and chert glades and barrens. While in flower, the numerous dainty white blossoms carpet the glades so thickly that they suggest natural rock gardens. The species has a very brief flowering season, beginning in April and ending in June at which time the seed is ripened and the plant dies. Seeds germinate the following autumn and the plant lives over the winter as a winter annual, recognized by threadlike little leaves on the ground.

7. ***Stellaria* L.** Chickweed, Starwort

- a. Leaves ovate to elliptic or elliptic-oblong, noticeably broadest around the middle or near the base, $1\frac{1}{2}$ – $4\frac{1}{2}$ times as long as broad, mainly 8–45 mm. wide; stems with short hairs, often appearing in 2 vertical lines b
- b. Lower and middle leaves of plant with a stalk (petiole); leaf-blades ovate, 5–40 mm. long; sepals longer than the petals; common species 1. *S. MEDIA*
- b. Most of leaves sessile (without a stalk); leaf-blades elliptical to elliptic-oblong, 20–100 mm. long; sepals shorter than the petals; rare species, known only from Franklin County 2. *S. PUBERA*
- a. Leaves narrow, linear to oblanceolate, mainly of approximately the same width throughout, 6–10 or more times as long as broad, 1.5–7 mm. wide; stems glabrous (without hairs) c
- c. Flowering branch arising from the very top of the leafy stem; sepals 4–5.5 mm. long; leaves often broadest at the base; rare introduced plant known from open grassy lawns in Boone County. 3. *S. GRAMINEA*
- c. Flowering branch arising at the side of the leafy stem below the very tip; sepals 2.5–4 mm. long; leaves often broadest at or above the middle; native species of low wet woods, wooded swamps, and open wet meadows in eastern Missouri 4. *S. LONGIFOLIA*

Plate no. 157. 1. *Arenaria patula*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden. 2. *Stellaria media*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden. 3. *Stellaria pubera* var. *pubera*, $\times \frac{2}{5}$. 4. *Stellaria graminea*, $\times \frac{2}{5}$. 5. *Stellaria longifolia*, $\times \frac{2}{5}$.

PLATE NO. 157

918 *Stellaria media* var. *media* (Common Chickweed)919 *Stellaria pubera* var. *pubera* (Great Chickweed)920 *Stellaria graminea* (Common Stitchwort)

1. *Stellaria media* (L.) Cyrillo var. *media*

Common Chickweed

Map 918

Flowering January through December.

Occurs as a weed in lawns, gardens, and about dwellings, waste ground, roadsides, along railroads, sometimes in low woodland and valleys. Common in southern and central Missouri, and doubtless occurring throughout northern Missouri, but recorded there only from Marion, Caldwell, and Andrew counties.

Native of Europe; introduced and naturalized throughout North America; also naturalized in Guatemala in Central America and South America.

A var. *glaberrima* G. Beck, differing from var. *media* in being completely glabrous throughout, has not yet been found in Missouri.

In Europe the plant is sometimes cooked as a vegetable as a spinach substitute, but only the younger growing tips are recommended for use. The small seeds are sometimes found in seed used for cage birds. Cases of poisoning are reported where young lambs have eaten quantities of the plant. However, hogs and rabbits eat the plants, and domestic fowl and wild birds are fond of the seed.

2. *Stellaria pubera* Michx. var. *pubera*

Great Chickweed

Map 919

Stellaria pubera var. *silvatica* [of P & S, Steyermark.], not (Béguinot) Weath.

Flowers late March–May.

Known only from Franklin County, east-central Missouri (Gray Summit, April 20, 1927, *Kellogg* in herb. Mo. Bot. Gard.).

Ranges from New Jersey to Indiana, Illinois, and Missouri, south to Florida.

The leaves of the Missouri specimen are sessile and the plant should be referred, therefore, to var. *pubera* instead of to var. *silvatica*, as treated in Palmer and Steyermark's *Annotated Catalogue*.

The Missouri record is probably based upon a planted specimen originally grown at the Missouri

Botanical Garden's Arboretum at Gray Summit in Franklin County. Native Missouri plants as well as some not native were introduced there, and Kellogg's specimen gives no detailed data concerning its origin. Unfortunately, no other records are available at the Arboretum that would indicate the introduction of this species there. The plant thrives in shaded wildflower gardens and spreads over the years, often forming dense carpets over the soil. It prefers rich loose humus. The white starlike flowers, produced in early spring, are attractive against the dark green leafy background.

3. *Stellaria graminea* L. Common Stitchwort

Map 920

Flowers May–October.

Known only from grassy open ground in Boone County, central Missouri, where introduced (University campus, Columbia, May 31, 1929, *Rickett*, in herb. Univ. Mo.).

Native of Europe; introduced and naturalized in North America from Newfoundland and Quebec to Ontario and Minnesota, south to North Carolina, West Virginia, Ohio, Indiana, Illinois, and Missouri; also Washington.

Broad-leaved plants are sometimes treated as var. *latifolia* Peterm., but the Missouri specimen appears referable to typical *S. graminea*.

4. *Stellaria longifolia* Muhl.

Long-leaved Stitchwort

Map 921

Flowers May–July.

Occurs in low wet woods, wooded swamps, and wet meadows. Known only from eastern Missouri, where found from Butler and Scott counties north to St. Louis County and locally in northeastern Missouri in Clark County.

Ranges from Labrador and Newfoundland to Alaska, south to South Carolina, Kentucky, Missouri, Louisiana, Nebraska, New Mexico, and Arizona. Also in Europe and Asia.

8. *Cerastium* L. Mouse-ear Chickweed

The European and South American species have been recently studied by Dr. W. Möschl of Austria.

- a. Petals normally absent 5b. *C. VISCOSUM* f. *APETALUM*

a. Petals (except in mature fruiting plants) normally present b

b. Petals showy, 2–3 times as long as sepals, 10–15 mm. long; plants perennial with overwintering leafy offshoots or branches attached at base 2. *C. ARVENSE* var. *VILLOSUM*

b. Petals shorter than or equaling or somewhat longer than the sepals, only 4–6 mm. long; mostly annuals with a delicate root-system and no overwintering leafy offshoots at the base, or, if perennials as in *C. vulgatum*, the petals only 4–6 mm. long c

c. Perennial plants with overwintering leafy offshoots or branches attached at base; leaves thick; stems often purplish at least at base; upper bracts of inflorescence with broad scarious margins (thin, whitish, or transparent); stamens 10 1. *C. VULGATUM*

c. Annual plants with a delicate root system and without the above combination of characters; if stems purplish, then the bracts are green throughout and leaf-like in texture, and not scarious-margined, or the stamens are 4–5, or the plants are annuals; stamens 4, 5, or 10 d

d. Stamens 4 or 5 e

e. Bracts of the inflorescence green throughout and similar to the leaves in texture; stamens mainly 4, sometimes 5 6. *C. TETRANDUM*

e. Bracts of the inflorescence with thin, whitish, transparent, or colorless summit or margin, not green throughout; stamens mainly 5. f

f. Upper half of bracts scarious (thinner, transparent, colorless, or whitish); sepals with broad scarious margins and tips, the scarious or white part occupying about $\frac{1}{2}$ of the sepal width; petals shallowly notched, none of the veins branched 8. *C. SEMIDECANDRUM*

f. Only the narrow margin and summit of the bracts and sepals scarious, the scarious or white part of the sepal occupying only about $\frac{1}{2}$ its width; petals deeply 2-cleft about $\frac{1}{4}$ way from the tip, at least the lateral veins with a simple fork above 9. *C. PUMILUM*

d. Stamens 10 g

g. Bracts of inflorescence ending in long tufts of hairs; entire plant covered with long hairs, the hairs in life giving a grayish-white hairy appearance to the plant; filaments of the stamens and claws of the petals long-ciliate (hairy on margins) 7. *C. BRACHYPETALUM*

g. Without the above combination of characters; bracts not as above nor hairs so long as to give a gray-hairiness in life; filaments of stamens and claws of petals glabrous. h

h. Stalks (pedicels) of fruits 2–5 mm. long, shorter than or as long as the calyx; inflorescence compact, the flowers bunched close together, even at maturity the terminal clusters close together; leaves firm and thickish; leaves at the middle of the stem ovate or oblong-obovate, usually blunt to rounded at tip, $1\frac{1}{2}$ –3 times as long as broad; sepals all sharply pointed at tip; sepals mainly covered with long hairs both gland-tipped and non-glandular 5. *C. VISCOSUM*

h. Stalks (pedicels) of fruits 4–55 mm. long, equaling to 12 times as long as the calyx; inflorescence open and loosely flowered; leaves thin and membranous; leaves at the middle of the stem lanceolate, oblong-lanceolate, or of an elongated type, acute or acutish (rather short-pointed) at tip, mainly 4–9 times as long as broad; at least the outer sepals rather blunt at tip; sepals mainly covered with short gland-tipped hairs i

i. At least the lower stalks of the fruit much longer than the capsules, 10–55 mm. long; pedicels (stalks) hooked or curved at tip; leaves mainly acute or short-pointed at tip, the well-developed ones 4–5 times as long as the calyx 3. *C. NUTANS*

i. Stalks of the fruit shorter than or but slightly longer than the capsules, mainly 4–10 mm. long; pedicels (stalks) not hooked nor curved at tip; leaves mainly obtuse or blunt at tip, the well-developed ones not more than twice as long as the calyx 4. *C. BRACHYPODUM*

1. *Cerastium vulgatum* L. Common Mouse-ear Chickweed
Map 922
Flowers April–November.
Occurs in fallow and cultivated fields, pastures, moist meadows, farmlots, on lawns about dwellings,

along roadsides and railroads, and open and grazed woodland. Throughout Missouri, and doubtless in every county, but not recorded from a number of northern Missouri counties and elsewhere.
Native of Eurasia; introduced and naturalized

921 *Stellaria longifolia* (Long-leaved Stitchwort)922 • *Cerastium vulgatum* var. *vulgatum* f. *vulgatum*
(Common Mouse-ear Chickweed)922 □ *Cerastium vulgatum* var. *vulgatum* f. *glandulosum*923 *Cerastium arvense* var. *villosum* f. *oblongifolium*

throughout temperate North America.

Missouri material is represented by the following variations:

Stems covered with hairs which are not gland-tipped . 1a. *C. VULGATUM* var. *VULGATUM* f. *VULGATUM*
Stems covered with gland-tipped hairs

1b. *C. VULGATUM* var. *VULGATUM* f. *EGLANULOSUM*

Cerastium vulgatum L. [G]

Cerastium vulgatum var. *hirsutum* Fries. [P & S, Steyer., BB]

This is the more commonly encountered variation in Missouri.

1b. ***Cerastium vulgatum* var. *vulgatum* f. *glandulosum***. (Boenn.) Druce Map 922

Cerastium vulgatum f. *glandulosum* (Boenn.) Druce [G, BB]

Scattered throughout the range of the var. *vulgatum*, but less frequent.

2. ***Cerastium arvense* L. var. *villosum* (Muhl.) Hollick & Britt. f. *oblongifolium* (Torr.) Pennell** Map 923

Cerastium arvense var. *oblongifolium* (Torr.) Hollick & Britt. [P & S, Steyer., BB]
Flowers April–June.

Occurs along rocky stream banks, on moist open or wooded ledges and outcrops of sandstone, granite, and limestone rock, and on limestone talus and rocky slopes of bluffs. Eastern Missouri from Butler County north to St. Louis and Warren counties.

Ranges from Ontario to Idaho, south to Virginia, Tennessee, and Missouri.

This form of *C. arvense* is recognized by the glabrous or nearly glabrous upper surface of the green, mostly lanceolate leaves, which are 3–10 mm. broad, and up

to 6.5 cm. long. This is a very ornamental plant with large, attractive white flowers. It does well in wild-flower rock gardens, on either siliceous or limestone rocks.

3. ***Cerastium nutans* Raf. Nodding Chickweed** Map 924

Cerastium nutans Raf. var. *nutans* [BB]

Flowers March–June.

Occurs in low ground of valleys in fallow and cultivated fields, moist meadows and pastures, open or rocky woodland, and ledges along streams. Throughout Missouri, doubtless in every county.

Ranges from Quebec to British Columbia, south to Florida, Alabama, Arkansas, Texas, New Mexico, and Arizona.

Petals are occasionally wanting in cleistogamous flowers of this species.

4. ***Cerastium brachypodum* (Engelm.) Robins.** Map 925

Cerastium nutans var. *brachypodum* Engelm. [BB]

Flowers March–June.

Occurs in open woods, rocky slopes, moist meadows, cultivated and fallow fields, waste ground, and along roadsides and waste ground. Occurs commonly throughout the southern half of the state, north to St. Charles, Warren, Boone, Carroll, and Jackson counties.

Ranges from Guatemala to Mexico, and Georgia to Arizona, north to Virginia, Tennessee, Illinois, North Dakota, Alberta, and Washington.

In general this species seems sufficiently distinct from the preceding one, *C. nutans*. In the main, the stems are shorter and the leaves are smaller, usually not exceeding 3 cm. long. Some specimens collected from the northern part of the state, previously determined as *C. brachypodum*, are now referred to *C. nutans*. Throughout the southern half of the state the plants

924 *Cerastium nutans* (Nodding Chickweed)

925 *Cerastium brachypodium*

926 • *Cerastium viscosum* f. *viscosum* (Clammy Chickweed)
926 † *Cerastium viscosum* f. *apetalum*

appear more uniformly constant and clearly recognizable.

5. ***Cerastium viscosum* L.** Clammy Chickweed. Map 926

Cerastium glomeratum Thuillier [Shinners]
Flowers March–July.
Occurs in fallow and cultivated fields, pastures, along roadsides and waste ground, wet rocky and open woodland, and open rocky places.

Native of Europe; introduced and naturalized in North America from Florida to Texas and California, north to Newfoundland, Ontario, and British Columbia.

Missouri material is represented by the following variations:

- Petals present, somewhat shorter than the sepals
or about equaling them 5a. *C. VISCOSUM*
f. *VISCOSUM*
Petals either completely absent or so minute as
to be very inconspicuous 5b. *C. VISCOSUM*
f. *APETALUM*

5a. ***Cerastium viscosum* f. *viscosum*** Map 926

This is the more commonly encountered form in the state. Known only from southern and central Missouri north to St. Charles, Boone, Howard, and Jackson counties; to be expected in the northern half of the state, but not recorded as yet from that section.

5b. ***Cerastium viscosum* f. *apetalum*** (Dumort.) Mert. & Koch Map 926

Known only from Pettis County, west-central Missouri (open grassy ground on top of ridge on cherty limestone upper slopes above northwest-facing wooded bluffs along Flat Creek, T45N, R21W, sect. 24, 2½ mi. south of Sedalia, May 20, 1949, *Steyermark* 67973). Undoubtedly to be found in most parts of the range of typical f. *viscosum*.

Most of the small annual species of *Cerastium*, such

as *C. viscosum*, and others treated in the present work, may be used as cooked vegetables if gathered very early in spring while still in the leafy and non-flowering stage of growth.

Cerastium viscosum usually grows as a small plant with erect or ascending stems with closely crowded flowers at the tip. The stems and sepals are usually covered with gland-tipped hairs, while the thickish leaves are mainly hirsute and nonglandular. In some specimens the stems have mostly spreading, nonglandular hairs.

6. ***Cerastium tetrandrum* Curtis** Map 927
Flowers March–May.

Known only from Crawford County, eastern Missouri (along highway 8, south of Scotia, between highway to Scotia and Huzzah Creek, April 28, 1957, *Steyermark* 83932, 83934).

Native of Europe; introduced into the United States, where now recorded from Virginia and Missouri.

Since this species is just becoming established along highways and is not fully described in the standard manuals, the following short description is given to aid further in the identification of the plant: Stems 3–20 cm. tall, slender, with short gland-tipped hairs. Middle and upper leaves ovate, obtuse to acute, 7–17 mm. long, 3–6 mm. broad, the lower ones elliptic to elliptic-obovate, narrowed at base and more pointed, densely pubescent with rather stiff mostly nonglandular hairs. Pedicels 4–13 mm. long, covered with short gland-tipped hairs equaling or longer than the calyx. Sepals are scarious-margined, 4–4.5 mm. long, and covered with mostly gland-tipped hairs. The claws of the petals are glabrous, and the 4 or 5 stamens are also glabrous. Capsule 7–8 mm. long, slightly curved, not quite twice the length of the calyx, at maturity reaching 2–5 times the length of the pedicels.

The plants resemble *C. viscosum* in general habit,

927 *Cerastium tetrandrum*928 *Cerastium brachypetalum*929 *Cerastium pumilum*

but the cymose inflorescence is more open and loose with a dichotomous or forked branching, the leaves average smaller, the stems more slender, and the pedicels longer, especially in fruit. This species eventually will probably be found in all the counties of southern and central Missouri.

7. ***Cerastium brachypetalum* Pers.** Map 928
Flowers April–May.

Occurs along highways and pastured hills, where now known in four counties in the southern third of the state. First collected in 1954 by Harry Ahles in Ste. Genevieve County (pastured hillside, 1 mi. north of Zell, April 30, 1954, *Ahles 7930*, in herb. Univ. of Ill.), and more recently collected in Miller (fallow field along highway 52, 3 mi. northwest of Tuscumbia, May 6, 1957, *Steyermark 83988*), Phelps (along highway 66, just southwest of junction of highway 63 and 66, northwest of Rolla, April 21, 1957, *Steyermark 83643*), and Wayne (along highway 34, 2 mi. west of Piedmont, May 4, 1958, *Steyermark, Voigt, and Mohlenbrock 86097*) counties.

Native of Europe; introduced into the United States, where at present known from Virginia and Missouri.

This is another one of the annual species of Mouse-ear Chickweed which has recently become introduced in the state along highways. It is predicted that the species will eventually be found at least throughout all the southern and central Missouri counties.

In the field the plant has a characteristic gray-hairy appearance. It usually occurs in dense masses so that at a distance the spreading gray-white hairs, which densely cover the stems, leaves, pedicels, bracts, and sepals, stand out conspicuously. Superficially, the plants resemble *C. vulgatum*, but differ in their slender

roots with annual habit, without persistent leafy offshoots, ciliate filaments of stamens and claws of the petals, and the conspicuous long tufts of hairs on the nonscarious margined bracts of the inflorescence. The stems are usually 10–25 cm. tall, the leaves are elliptical-oblong to ovate-oblong, obtuse or slightly acute, 7–18 mm. long, and 4–7 mm. broad. The pedicels are 4–17 mm. long, and at maturity are 2–5 times the length of the calyx. The filaments of the 10 stamens and claws of the petals are ciliate.

All parts of the plant are usually covered with long nonglandular hairs. Most of the Missouri material seen appears to belong to this category and is known as ***Cerastium brachypetalum* f. *brachypetalum***

Cerastium brachypetalum var. *strigosum* (Fries.) Aschers. & Graebn. Syn. 5: 680. 1918; *Cerastium brachypetalum* subsp. *strigosum* (Fries.) Lousing; *Cerastium brachypetalum* var. *eglandulosum* Fenzl in Ledeb. Fl. Ross. 1: 404. 1842.

The form with glandular hairs on the sepals and stems is known from Ste. Genevieve County (*Ahles 7930*) and is known as ***Cerastium brachypetalum* f. *glandulosum*** Koch, Syn. Fl. Germ. & Helv. 1: 121. 1835.

Cerastium brachypetalum subsp. *tauricum* (Sprengel) Murbeck

8. ***Cerastium semidecandrum* L.**

Excluded species. Easily confused with *C. pumilum*, but doubtless to be found eventually in the state.

A specimen from Bates County (waste places, Amoret, May 15, 1936, *Bush 15493* in Mo. Bot. Gard. Herb.) labeled *C. semidecandrum* is a misidentified *C. vulgatum*. It has a perennial habit, mostly 10 stamens, and other characteristics of *C. vulgatum*. See the discussion under the next species, *C. pumilum*.

Plate no. 158. 1. *Cerastium vulgatum*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden. 2. *Cerastium arvense* var. *villosum* f. *oblongifolium*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden. 3. *Cerastium nutans*, $\times \frac{2}{5}$. 4. *Cerastium viscosum*, $\times \frac{2}{5}$. 5. *Holosteum umbellatum*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden.

PLATE NO. 158

9. **Cerastium pumilum** Curtis Map 929
Flowers April–May.

Occurs along highways in southern Missouri in Cape Girardeau (along highway 34, just west of junction with road U near Bollinger Co. line, May 4, 1958, *Steyermark, Voigt, and Mohlenbrock 86106*) and Dallas (along highway 43, 1 mi. north of Buffalo, May 2, 1958, *Steyermark, Voigt, and Mohlenbrock 86064*) counties. Doubtless to be eventually expected in most of the counties of southern and central Missouri.

Native of Europe; introduced into the United States, where known at present from New Jersey and Missouri.

Like *C. tetrandrum* and *C. brachypetalum*, this species has just been recently introduced in the state, but will doubtless eventually be found as a weed in most of the counties of the southern and central part of the state. The differences by which it is separated from *C. semidecandrum* L., another European species, seem slight, and perhaps eventually *C. pumilum* may be found synonymous with *C. semidecandrum* in Missouri. The main differences between the two are based largely on the simple or forked veins of the petals and relative proportion of scarious to non-scarious surface of the bracts and sepals as stated in the keys. The two Missouri collections cited are

intermediate between *C. semidecandrum* and *C. pumilum*, combining conspicuously margined bracts and sepals, characteristic of *C. semidecandrum*, with simply forked veins, more characteristic of *C. pumilum*. In the Missouri collections cited, the midvein is simple and unbranched, while the lateral veins are simply forked in the upper part. It is upon the basis of the forked lateral veins that the cited collections are placed with *C. pumilum*. There would also appear to be some difference of opinion and interpretation as to the relative conspicuousness of the scarious portion of the bracts and sepals in the Missouri material. Hegi's illustration of the two species (*Ill. Fl.* Band III, teil 1: 365–66, fig. 601, e–p, q–t) shows the broad scarious margin of the sepals in *C. semidecandrum* occupying one-half or more of the sepal, whereas in *C. pumilum* the narrow scarious margin occupies only about one-fifth of the sepal. In the Missouri material the outer sepals have a broad scarious margin, like that of *C. semidecandrum*, whereas the inner sepals have a narrow scarious margin of *C. pumilum*.

The sepals in these collections are 3.5–5 mm. long. The stems, pedicels, and sepals are covered with glandular hairs. The leaves vary from oblong or elliptic to broadly ovate.

9. **Holosteum** L. Jagged Chickweed

Holosteum umbellatum L. Jagged Chickweed Map 930

Flowers March–May.

Occurs along roadsides and railroads. Recently introduced in the state (known since 1950) and now spreading rapidly. Established in southern and central Missouri north to St. Louis and Boone counties. First recorded from Washington County in 1950 (one mile south of Caledonia, April 22, 1950, *Ahles*).

Native of Europe; introduced and naturalized in

the United States from Massachusetts and Pennsylvania, south to Georgia, Kentucky, Ohio, and Missouri.

After a brief flowering the plants quickly become dried and tawny brown and disappear. Like other early spring annuals, they often occur in dense masses at the time of flowering. Eventually this species undoubtedly should spread over the greater portion of the state, as detailed highway collecting will probably reveal.

10. **Agrostemma** L. Corn Cockle

Agrostemma Githago L. Corn Cockle Map 931
Flowers late May–September.

Occurs in fallow and cultivated (usually grain) fields, waste ground, and along roadsides and railroads. Known in most parts of southern and central Missouri, but recorded northward from only Clark, Livingston, and Caldwell counties. Undoubtedly of expected occurrence in all the counties.

Native of Europe; introduced and naturalized

throughout most of North America.

The seeds of this hairy annual are poisonous, and poultry and stock fed with wheat screenings containing Corn Cockle seeds are sometimes known to have died afterwards. When ground with wheat flour, it may cause poisoning, if a large enough quantity becomes included, as well as give the flour a poor taste. The seeds have been used in medicine for gastritis and paralytic cases, according to reports in herbals.

11. *Lychnis* L. Campion

Petals usually rose-colored, rose-purple, or pink, rarely white, opening in the morning; teeth of the calyx short-pointed, triangular-lanceolate; mature capsule nearly as long as broad, the teeth recurved when the capsule opens 1. *L. DIOICA*

Petals usually white, rarely pinkish, opening in the evening and early morning; teeth of the calyx slenderly tapering, lanceolate-linear; mature capsule conical-ovoid, tapering and narrowed at tip, the teeth either erect or slightly spreading when the capsule opens 2. *L. ALBA*

- 1. ***Lychnis dioica* L.** Red Campion Map 932
Flowers late May–September.
Known only from Jackson County, west-central Missouri.

Native of Eurasia; introduced and naturalized from Newfoundland to Ontario, south to Delaware, Pennsylvania, Ohio, Illinois, and Missouri.

- 2. ***Lychnis alba* Mill.** White Campion Map 933
Flowers late May–September.

Occurs in fallow and cultivated fields, waste ground, and along roadsides and railroads. Scattered throughout Missouri, and to be expected in every county.

Native of Europe; introduced and naturalized in North America from Quebec to British Columbia, south to North Carolina, Ohio, Indiana, Illinois, Missouri, Kansas, Colorado, Utah, and California.

The flowers are quite fragrant. This species and *Silene noctiflora* are both night-flowering plants with

fragrant white flowers. While they are frequently confused, the essential differences between them are as follows:

Styles 5; flowers mostly unisexual, either entirely with stamens or entirely with pistils, and these on different plants, rarely some perfect flowers scattered among the unisexual ones; plants biennial or short-lived perennial with coarsely hairy stems with rather conspicuous hairs; calyx with 20 nerves, of which 10 are strong and 10 faint; lobes of calyx triangular-lanceolate, acute, 3–5 mm. long; teeth of capsule 10, each of the main 5 teeth split in 2 . *LYCHNIS ALBA*
Styles 3; flowers perfect, with the stamens and pistils in the same flowers, smaller than in *Lychnis alba*; plants annual with hairs of stem short and not conspicuous; calyx with 10 nerves; lobes of calyx linear-lanceolate, slenderly pointed (subulate), 4–8 mm. long; teeth of capsule 6 .

SILENE NOCTIFLORA

12. *Silene* L. Catchfly, Campion

- a. Most of leaves, or at least those at the middle of the stem, in whorls of 4's; petals fringed 8. *S. STELLATA*
- a. All the leaves in 2's opposite each other; petals not fringed, but notched or cut, or sometimes minute, inconspicuous, or absent b
- b. All parts of stem glabrous (without hairs); calyx glabrous or with only minute hairiness at base c
- c. Leaves on the stem narrow, linear or linear-elliptic to oblanceolate, 1–12 mm. broad; some part of the stem (at least the upper part) with a dark sticky area 1. *S. ANTIRRHINA*
- c. Leaves on the stem broader, from lanceolate to lanceolate-oblong or ovate, 8–50 mm. broad; stem completely smooth, without any sticky area d
- d. Stems and leaves green; flowers few on a plant, solitary on slender, spreading pedicels (stalks) arising from the upper leaf axils; expanded blades of petals about 8 mm. long, each with a

- small scale crowning the base; calyx with veins scarcely showing between the nerves . 7. *S. NIVEA*
- d. Stems and leaves gray-silvery green, glaucous (with a coating which can be rubbed off); flowers rather numerous, more closely grouped in a bracted inflorescence; expanded blades of petals 2–6 mm. long, without any scale crowning the base; calyx with the veins prominent between the nerves 6
- e. Calyx becoming 10–13 mm. in fruit, firm, not inflated or very slightly inflated in fruit but the summit of the calyx in contact with and lying against the protruding capsule; nerves of calyx not or scarcely connected by the veins; calyx not constricted at the summit 5. *S. CSEREI*
- e. Calyx becoming 20 mm. in fruit, papery, much inflated in fruit, not at all in contact with the included capsule; nerves of calyx connected with one another their entire length by veins; calyx constricted at the summit 6. *S. CUCUBALUS*
- b. At least the lower part of the stem hairy with short or long hairs; calyx hairy (or if glabrous in *S. antirrhina* the stems have a dark sticky area) f
- f. Some part of the stem with a dark sticky area (except in *S. antirrhina* f. *Deaneana*); at least the upper portion of stem glabrous (without hairs) 1. *S. ANTIRRHINA*
- f. Stem completely lacking dark sticky areas; stems completely hairy g
- g. Most of the petal or all of it white; expanded part of petals 5–12 mm. long h
- h. Calyx with about 30 prominent green ribs, conical and tapering from a broad base . 2. *S. CONOIDEA*
- h. Calyx with 5–10 prominent ribs, not conic nor tapering from a broad base i
- i. Calyx mainly 15–23 mm. long; lobes of calyx mainly 5–9 mm. long; leaves ovate-lanceolate, the lower spatulate or elliptic-ob lanceolate, 10–50 mm. wide; flowers opening at night 9. *S. NOCTIFLORA*
- i. Calyx mainly 6–16 mm. long; lobes of calyx 3–4 mm. long; leaves lanceolate, linear-oblong to spatulate, mainly 3–18 mm. wide (rarely to 35 mm.); flowers opening during the day j
- j. Inflorescence forking, the flowers nodding; leaves with an acutely pointed, tapering tip; petals deeply cut more than half way; ribs on calyx covered by a comb-like arrangement of hairs; fruiting calyx 10–16 mm. long 4. *S. DICHOTOMA*
- j. Inflorescence simple and 1-sided, raceme-like, the flowers ascending; leaves with a rounded or blunt broadened tip; petals at most with only a slight notch at the tip; calyx covered with hairs, lacking any regular pattern of arrangement; fruiting calyx 7–10 mm. long 3. *S. GALLICA*
- g. All of the petal red, rose-red, or deep pink; expanded part of petals 8–22 mm. long k
- k. Leaves of the stem in 10–30 pairs, thickish, lanceolate to ovate, most of them rounded at base or clasping; flowers mainly June–October; stems mainly 80–120 cm. tall; plants of prairies and rocky open places 12. *S. REGIA*
- k. Leaves of the stem in 2–6 pairs, thin, oblanceolate to oblong-spatulate, the middle and lower ones tapering or narrowed at the base and not clasping; flowers mainly April–May; stems mainly 8–60 cm. tall; plants mainly of open woodland and wooded rocky ledges, sometimes in exposed cuts along roadsides l
- l. Flowers red or scarlet, the petals usually split at the tip and with linear-oblong blades 20–25 mm. long; plants usually 20–60 cm. tall 11. *S. VIRGINICA*
- l. Flowers deep pink or rose-pink, the summit of the petals either smooth-edged or with slightly wavy edges, the blade of the petals wedge-shaped (cuneate-obovate) and 8–15 mm. long; plants usually 8–20 cm. tall 10. *S. CAROLINIANA* var. *WHERRYI*
- l. Flowers deep pink or rose, the petals split at the tip and with linear-oblong blades; plants 8–20 cm. tall 11a. *S. VIRGINICA* × *S. CAROLINIANA* var. *WHERRYI*
1. ***Silene antirrhina* L.** Sleepy Catchfly Map 934
Flowers April–September.
Occurs along roadsides and railroads, pastures,
rocky ledges of bluffs, rocky open glades, fallow and
cultivated fields, waste places, and alluvial or open
woodland. Throughout Missouri.
Ranges from Quebec to British Columbia, south
to Florida, California, and Mexico; also in South

Plate no. 159. 1. *Agrostemma Githago*, × $\frac{2}{7}$; Details from Small, The New York Botanical Garden. 2. *Lychnis alba*, × $\frac{2}{7}$; Details from Small, The New York Botanical Garden. 3. *Silene antirrhina*, × $\frac{2}{7}$. 4. *Silene gallica*, × $\frac{2}{7}$. 5. *Silene Cserei*, × $\frac{2}{7}$. 6. *Silene conoidea*, × $\frac{2}{7}$; After Gleason, The New York Botanical Garden. 7. *Silene Cucubalus*, × $\frac{2}{7}$. 8. *Silene dichotoma*, × $\frac{2}{7}$.

PLATE NO. 159

933 *Lychnis alba* (White Campton)

934 ● *Silene antirrhina* f. *antirrhina* (Sleepy Catchfly)
 934 † *Silene antirrhina* f. *bicolor*
 934 □ *Silene antirrhina* f. *apetala*
 934 x *Silene antirrhina* f. *Deaneana*

934A *Silene conoidea*

America, and introduced in Europe.

Missouri material is represented by the following variations:

- a. No sticky (glutinous) area present on any part of stem or branches of inflorescence 1d. *S. ANTIRRHINA* f. *DEANEANA*
- a. A sticky (glutinous) area present on some part of stem or branches of inflorescence b
- b. Petals normally absent 1c. *S. ANTIRRHINA* f. *APETALA*
- b. Petals normally present, although small or inconspicuous c
- c. Petals pink, rose, or purplish 1a. *S. ANTIRRHINA* f. *ANTIRRHINA*
- c. Petals white above, pink or rose or purplish below 1b. *S. ANTIRRHINA* f. *BICOLOR*

1a. ***Silene antirrhina* f. *antirrhina*** Map 934
Silene antirrhina L. [G, BB, P & S, Steyermark.]

This is the commonly encountered form in the state. Doubtless to be found in every county of the state.

1b. ***Silene antirrhina* f. *bicolor*** Farw. Map 934

Known only from Wright County (fallow field by cemetery, by Webster County line, along headwaters of Bryant Creek, T28N, R16W, sect. 22 and 27, 1-1½ mi. [by air] southwest of Cedar Gap, April 26, 1955, *Steyermark* 78373), southern Missouri, but doubtless to be found throughout the state.

1c. ***Silene antirrhina* f. *apetala*** Farw. Map 934
Silene antirrhina var. *divaricata* Robins. [BB, P & S, Steyermark.]

Scattered throughout the range of f. *antirrhina* in the state, but less common.

1d. ***Silene antirrhina* f. *Deaneana*** Fern. Map 934

Known only from Cooper Co., central Missouri

(along west side of road by field along Moniteau Creek, T46N, R16W, W half sect. 19 and E half sect. 24, 4½-5 mi. [by air] southeast of Pisgah, 6 mi. southwest of Prairie Home, April 27, 1955, *Steyermark* 78400). Doubtless to be found throughout the state when better collected.

The sticky areas of *S. antirrhina* sometimes trap ants at the time of flowering. Those plants of the species found in Missouri in woodland areas may be native to the state, others encountered as weeds in fields, or along roadsides and railroads may have originated from an introduced strain not native to the state. This is a problem which future studies may work out more clearly.

2. ***Silene conoidea* L.**

Map 934a

Flowers May-July.

Occurs along railroads. Known only from St. Louis County (St. Louis, Baden freight yard of Mo.-Kan.-Tex. R.R. between the two most western sidings, June 14, 1959, *Muehlenbach* 1538).

Native of Europe; introduced in the United States along the Pacific Coast, and locally in Delaware and Missouri.

This species closely resembles *S. conica* L., from which it differs in the larger fruiting calyx (20-30 mm. instead of 17 mm. or less), inflated in fruit, blades of the petals 8-12 mm. long instead of 3-6 mm., and seeds 1.2-1.5 mm. instead of 0.6-0.9 mm. wide.

3. ***Silene gallica* L. f. *gallica***

Map 935

Silene gallica L. [G, BB, P & S, Steyermark.]

Flowers April-September.

Occurs in fallow fields and waste ground. Known only from Cape Girardeau (*Steyermark* 4813) and Jackson (*Bush* 2056, 3023) counties.

Native of Europe; introduced and naturalized in North America from Nova Scotia to Michigan, south

935 *Silene gallica* f. *gallica*936 *Silene dichotoma* (Forking Catchfly)937 *Silene Cserei*

to New Jersey, Illinois, Missouri, and Texas, and in the Pacific states; also naturalized in Central and South America.

The ordinary f. *gallica* has the petals white; in f. *quinquevulnera* (L.) Mert. & Koch, not known in Missouri, the petals are purple or dark brownish-red.

4. ***Silene dichotoma* Ehrh. Forking Catchfly**
Map 936

Flowers June–September.

Occurs along railroads. Known only from St. Louis County (Burlington Railroad, between East Grand Ave. and Ferry St. along the siding, St. Louis, July 9, 1955, *Muehlenbach* 672).

Native of Europe; introduced and naturalized in North America from Quebec to Montana, south to Virginia, Missouri, Texas, and California.

5. ***Silene Cserei* Baumg.**
Flowers May–September.

Occurs in waste ground and along railroads. Known from St. Louis, Livingston, and Grundy counties.

Native of Europe; introduced and naturalized in the United States from New York to Montana, south to New Jersey, Pennsylvania, Ohio, Indiana, Illinois, and Missouri.

6. ***Silene Cucubalus* Wibel var. *Cucubalus***
Bladder Campion
Silene latifolia (Mill.) Britten & Rendle [P & S, Steyer.]

Map 938

Flowers May–August.

Occurs in fields, waste ground, and along railroads. Known from St. Louis, Taney, Jackson, and Platte counties.

Native of Europe; introduced and naturalized in North America from Newfoundland to British Columbia, south to Virginia, Tennessee, Missouri, Kansas, Colorado, and Oregon.

The young leafy shoots just emerging above the ground are sometimes gathered and used as a cooked vegetable or made into a thick soup.

7. ***Silene nivea* (Nutt.) Otth Snowy Campion**
Map 939

Flowers early June–August.

Occurs in alluvial soils of wooded valleys and flood plain forest, wooded stream banks, and occasionally found along railroads and waste ground. Rather rare and scattered in northern and central Missouri south to Franklin, Callaway, Boone, and Caldwell counties.

Ranges from Pennsylvania to Minnesota and South Dakota, south to Maryland, Virginia, Tennessee, Missouri, and Nebraska.

The stems are rather slender and weak, sometimes half-sprawling among other herbaceous plants. The leaves are thin, resembling those of *Phlox paniculata* in shape. The solitary flowers are on slender spreading pedicels, appearing from the upper axils of the leaves. The rather showy white petals are 2-lobed at the summit.

8. ***Silene stellata* (L.) Ait. f. Starry Campion**
Map 940

Silene stellata var. *scabrella* (Nieuwland) Palmer & Steyer. [BB]

Silene stellata var. *stellata* [BB]

Flowers June–September.

Occurs in usually dry upland woods or wooded slopes, rarely in clearings or along railroads. Throughout Missouri and doubtless in every county.

Ranges from Massachusetts to Minnesota, south to Georgia, Alabama, Arkansas, Oklahoma, and Texas.

By some authors the Missouri material would be placed in var. *scabrella*, distinguished from typical var. *stellata* by the densely puberulent instead of glabrous calyx and pedicels, the slightly stouter pedicels, and the calyx 10 mm. instead of 8 mm. long.

938 *Silene cucubalus* var. *cucubalus* (Bladder Campion)939 *Silene nivea* (Snowy Campion)940 *Silene stellata* (Starry Campion)

9. ***Silene noctiflora* L.** Night-flowering Catchfly
Map 941

Flowers May–September.

Occurs in waste and cultivated ground, along roadsides and railroads.

Scattered in central and southwestern Missouri, in St. Louis, Franklin, Boone, Saline, and Jasper counties.

Native of Europe; introduced and naturalized in south Canada and much of the United States south to Florida, Missouri, Utah, and Washington.

This has been mistaken for *Lychnis alba*, a frequently encountered species and much more common in Missouri than *Silene noctiflora*. The main distinguishing characters between these species were indicated under *Lychnis alba*.

10. ***Silene caroliniana* Walt. var. *Wherryi* (Small)**
Fern. Wild Pink Map 942

Silene Wherryi Small [P & S, Steyermark.]

Silene caroliniana subsp. *Wherryi* (Small) Clausen [BB]

Flowers April–May.

Occurs in acid soils of rocky upland woods in chert and Roubidoux sandstone soils, and on ledges and bluffs of Roubidoux sandstone, chert, or flint outcrops. Known only from a limited section of the Ozark region bounded by Crawford, Dent, Shannon, Phelps, Pulaski, Laclede, Texas, and Douglas counties.

Ranges in Ohio, Kentucky, Alabama, and Missouri.

This is one of the most beautiful wildflowers in Missouri. It favors acid soils in rocky upland woodland. The ascending or somewhat spreading stems arise from a rosette of pale green leaves. Sometimes a single plant may produce 50–100 showy rosy-pink flowers.

The plant may be successfully grown in a wildflower rock garden if provided with ample drainage, acid rocks, and some shade. Plants are often found with their roots entangled only in a loose mass of chert and flint rocks. If the roots are not disturbed in transplanting, and an environment created similar to the one the plant came from, the chances for success are good in naturalizing this plant. Several plants have prospered during the past fifteen years in the author's wildflower garden in northern Illinois.

11. ***Silene virginica* L.** Fire Pink Map 943
Flowers April–June.

Occurs in rocky woods, ledges, and wooded slopes in sandstone, chert, granite, or limestone soils. Restricted to the Ozark section of southern and east-central Missouri, north to Jefferson, Washington, Crawford, Miller, Laclede, Greene, Lawrence, and Newton counties, and in the Ozark area of Montgomery County.

Ranges from New York and Ontario to Minnesota, south to Georgia, Alabama, Arkansas, and Oklahoma.

This showy-flowered species is common in the Ozark section and adapts itself easily to wildflower gardens, preferring a semi-shaded, well-drained situation. It does well on shaded rock ledges.

11a. ***Silene virginica* × *Silene caroliniana* var. *Wherryi***
Map 943

This hybrid is known only from Shannon County (upland chert woods, 3 mi. south of Dent-Shannon Co. line, in Shannon Co., May 11, 1935, *Steyermark 18923* and *18924*). Both parent species were present, represented by *S. virginica* (*Steyermark 18921*) and *S. caroliniana* var. *Wherryi* (*Steyermark 18922*). Number *18923* had the shape of the petals of *S. virginica*, but an

PLATE NO. 160

942 *Silene caroliniana* var. *Wherryi* (Wild Pink)

943 • *Silene virginica* (Fire Pink)
943 x *Silene virginica* x *Silene caroliniana* var. *Wherryi*

intermediate color between pink and red, with the pink predominating. Collection number 18924 had the red petals of *S. virginica*, but the stature of the plant and shape of the petals of *S. caroliniana* var. *Wherryi*.

12. ***Silene regia* Sims** Royal Catchfly Map 944
Flowers late May (May 30, 1879, St. Louis Co., Letterman) – October.

Occurs on rocky prairies, rocky open woods, thickets, and borders of rocky glades. Restricted to the Ozark section of southern and east-central Missouri, north to St. Louis, Franklin, Maries, Cole,

Laclede, Polk, Cedar, and Jasper counties.

Ranges from Georgia to Louisiana and Oklahoma, north to Ohio, Indiana, Illinois, and Missouri.

The striking crimson-scarlet or bright red flowers are among the reddest of any wildflowers in Missouri, rivaling or surpassing those of Cardinal Flower (*Lobelia cardinalis*) in intensity. The author has grown the species in his wildflower garden in northern Illinois from seed, as well as having successfully transplanted individuals which have maintained themselves and seeded new plants during the past fifteen years. The species has a long flowering season and produces flowers well up to frost in northern Illinois.

13. ***Saponaria* L.**

Leaves narrowed at the base; calyx not winged, cylindrical with curved or rounded sides, 20-nerved; flowers in dense clusters at the top and sides of the stem; perennial with dull or dark green leaves, not glaucous (no bloom that can be rubbed off) 1. *S. OFFICINALIS*

Leaves rounded and clasping at the base; calyx conspicuously 5-angled and in winged fruit, ovoid, 5-ribbed; flowers in a loosely branched inflorescence at the top of the stem; annual with pale or blue-green leaves with a glaucous 'bloom' which can be rubbed off. 2. *S. VACCARIA*

1. ***Saponaria officinalis* L.** Bouncing Bet
Map 945

Also known as Soapwort.
Flowers June–October.

Commonly found on gravel and sand bars along streams, roadsides, railroads, fallow fields, sandy or open waste ground, and rarely in wooded areas. Throughout Missouri, doubtless in every county.

Native of Europe; introduced and naturalized throughout North America.

This species was formerly cultivated as a garden plant, but has become well established as a weed. The deliciously spicy-fragrant pink-lilac to whitish flowers are either single or double. A soapy green lather can be made from the plant by rubbing the leaves and stems in some water. The juice of the plant

is reputed to be slightly poisonous as in the following species, *S. Vaccaria*.

2. ***Saponaria Vaccaria* L.** Cow Herb Map 946

Also known as Cow Soapwort, Cow Cockle.

Vaccaria segetalis (Neck.) Garcke [BB]

Vaccaria vulgaris Host [Small]

Vaccaria pyramidata Moench [Royal Hort. Dict., Shinnery]

Flowers late May–September.

Occurs along railroads and roadsides. Scattered in southern, central, and eastern Missouri; not recorded from the northwestern third of the state, but to be expected throughout most of the counties.

Native of Europe; introduced and naturalized throughout the greater part of North America.

The flowers vary from deep pink to pale pink, the latter color sometimes recognized as var. *rosea* Hort., and white-flowered individuals as var. *alba* Hort. The seeds contain a toxic substance which sometimes poisons poultry, rabbits, and other animals in screening of grain containing some of the seeds.

Other species of *Saponaria* are cultivated as garden plants. A trailing, much branched, pink-flowered

species with small leaves, *S. ocymoides* L., is frequently found in gardens. There is no definite record of its having become established outside of gardens. A specimen from Platte County in the herbarium of Park College (Weatherby Lake, on dam, 1½ mi. north of Parkville, May 9, 1957, *Kent Drew 91*) was collected, so far as known, from a planted clump.

14. **Dianthus** L. Pink, Carnation

All the species of *Dianthus* found in Missouri are of European origin. Some species, such as *D. plumarius* L., not here included, may eventually be found as escapes from cultivation.

- a. Leaves 10–18 mm. broad, lanceolate to elliptic-oblong 2. *D. BARBATUS*
- a. Leaves 1.5–8 mm. broad, linear or linear-lanceolate *b*
- b. Calyx tube with 5 to 15 nerves 4. *D. PROLIFER*
- b. Calyx tube with 20–40 nerves *c*
- c. Each flower solitary on its own single long stalk of 1–4 cm. length; leaves of stem 1–4 cm. long; stem glabrous or with short hairs; calyx with 30–40 nerves; low perennial with trailing leafy shoots, forming loose mats, 1–4 dm. tall. 1. *D. DELTOIDES*
- c. Inflorescence consisting of few or several closely crowded flowers in clusters, the flowers without stalks or nearly so; leaves of stem 2–8 cm. long; stem more noticeably hairy; calyx with 20–25 nerves; annual or biennial plant with erect stem 2–8 dm. tall, and without any trailing leafy shoots, not forming loose mats 3. *D. ARMERIA*

- 1. **Dianthus deltoides** L. Maiden Pink Map 947
Flowers May–August.
Known only from Franklin County, east-central Missouri, where escaped from gardens.
Native of Europe; naturalized in the United States from New Hampshire to Michigan, south to New Jersey, Illinois, and Missouri.
- 2. **Dianthus barbatus** L. Sweet William
Map 948
Flowers June–August.
Known only from Jasper County, southwestern Missouri, where escaped from gardens (waste ground near Webb City, June 16, 1923, *Palmer 23314* in *Palmer herb.*).
Native of Europe; naturalized in North America

- from Quebec to North Dakota, south to Delaware and Missouri.
- 3. **Dianthus Armeria** L. Deptford Pink Map 949
Flowers late May–October.
Occurs in open woodland, along roadsides, railroads, waste ground, fields, and pastures. Throughout Missouri; not recorded from a number of northern Missouri counties, but doubtless to be found there.
Native of Europe; introduced and naturalized in North America from Quebec and Ontario, south to Georgia, Kentucky, Missouri, and Oklahoma.
- 4. **Dianthus prolifer** L. Map 950
Tunica prolifera (L.) Scop. [BB]
Flowers May–October.

947 *Dianthus deltooides* (Maiden Pink)

948 *Dianthus barbatus* (Sweet William)

949 *Dianthus Armeria* (Deptford Pink)

Known only in Stone County, southwestern Missouri (dry open rocky places near pasture above gravel bar along Big Creek, about $\frac{1}{2}$ mi. northwest of junction with White River, T22N, R24W, NE sect. 18, NW sect. 17, $5\frac{1}{2}$ mi. southeast of Shell Knob, July 13, 1956, *Steyermark 81924*).

Native of Europe; introduced and naturalized in the United States from New York to South Carolina,

Kentucky, Ohio, Missouri, Oklahoma, and California.

The station from which this plant was collected is now destroyed and part of the lake bottom of the impoundment of Table Rock Dam on White River. Presumably, careful search will reveal its presence in other, possibly southern, sections of the state.

Order **RANALES**

Fam. **CERATOPHYLLACEAE** (Hornwort Family)

Ceratophyllum L. Hornwort

For a detailed discussion, the reader is referred to the most recent revision of this genus by Norman C. Fassett (North American *Ceratophyllum*, in *Comunicaciones del Instituto de Investigaciones Cientificas*, Universidad de El Salvador no. 2: 25-45. March, 1953).

Leaves forked 1-2 times, or simple and not forked; teeth on the leaf-divisions arising from a broad green base connected with the leaf; fruit not winged, with 1 long spine at one end and 2 spines at the other basal end; common type found in Missouri 1. *C. DEMERSUM*

Leaves forked 2-4 times; teeth on the leaf-divisions arising directly from the main leaf-division with little or no green base connecting the teeth to the leaf-division; fruit narrowly winged, sometimes also with spines along the margins; rarer type found 2. *C. ECHINATUM*

- 1. **Ceratophyllum demersum** L. Coontail,
Hornwort Map 951
Flowers July-October.

Occurs in sluggish streams, sloughs, artificial and natural ponds, oxbow lakes of river bottom, and in slow water of spring branches. Mainly in southern and central Missouri north to St. Charles, Boone, Macon, Saline, Carroll, Clay, Platte, and Buchanan counties; absent or not recorded from most of northern Missouri.

Ranges from Quebec to British Columbia, and in most of the United States, south to Mexico, Central and South America, and the West Indies; also in Europe and Asia.

The seeds of this species and, sometimes, the foliage, constitute a food item of importance to wild-fowl. The large branching masses of leaves and stems afford a good shelter for young fish and small invertebrate animals, and serve as a habitat for many aquatic insects eaten by fish.

Plate no. 161. 1. *Saponaria Vaccaria*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden. 2. *Dianthus deltooides*, $\times \frac{2}{5}$. 3. *Dianthus Armeria*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden. 4. *Dianthus barbatus*, $\times \frac{2}{5}$. 5. *Dianthus prolifer*, $\times \frac{2}{5}$; After Gleason, The New York Botanical Garden. 6. *Ceratophyllum demersum*, $\times \frac{2}{5}$; Details from Small, The New York Botanical Garden.

PLATE NO. 161

PLATE NO. 161

950 *Dianthus prolifer*

951 *Ceratophyllum demersum* (Coontail)

952 *Ceratophyllum echinatum* (Coontail)

The plants vary considerably in aspect, having soft or stiff and hard foliage, dark green or sometimes dull bronze, or lighter green tinged with reddish-brown. The leaves vary from slender to thickish and from short leaves only 3–5 mm. long to longer ones 7–22 mm. long. It is one of the more characteristic plants found in the fresh water springs of the Ozarks, ranking ninth in frequency of species encountered (Steyermark, Bot. Ser. Field Mus. Nat. Hist. 9, no. 6: 493. 1941). In these springs or spring branches it favors the deeper and more quiet waters with a muddy substratum.

Ceratophyllum demersum may sometimes be confused with the superficially similar *Myriophyllum*, *Chara*, and *Nitella*. From *Myriophyllum* it may be distinguished by the forking and branching leaves with teeth or irregularities on the margins of the leaf-divisions as contrasted with the pinnately parted leaves of *Myriophyllum* with no teeth or irregularities on the leaf-divisions. Both *Chara* and *Nitella* pertain to the Characeae of the algae, whose leaflike divisions are only elongated narrow cells unlike the multicellular leaf tissue of a leaf segment of *Ceratophyllum* or other spermatophytes.

2. ***Ceratophyllum echinatum*** Gray Coontail, Hornwort Map 952
Flowers July–October.

Occurs in natural oxbow lakes of river bottom, upland sink-hole ponds in the Ozarks, and in sluggish waters of slow streams and ponds. Known only from five counties in southern and east-central Missouri northeast to St. Charles County. The following two collections have been seen by the present author and verified by Dr. Fassett: St. Charles County (Merry Rundo Lake, 5 mi. north of St. Peters, October 5, 1933, *Steyermark 8864* in herb. Univ. of Mo.); Oregon County (in 2–3 feet of water, Red Brush Pond, T24N, R2W, sect. 16, 4 mi. south of Wilderness, July 20, 1936, *Steyermark 12072*).

Ranges from Florida to Texas and Mexico, north to Maine, Quebec, New York, Ohio, Michigan, Wisconsin, Missouri, and Kansas.

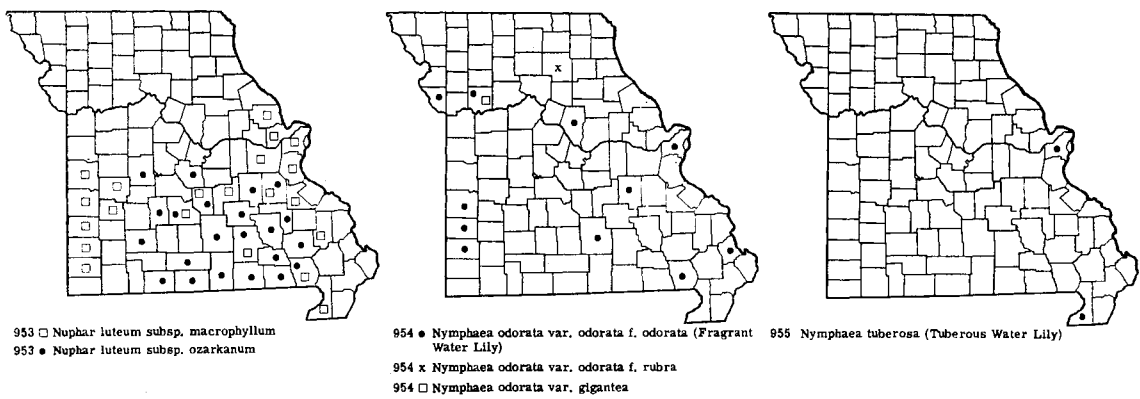

This species, according to Dr. Fassett's studies, does not show the variability as exhibited by *C. demersum*. The leaves are more uniform in length, 17–21 mm. long with slender terminal segments 0.1–0.2 mm. wide.

Fam. **NYMPHAEACEAE** (Water Lily Family)

- a. All the submerged leaves deeply and finely dissected 5. CABOMBA
- a. None of the leaves dissected. b
- b. Leaves split or cleft at one end, the leaf-stalk (petiole) joining the leaf-blade at the base of the cleft (sinus) c
- c. Most of the main nerves of the leaf-blade unbranched or forking only near the leaf-margin and spreading directly from the main midrib; flowers yellow, with small, thick, stamen-like petals 6–9 mm. long; the 5, 6, or more sepals are yellow or tinged red or green, and roundish; floating or aerial leaves oval 1. NUPHAR
- c. Main nerves of the leaf-blade much branched and forked and at least half of them originating directly from the top of the petiole (main leaf-stalk); flowers white, pink, or rose, with showy colored petals mostly 45–90 mm. long, and not stamen-like; the 4 sepals are green or purplish tinged on outside, and oblong-lanceolate; floating leaves round or nearly so 2. NYMPHAEA
- b. Leaves entire, not split nor cleft at any place, the leaf-stalk (petiole) joining the leaf-blade approximately at the middle of the blade. d

1. **Nuphar** Sm. Yellow Pond Lily, Spatterdock, Yellow Water Lily

The underground rootstock in these two subspecies of *Nuphar* is very thick and spongy, at least 5 cm. thick, and bears prominent circular scars of the remains of the flower-stalks and semicircular scars of the remains of the leaf-stalks.

2. *Nymphaea* L. Water Lily

- a. Petals, or at least the outer ones, rose-colored or pink 1b. *N. ODORATA* var. *ODORATA* f. *RUBRA*
- a. Petals white b
- b. Flowers very fragrant, mostly 5–12 cm. across (10–20 cm. in var. *gigantea*); petals with tapering ovate obtuse tip; lower surface of leaves purple or purple-red; petiole (leaf-stalk) not striped; inner filaments narrower than anthers 1a. *N. ODORATA* var. *ODORATA* f. *ODORATA*
- b. Flowers not fragrant or with a faint scent, 10–25 cm. across; petals with a broadly rounded summit, obovate or spatulate; lower surface of leaves mainly green; petiole (leaf-stalk) green, striped above with brown; filaments broader than anthers 2. *N. TUBEROSA*

1. *Nymphaea odorata* Ait. Fragrant Water Lily
Map 954

Flowers late May–September.
Occurs in ponds and sloughs.
The following variations are found in Missouri:

- a. Petals, at least the outer ones, rose-colored or pink 1b. *N. ODORATA* var. *ODORATA* f. *RUBRA*
- a. Petals white b
- b. Flowers mostly 5–12 cm. across; sepals 2.8–8 cm. long, 1–2.5 cm. broad; leaves not turning upward at the edge
- 1a. *N. ODORATA* var. *ODORATA* f. *ODORATA*
- b. Flowers 10–20 cm. across; sepals 5–10 cm. long, 2.4–3.6 cm. broad; leaves (when growing) turning upward at the edge
- 1c. *N. ODORATA* var. *GIGANTEA*

1a. *Nymphaea odorata* var. *odorata* f. *odorata*
Map 954

Nymphaea odorata Ait. [G, P & S, Steyermark.]
Nymphaea odorata var. *odorata* [BB]
Scattered and rare in southern and central Missouri north to St. Louis, Boone, Ray, and Platte counties. Ranges from Newfoundland to Manitoba, south to Florida, Louisiana, and Texas.

1b. *Nymphaea odorata* var. *odorata* f. *rubra*
Guillon
Map 954

Nymphaea odorata f. *rubra* Guillon [G]
Known only from Macon County in northern Missouri (Ethel Lake, T59N, R17W, south part sect. 25 and north part sect. 36, $\frac{3}{4}$ mi. west of Ethel, September 14, 1954, *Steyermark 77311*).
This was introduced from plants purchased from a Chicago company fifteen years ago and is well established in the lake.

1c. *Nymphaea odorata* var. *gigantea* Tricker
Map 954

Nymphaea odorata var. *villosa* Caspary [Shinners]
Known from Ray County, west-central Missouri. Ranges from Florida to Texas and Mexico, north to Massachusetts, Illinois, Missouri, and Oklahoma. As in *Nuphar lutea*, the underground rootstock is thick and spongy, at least 5 cm. thick, and bears prominent semi-circular and circular scars.
The flower buds of *N. odorata* are sometimes cooked as a vegetable by the northern Ojibwa Indians.

2. *Nymphaea tuberosa* Paine Tuberous Water Lily
Map 955

Plate no. 162. 1. *Nuphar luteum* subsp. *macrophyllum*, $\times \frac{2}{7}$. 2. *Nuphar luteum* subsp. *ozarkanum*, $\times \frac{2}{7}$. 3. *Nelumbo lutea*, $\times \frac{2}{7}$; After Britton and Brown, The New York Botanical Garden. 4. *Nymphaea odorata* var. *odorata*, $\times \frac{2}{7}$. 5. *Cabomba caroliniana*, $\times \frac{2}{7}$. 6. *Brasenia Schreberi*, $\times \frac{2}{7}$. Details from Small, The New York Botanical Garden.

PLATE NO. 162

956 *Nelumbo lutea* (American Lotus)957 *Nelumbo nucifera* (Sacred Lotus)958 *Brasenia Schreberi* (Water-shield)

Flowers June–October.

Occurs in ponds and slow streams.

Known only from eastern Missouri in St. Louis (Natural Bridge road, June 17, 1893, *Eggert*) and Dunklin (St. Francis River, Bertig, September 28, 1897, *Trelease 11*) counties.

The St. Louis County record, so far as known, is now exterminated, and there is no collection of the species since the one by *Trelease* in 1897.

Ranges from Quebec to Ontario, Minnesota, and Nebraska, south to Maryland, Ohio, Indiana, Illinois,

Missouri, and Arkansas.

The dormant tuberous branches of the rootstock of some of the African species of *Nymphaea* are starchy and are boiled or roasted, while the kernels are cooked whole or ground into a flour. The brown tubers of the rootstock of *N. tuberosa* probably possess similar human food value. The rootstocks of *N. tuberosa* and *N. odorata* are eaten by beavers, muskrat, and deer, while the seeds are eaten by various wildfowl. The leaves provide shade and shelter for fish.

3. *Nelumbo* Adans.

Flowers pale yellow; petiole (leaf-stalk) and peduncle (flower-stalk) rather smooth and glabrous . 1. *N. LUTEA*
Flowers pink or rose-colored; petiole (leaf-stalk) and peduncle (flower-stalk) rather rough . . . 2. *N. NUCIFERA*

1. *Nelumbo lutea* (Willd.) Pers. American Lotus Map 956

Also called Yanquapin, Water Chinquapin, Lotus Lily.

Flowers late June (June 25)–September.

Occurs in oxbow lakes and ponds in river flood plain, upland sink-hole ponds, artificial lakes and ponds, and sloughs. Throughout Missouri, commonest and in greatest abundance in oxbow lakes in the flood plain of the Mississippi and Missouri rivers and their tributaries, especially the Grand, Chariton, Mussel Fork, Thompson, Osage, Mariais des Cygnes, and South Grand rivers.

Ranges from Florida to Texas, north to Massachusetts, New York, Ontario, Minnesota, and Iowa.

For an interesting account of the species, the reader is referred to the article by Thomas F. Hall and Wm. T. Penfound in *Am. Midl. Nat.* 31: 744–58. 1944.

The American Lotus was extensively used by the American Indian for food. The starchy tuberous enlargements of the rootstock, produced in autumn, when baked, make a palatable dish, as do the young

leaf-stalks and young leaves when cooked as a vegetable. The seeds have a chestnutlike flavor if eaten in the earlier stage before the shell gets hard, while the kernel of the ripe seeds, after having been removed from the hard shell by parching, is cooked or ground up for breadstuff.

The roots are eaten by beaver and the seeds are eaten by some wildfowl.

The seeds possess unusual powers of longevity and dormancy, records showing seeds germinating following a dormant period of at least 200 years. The late Mr. John Kellogg of the Missouri Botanical Garden related to this author that he had seen seeds of Yanquapin, which had previously occupied some of the Fox River bottoms near Allenton, germinate 40 years later when the abandoned fields containing the seeds were newly plowed for cultivation.

The underground rootstock is 1 cm. or less thick in contrast to the much thicker (5 cm. and more) rootstocks of *Nuphar* and *Nymphaea*. The large blue-green leaves possess the character, as in Touch-me-not (*Impatiens capensis* and *pallida*) and a few other native

plants, of shedding water when held below the surface of the water. The plants are quite ornamental, and the large leaves afford shelter and habitats for wildlife, and attract marsh birds and wildfowl. The large leaves act as a shelter and shade for fish.

2. **Nelumbo nucifera** Gaertn. Sacred Lotus
Map 957
Also known as East Indian Lotus.

Flowers late June–August.
Introduced into lakes, where established in Iron (Iron Mountain Lake, July 23, 1932, *Kellogg 26126*) and Platte (Basswood Lakes, 4 mi. east of Platte City, July 12, 1956, *Radloff*) counties.
Native of Asia and Australia.
The seeds and rootstocks are used for food in southern China, where the species is cultivated.

4. **Brasenia** Schreb. Water-shield

Brasenia Schreberi Gmel. Water-shield Map 958
Flowers May–September.
Occurs in natural and artificial ponds and sloughs. Scattered in Missouri, mainly in the southern third of the state, north locally in Harrison County.
Ranges from Central America, the West Indies, and Mexico, north from Florida to Texas, north to Nova Scotia, Ontario, Minnesota, Nebraska, Manitoba, British Columbia, and Oregon; also in Asia, Africa, and Australia.

The gelatinous covering of the stems, young buds, and lower leaf surface readily identifies this species. All the leaves are floating in this plant. It is of food value to ducks, and the tuberous roots are reported to be eaten by Indians in California. The young leaves and petioles, before the gelatinous covering is prominent, are also reported as eaten as a salad by some of the Japanese. In its natural haunts the leaves afford shade and shelter for fish.

5. **Cabomba** Aubl. Fanwort, Carolina Water-shield

For a recent revision of the genus, the reader is referred to Norman C. Fassett, *A Monograph of Cabomba* (*Castanea* 18: 116–28, 1953).
Cabomba caroliniana Gray Fanwort Map 959
Flowers May–September.
Occurs in swamps, sloughs, and introduced occasionally into ponds. Rare and scattered in eastern Missouri from St. Charles County south; most common in the lowlands of southeastern Missouri and along swamps in the flood plain near the junction of the Missouri and Mississippi rivers.
Ranges from Florida to Texas, north to Massachusetts, New York, Kentucky, Michigan, Illinois, and

Missouri; considered to be introduced in the Atlantic states north of Virginia.
The flowers are rather showy, 1.2–1.8 cm. broad, white with yellow spots at the base, rising above the water on long stalks. The plant is considered to be of slight food value to water birds, but is a valuable food producer and cover for fish. The decorative dark green fan-shaped leaves are often seen in fresh water aquaria as an ornamental aquatic plant.

Fam. **MAGNOLIACEAE** (Magnolia Family)

Leaves longer than broad, not toothed or lobed, with only 1 tip 1. **MAGNOLIA**
Leaves about as broad as long, with 4–6 lobes, the tip spreading into 2 points 2. **LIRIODENDRON**

1. **Magnolia** L. Magnolia

Magnolia acuminata L. var. **acuminata**
Cucumber Tree Map 960
Magnolia acuminata var. *ozarkensis* Ashe [P & S, Steyer.]
Magnolia acuminata L. [G, BB, P & S, Steyer.]
Flowers April–May.
Occurs in low woods in valleys of streams in the southwestern Ozarks, at the base of wooded limestone

959 *Cabomba caroliniana* (Fanwort)960 *Magnolia acuminata* var. *acuminata* (Cucumber Tree)961 *Liriodendron Tulipifera* (Tulip Tree)

and gravel bluffs and thickets along the Mississippi River, and in gravelly or clayey soil of low wooded hills of Crowley Ridge in southeastern Missouri. Restricted to extreme southern Missouri, in two areas: (1) southeastern Missouri along Crowley Ridge in Dunklin, Butler, Stoddard, and Scott counties and northeast along the Mississippi River to Cape Girardeau County; (2) southwestern Missouri, along the White River and North Fork of White River in Ozark, Taney, and Barry counties. The latter stations have now been exterminated by the creation of the Bull Shoals and Table Rock dams, since the trees had occupied the low valleys of these areas.

Ranges from Georgia to Louisiana and Oklahoma, north to New York, Ontario, Ohio, Indiana, Illinois, and Missouri.

Magnolia acuminata var. *ozarkensis*, separated from typical *M. acuminata* var. *acuminata* on the basis of having the lower surface of the leaf-blades green and completely glabrous or slightly hairy on the veins instead of pale green and pubescent on the lower surface, does not appear to be sufficiently constant in these characters to merit recognition as formerly was accorded it and as later field studies seem to bear out.

The flowers, 6–8 cm. long, have six petals, of which the outer three are glaucous-green tinged with yellow, the inner three yellow in the upper half and green in the lower half; the styles are yellow and the receptacle green. The fragrance of the flowers resembles that of daffodils. In autumn the foliage takes on a greenish-yellow or dull yellow color. The seeds of the cucumberlike green cones of the tree are quite bitter and are not eaten by birds and fur-bearing animals, but the green cones were at one time eaten by early pioneers after the bitter properties had been extracted. After being mashed up and placed in whiskey, the green cones are sometimes used to make a mildly bitter medicine.

The tree is used in the lumber industry for flooring,

cabinetmaking, interior finish, barrels, boxes, and crates, and in mixture with other hardwoods the wood is pulped for paper making.

In the Trail-of-Tears State Park in Cape Girardeau County there are many magnificent specimens of the tree, and it is sometimes cultivated as an ornamental shade tree because of its rapid growth. It can be grown throughout Missouri.

Excluded Species

***Magnolia tripetala* L. Umbrella Tree**

There are no valid records for the occurrence of this species in Missouri. It has been reported from Missouri in the eighth edition of *Gray's Manual* (p. 676), as well as in the previous edition of that manual. This report may possibly have been based upon a specimen labeled by Eggert on May 9, 1898 from 'Normandy?' recopied to read 'Normandy.' As Eggert collected *Magnolia tripetala* on the same day (May 9, 1898) in Franklin Co., Tennessee, his specimen from Normandy undoubtedly referred to Normandy in Bedford Co., Tennessee, which is close to Franklin Co. and not Normandy in St. Louis County, Missouri. It would have been possible in 1898 for Eggert to have been in Franklin and Bedford counties, Tennessee, on the same day, but the slow transportation and poor roads would have prevented his being in Franklin Co., Tennessee and St. Louis Co., Missouri on the same day. Eggert, who often collected in St. Louis County, Missouri, occasionally neglected, as have other collectors in other places, to cross out 'Missouri' from the top of the label, which he ordinarily used, when collecting in other states.

The nearest stations to Missouri for this species are in Pope County, Arkansas, about 75 miles south of the Missouri border.

2. **Liriodendron** L. Tulip Tree**Liriodendron Tulipifera** L. Tulip Tree,

Yellow Poplar Map 961

Also known by other names, such as Whitewood, Canoe-wood, White Poplar, Poplar, and Hickory Poplar.

Flowers May-June.

Occurs in rich woods of ravines, in upland woods and along streams of Crowley Ridge, and at the base of wooded bluffs along the Mississippi River. Southeastern Missouri north to Bollinger and Perry counties and west to Wayne and Butler counties. Reported from Madison, Ripley, and Oregon counties by Transeau (Ecol. 16: 430, fig. 15. July, 1935), but the records have not been substantiated by herbarium specimens. Reported also as escaped from cultivation in St. Louis County.

Ranges from Florida and Louisiana, north to Massachusetts, Vermont, New York, Ontario, Michigan, Indiana, southern Illinois, and Missouri.

In southeastern Missouri this is often associated with beech and cucumber tree, as well as with sugar maple, white oak and other species. It is a tree of the richer and well-drained soils. It is widely planted in

St. Louis and other cities and towns of Missouri. The flowers, growing erect at the tip of the leafy branches, are often missed when the tree is in bloom, but are quite showy. They are slightly fragrant and the 6 petals of the tulip-shaped, cuplike flower (the state flower of Indiana) are greenish-yellow with a bright orange color inside near the base. The foliage turns yellow to orange-yellow in autumn.

The tulip tree grows taller than any other hardwood tree in North America, reaching a height of 200 feet in some areas of the eastern United States. The wood, which is one of the lightest North American woods known, and the softest of the hardwoods, is used for many purposes, including insulating material, exterior and interior finish of houses, boatbuilding, shingles, brooms, woodenware, hat blocks, crates, boxes, and millwork. Mixed with other hardwoods, it is also used as pulp for papermaking. Early pioneers also used it for canoes, furniture, and general construction. The bitter inner bark of the roots was formerly used in medicine as a tonic and stimulant, and an alkaloidal substance, extracted from the bark, was used as a heart stimulant.

Fam. **ANNONACEAE** (Custard Apple Family)**ASIMINA** Adans. Pawpaw**Asimina triloba** (L.) Dunal Pawpaw Map 962

Flowers March-May.

Occurs in low bottom woods and wooded slopes along streams, ravines, and at the base of bluffs. Throughout Missouri; absent from the extreme northern counties, and found north to Clark, Shelby, Macon, Linn, Grundy, Daviess, De Kalb, Andrew, and Atchison counties.

Ranges from Florida to Texas, north to New Jersey, New York, Ontario, Michigan, Illinois, southern Iowa, and southeastern Nebraska.

The tree sends up suckers from the roots, forming groves or thickets. The foliage remains green long after other trees have changed colors in autumn, but eventually turns greenish-yellow to yellow before falling late in autumn.

The sweet fruits, which ripen during September, long before touched by any frost in Missouri, resemble small stout bananas about 7-12.5 cm. ($2\frac{3}{4}$ -5") long. They are good to eat when just beginning to feel soft to one's touch. At first the thin covering of the fruit

is pale green, but eventually turns brown to black when over-ripe. The flesh of the fruit, at first creamy white, becomes pale yellow, resembling egg-custard, and has a sweet flavor. The fruits are eaten raw or may be made into an ice cream, sherbet, pudding, pie, jelly, or combined with 'Jello,' eggs, and cornstarch for a dessert. Some people are allergic to the fruits and develop a dermatitis after handling or eating them. The trees are difficult to transplant, but are easily grown from seed. Plants, started from seed at the author's botanical preserve in northern Illinois, did not begin to flower until after twelve years' growth, but farther south in Missouri should start flowering much earlier. The large, long, drooping dark green leaves are quite ornamental in appearance.

A strong alkaloid contained in the seeds has a depressing effect on the brains of animals, although the fruit is relished by such fur-bearers as opossum, raccoon, and gray squirrels. The bark, which is difficult to tear, strips off into long pieces, and was used by some early pioneer fishermen for stringing fish.

The inner bark was woven into a cloth by Indians of Louisiana. In this connection it is interesting to note that the similar difficult-to-tear properties of the bark

of some tropical Venezuelan trees of this family serve the Indians of that country as substitutes for rope and head-strap carriers or tumplines.

Fam. **RANUNCULACEAE** (Crowfoot Family)

- a. Plants mainly submerged in the water with finely divided foliage 9. **RANUNCULUS**
- a. Plants mainly growing out of the water, or on rocks, or in soil b
- b. Some or all of the leaf-blades, main leaf-stalks (petioles) of the leaves, or leaf-like bracts of the involucre opposite each other on the stem in 2's or in whorls (circles) of 3 or more c
- c. Stems climbing, vining, or sprawling 15. **CLEMATIS**
- c. Stems not climbing, vining, nor sprawling d
- d. Leaves opposite each other on the stem in 2's 15. **CLEMATIS**
- d. Leaf-like bracts of the involucre (which resemble leaves) in whorls (circles) of 3 or more e
- e. Lobes of leaf-like bracts sharply toothed 12. **ANEMONE**
- e. Lobes of leaf-like bracts rounded 14. **ANEMONELLA**
- b. Leaf-blades or the main leaf-stalks (petioles) of the leaves alternate on the stem, or arising from the base of the plant, or both; herbaceous plants f
- f. All the leaves grass-like, linear-spatulate, and arising at the base of the plant; flowers greenish, on a long and slender mousetail-shaped column (receptacle) 10-15 or more times as long as broad 11. **MYOSURUS**
- f. Plants without the above combination of characters g
- g. Flowers with 1 or more spurs (slender tubes or extensions projecting) h
- h. Flowers both red or pink and yellow (rarely completely pale yellow), with 5 spurs; leaves ternately compound, the basal ones with usually 3 long-stalked compound divisions 6. **AQUILEGIA**
- h. Flowers usually blue, purple, white, or mixtures of these, sometimes all pink or rose, with only 1 spur; leaves palmately divided or cut 7. **DELPHINIUM**
- g. Flowers lacking spurs i
- i. Flowers yellow j
- j. Petals not bearing a nectar-pit or scale at the base; petals 6-9; flower solitary, 1 on a stem; leaves dissected into slender segments, sessile on an erect terrestrial stem; pistils hairy 10. **ADONIS**
- j. Petals bearing a nectar-pit or scale at the base; petals mostly 5, usually smooth-edged; flowers 1 or more; leaves, when finely dissected, occurring in the water; pistils usually glabrous 9. **RANUNCULUS**
- i. Flowers of other colors, not yellow, or yellow with purple at base k
- k. Leaves lobed only, not split or divided to the base, nor compound l
- l. Leaves with 3 (rarely 4) smooth-edged (entire) lobes; leaves all arising at the base of the plant 13. **HEPATICA**
- l. Leaves with 5-11 toothed lobes; leaves on the stem as well as at the base of plant m
- m. Leaves 2 on the stem, near the summit; flower 1 on a plant; fruit red, fleshy; rootstock yellow 1. **HYDRASTIS**
- m. Leaves 3 or more on the stem, scattered; flowers several or many on a plant; fruit green to brown, dry; rootstock not yellow 5. **TRAUTVETTERIA**
- k. Leaves split or divided to the base, or compound n
- n. Petals pale yellow with purple at base; leaves scattered and alternate on stem, dissected into numerous narrowly linear segments 10. **ADONIS**
- n. Flowers white, pink, rose, lavender, purplish, or greenish; leaves, if finely dissected, arising mainly from the base of the plant o
- o. Petals or petal-like parts less than 5 mm. long; flowers many, crowded on a simple or branching axis p
- p. Flowers perfect (both stamens and pistils in the same flower), decidedly white, in close clusters; leaflets sharply toothed q

962 *Asimina triloba* (Pawpaw)

963 *Hydrastis canadensis* (Golden Seal)

964 *Cimicifuga racemosa* var. *racemosa* f. *racemosa* (Black Cohosh)

- q. Flowers in a very long, narrow cylindrical spray 15–90 cm. long; plants 1–2.6 m. tall; fruit dry greenish-brown follicles. 2. *CIMICIFUGA*
- q. Flowers in a short dense ovate cluster 3–8 cm. long; plants 0.4–0.8 m. tall; fruit white, fleshy, berry-like 3. *ACTAEA*
- p. Flowers unisexual (either male or female), greenish, whitish or purplish, in loose scattered clusters; leaflets with rounded or blunt teeth 4. *THALICTRUM*
- o. Petal-like parts always obvious, 5 mm. or more long; flowers solitary, 1 or few on the stem 7
- r. Lobes of leaflets or leaf-like bracts of involucre sharply toothed; leaf-like bracts of involucre opposite or in a whorl (circle). 12. *ANEMONE*
- r. Lobes of leaflets or leaf-like bracts of involucre rounded; leaves alternate or leaf-like bracts of involucre in a whorl 5
- s. Leaves on the stem alternate; roots string-like (sometimes with tuber-like thickenings); plant of low or moist ground 8. *ISOPYRUM*
- s. Leaf-like bracts of involucre which resemble the stem-leaves arranged in a whorl (circle); roots a cluster of thickened tubers; plants of dry, rocky, or upland woods 14. *ANEMONELLA*

1. ***Hydrastis* Ellis** Golden Seal

***Hydrastis canadensis* L.** Golden Seal Map 963
Flowers April–May.

Occurs in rich woods, on slopes, in ravines, and on the floor of valley woods and thickets. Not uncommon throughout the Ozark region and central Missouri north to Pike, Shelby, Boone, Howard, Saline, Lafayette, and Clay counties; mostly absent from the unglaciated prairie region of southwestern Missouri.

Ranges from Vermont to Minnesota and Nebraska, south to Georgia, Alabama, Arkansas, Kansas, and Oklahoma.

The roots and sometimes the leaves are used in medicine. The plant is sometimes encountered in large colonies or as scattered clumps. The red berries are very attractive against the leafy background.

2. ***Cimicifuga* L.**

Cimicifuga racemosa* (L.) Nutt. var. *racemosa* f. *racemosa Black Cohosh, Black Snakeroot

Map 964

Cimicifuga racemosa (L.) Nutt. [G, P & S, Steyererm.]
Flowers late May–August.

Occurs in rocky woods and along the base of bluffs. Restricted to the Ozark region of southern and

east-central Missouri north to St. Louis, Washington, Crawford, Texas, Dallas, Greene, and Jasper counties.

Ranges from Massachusetts to New York to Ontario, Ohio, and Indiana, south to Georgia, Tennessee, and Missouri.

The roots have been used in medicine.

3. *Actaea* L. Baneberry

Actaea pachypoda Ell. White Baneberry

Map 965

Also known as Doll's Eyes.
Actaea brachypoda Ell. [P & S]
Actaea alba (L.) Mill. [BB]
 Flowers May-June.

Occurs in deep rich woods and ravines, often on north-facing slopes and at the base of bluffs. Eastern half of Missouri west in the Ozark region to Moniteau, Camden, Dallas, Greene, Christian, and Barry counties, and in northern Missouri west to Livingston, Holt, and Atchison counties.

Ranges from Quebec to Ontario, Minnesota, and Manitoba, south to Georgia, Alabama, Louisiana, and Oklahoma.

The rhizomes of this species have medicinal properties. The fruit of the related *A. rubra* (Ait.) Willd. is poisonous, while the rootstock of that species has strong purgative and emetic properties. Cases of poisoning to children have been ascribed to a related European species, *A. spicata*, from eating the fruit, and this species is reported as having injurious effects on the heart.

4. *Thalictrum* L. Meadow Rue

- a. Middle and upper stem-leaves with a long petiole (main leaf-stalk) attaching the compound leaf to the main stem; flowering in April and early May; plants generally 3-6 dm. tall; leaflets (leaf-divisions) thin, usually not longer than broad. 1. *T. dioicum*
- a. Middle and upper stem-leaves sessile, the three main divisions of the compound leaf directly attached to the stem without a common petiole; flowering after mid-May; plants generally 6-20 dm. tall; leaflets (leaf-divisions) thicker, usually averaging longer than broad b
- b. Lower leaf-surface or veins or pistils more or less dotted with minute, round sessile glands or gland-tipped, short-stalked hairs 3a. *T. revolutum* f. *revolutum*
- b. Lower leaf-surface or veins or pistils either glabrous (without hairs) or with fine hairs lacking glands on tip c
- c. Lower leaf-surface with fine hairs 2a. *T. dasycarpum* var. *dasycarpum*
- c. Lower leaf-surface glabrous (without hairs) d
- d. Leaf-divisions rather thick, with revolute (rolled under) margins, the veins on lower surface prominent and forming a conspicuous network. 3b. *T. revolutum* f. *glabrum*
- d. Leaf-divisions comparatively thin, with flat margins, the veins on lower surface not prominent nor forming a conspicuous network 2b. *T. dasycarpum* var. *hypoglaucum*

1. *Thalictrum dioicum* L. Early Meadow Rue
 Map 966

Also called Quicksilver Weed.
 Flowers early April-early May.

Occurs usually on rich north-facing wooded slopes and ledges, mostly in the vicinity of limestone rock

outcrops. Mainly in the Ozark section of southern and central Missouri north to St. Louis, Franklin, Maries, Morgan, Benton, and St. Clair counties, north locally in Jackson and Adair counties.

Ranges from Georgia, Kentucky, Alabama, and Missouri, north to Quebec, Ontario, Minnesota,

968 • *Thalictrum revolutum* f. *revolutum* (Wax-leaved Meadow Rue)969 *Trautvetteria caroliniensis* (False Bugbane)970 • *Aquilegia canadensis* f. *canadensis* (Columbine)968 □ *Thalictrum revolutum* f. *glabrum*970 □ *Aquilegia canadensis* f. *flaviflora*

North Dakota, and Manitoba.

The gray-green fernlike foliage is quite decorative. As it persists during the often dry summer and autumn months, it makes a good ground cover or permanent green foliage understory in the shaded wildflower garden.

- 2a. ***Thalictrum dasycarpum*** Fisch. & Lall. var. ***dasycarpum*** Purple Meadow Rue Map 967
Thalictrum dasycarpum Fisch. & Lall. [G, BB, P & S, Steyer.]

Flowers late May–July.

Occurs in low damp ground in wooded valleys and ravines, moist banks of streams, and moist thickets. Throughout Missouri, where most abundant in the northern, central, and western parts; rare or absent from most of the Ozark section.

Ranges from Ontario to Manitoba and Alberta, south to Ohio, Indiana, Illinois, Missouri, Kansas, Oklahoma, New Mexico, and Arizona.

- 2b. ***Thalictrum dasycarpum*** var. ***hypoglauum*** (Rydb.) Boivin Map 967
Thalictrum dasycarpum f. *hypoglauum* (Rydb.) Steyer. [Steyer.]

Occurs in similar situations and with a similar geographical range within the state as var. *dasycarpum*,

but somewhat less common.

In addition to usually thinner leaves, var. *hypoglauum* has generally longer filaments (4–7 mm. instead of about 4 mm. long) and longer anthers (2.2–3.2 mm. instead of 1.5–2.5 mm. long) than var. *dasycarpum*.

Ranges from Minnesota and South Dakota to British Columbia, south to Louisiana, Texas, and Arizona.

- 3a. ***Thalictrum revolutum*** DC. f. ***revolutum***
 Wax-leaved Meadow Rue, Waxy Meadow Rue
 Map 968

Also known as Purple Meadow Rue.

Thalictrum revolutum DC. [G, BB, P & S, Steyer.]

Occurs in prairies and open ground along roadsides, thickets and openings in woodland. Mostly in the Ozark section of southern and central Missouri and in the eastern half of northern Missouri west to Mercer and Grundy counties.

Ranges from Massachusetts to Ontario, south to Florida, Alabama, Tennessee, and Missouri.

- 3b. ***Thalictrum revolutum*** f. ***glabrum*** Pennell
 Map 968

Scattered in the range of f. *revolutum* and less common.

5. ***Trautvetteria*** Fisch. & Mey. False Bugbane

- Trautvetteria caroliniensis*** (Walt.) Vail
 False Bugbane Map 969
 Flowers around June 1–August.

Occurs in moist, shaded crevices of north-facing limestone bluffs along streams. Known only from bluffs along Jack's Fork and Current River in Shan-

Plate no. 164. 1. *Actaea pachypoda*, $\times \frac{2}{7}$; a. Inflorescence; b. PLATE NO. 164

non County, southern Missouri.

Ranges from Pennsylvania to Kentucky and Georgia; southern Indiana, western Illinois, and southern Missouri.

This is one of the rarest wildflowers of Missouri. It is found at several stations, however, at each of which it is locally somewhat plentiful. One is at Jam-Up Bluff along Jack's Fork of Current River (July 17, 1932, *Steyermark* 7119; July 27, 1898, *Bush* 178), the others along Current River near and north of Emi-

nence. At these stations it is associated with *Parnassia grandifolia*, *Adiantum Capillus-Veneris*, and sometimes *Campanula rotundifolia*, *Galium boreale* var. *hyssopifolium*, and *Zigadenus elegans*. Its corymbiform clusters of white flowers are quite showy. This species has prospered in the author's wildflower garden in northern Illinois during the past fifteen years, where it was started from seed obtained from Missouri specimens. It thrives there in a calcareous rich soil in low, slightly damp woodland.

6. *Aquilegia* L. Columbine

Aquilegia canadensis L. Columbine Map 970

Called Wild Honeysuckle in some sections of the state.

Flowers April-July.

Occurs in the Ozark region usually on limestone bluffs and ledges, elsewhere in rich woods or on steep wooded slopes, occasionally along railroads, and openings in logged areas. Throughout Missouri, where found in all but a few of the extreme southeastern lowland counties and in some of the southwestern counties by the Kansas line.

Ranges from Nova Scotia to Saskatchewan, south to Florida and Texas.

Missouri material may be divided into the following two variations:

- Flowers yellow with red or pink
 6a. *A. CANADENSIS* f. *CANADENSIS*
 Flowers entirely yellow or pale yellow
 6b. *A. CANADENSIS* f. *FLAVIFLORA*

6a. *Aquilegia canadensis* L. f. *canadensis*

Throughout Missouri.

6b. *Aquilegia canadensis* f. *flaviflora* (Tenney) Britt. Map 970

Aquilegia canadensis var. *flaviflora* (Tenney) Britt. [P & S]

Known only from Buchanan (*Broadhead*) and Clay (wooded ravine slopes with limestone outcrops along Dry Creek, Lautenschlager's Farm, T₅₁N, R₃₁W, sect. 13, 3-3½ mi. west-southwest of Missouri City, May 17, 1949, *Steyermark* 67740) counties in northwestern and west-central Missouri. At the Clay County station five plants were seen. One of them was transplanted to the author's wildflower garden in northern Illinois

where it is still growing. Seed from another plant produced a lone one of the resulting progeny with all the flowers pale yellow, while the others had normal red-and-yellow flowers. The lone descendant with the pale yellow flowers comes up each year true to color and has paler green leaves than the normal-colored type, as well as having a yellow-green or pale green stem in contrast to a purplish-red stem of the normal-colored plants.

The forms having the flowers salmon-pink, f. *Phippenii* (J. Robins.) R. Hoffm., or white, f. *albiflora* House, have not yet been recorded from Missouri.

This species was divided by Dr. Munz (*Gent. Herb.* 7: 116-23, 1946) into several varieties based upon variation in size and shape of sepals, length of spurs, and the extent of lobing of the leaflets and degree of division of the basal leaves. According to his interpretation and that of Fernald (eighth edition of *Gray's Manual*) who followed, var. *coccinea* and var. *latiuscula* are the variations found in Missouri, with apparently var. *coccinea* the commoner one encountered having longer sepals 15-20 mm. and oblong-ovate, instead of 10-14 mm. long and ovate or ovate-lanceolate, and with stout instead of slender spurs. Study of Missouri material over a period of years has forced the present author to conclude that the differences suggested by Dr. Munz are not sufficiently correlated or distinct to merit their recognition, and for this reason they are eliminated from consideration in the present work. This is the conclusion, likewise, reached by Dr. Gleason (*New Ill. Fl.* 2: 164, 1952). Plants growing on limestone bluffs and in their crevices are usually shorter-stemmed than those growing away from such habitats, and in some of the habitats in northern Missouri where plants are often found in soil free from rocks the stems are two to three times as tall with a more luxurious appearance. Correlations in sepal, spur, and leaf variations do not appear, however, to be constant nor clearly defined.

7. **Delphinium** L. Larkspur

- a. Pistil or fruit (follicle) 1 to each flower; annuals escaped from cultivation. 1. **D. AJACIS**
- a. Pistils or fruits (follicles) 3 or 5 to each flower; native perennials b
- b. Follicles (fruits) spreading at maturity; stems averaging shorter than the other species, mainly 2-3.5 dm. tall (up to 6-9 dm.); roots short, thickened, tuber-like, fleshy; inflorescence mainly 4-10 cm. long (up to 20 cm.); lower petals (do not confuse with the larger colored petal-like sepals) split into 2; seeds smooth and unwrinkled. 2. **D. TRICORNE**
- b. Follicles (fruits) erect and parallel to one another at maturity; stems tall, mainly 7-20 dm. tall (and as short as 5 dm.); roots elongate, not conspicuously thickened, rather firm; inflorescence mainly 10-30 cm. long; lower petals (do not confuse with the larger colored petal-like sepals) not split into 2; seeds rough or covered with scales or wrinkled even when otherwise smooth. c
- c. Stem glabrous (without hairs) below the inflorescence; seeds not covered with scales, wrinkled but otherwise smooth; rare species found only in southwestern or southern Missouri d
- d. Spring-flowering (May-June); flowers deep blue or blue-purple; leaf-divisions narrow and linear, 3-8 mm. broad; lower stalks (pedicels) of flowers or fruits mainly 2.5-8 cm. long 3. **D. TRELEASEI**
- d. Summer-flowering (July-August); flowers purple, pale blue or whitish with lavender; leaf-divisions broad, lanceolate or wedge-shaped, mostly 10-25 mm. broad; lower stalks (pedicels) of flowers or fruits chiefly 1-2.5 cm. long 4. **D. EXALTATUM**
- c. Stem hairy below the inflorescence; seeds covered with scales, roughened; common species throughout the Ozarks and northern and central Missouri e
- e. Flowers mainly a deep blue or violet color, or mixed blue, lavender, and lilac; seeds covered with appressed scales, slightly winged on the margins; plants chiefly of limestone glades or rocky lime or chert openings of the Ozark and Ozark border region (apparently hybridizes with the following species in paler flowers with more white predominating) 5. **D. CAROLINIANUM**
- e. Flowers mainly white, greenish-white, or mixtures of white with lilac or blue; seeds densely covered with projecting scales, not winged on margins; plants chiefly of prairies, railroad tracks, rocky openings, and open places in northern and western Missouri in the glaciated and unglaciated prairie sections of the state (apparently hybridizes with the preceding species with bluer or more lavender-tinged plants) 6. **D. VIRESCENS**

1. **Delphinium Ajacis** L. Rocket Larkspur
Map 971

Flowers May-September.
Commonly planted as a garden flower and escaped from cultivation along streets in towns, along roadsides and railroad tracks, fields, farmlots, and waste ground. Scattered throughout Missouri.

Native of Europe; introduced and naturalized in North America from Nova Scotia to Minnesota and Montana, south to South Carolina and Texas.

Flowers of this species have blue, purple, lavender rose, pink, or white flowers.

2. **Delphinium tricornes** Michx. f. **tricornes**
Dwarf Larkspur
Map 972

Flowers April-early June.
Occurs in rich or rocky woods, on slopes, valley and ravine bottoms, ledges along bluffs, and banks of streams. Throughout Missouri; absent from the lowland counties of extreme southeastern Missouri, but

to be expected otherwise in every county.

Ranges from Pennsylvania to Minnesota and Nebraska, south to Georgia, Alabama, Arkansas, and Oklahoma.

The flowers are mainly blue or violet or shades of these mixed with white in typical *D. tricornis* f. *tricornis*. In f. *albiflora* Millsp. they are white throughout. The closest approach to an all-white corolla is the collection of Drouet 2854 from Boone County (along lower Brushy Creek, Federal Wildlife area, east of Ashland, May 4, 1936 in Univ. Mo. herb.). However, since the collection has the note 'almost white corolla form,' it cannot be considered typical f. *albiflora*.

Plants of this species are poisonous to stock, and are probably the commonest cause of cattle poisoning in early spring when the green plants are grazed.

3. **Delphinium Treleasei** Bush Trelease's
Larkspur Map 973
Flowers May-June.

Occurs on limestone glades and bald knobs in the White River region and on rocky open limestone exposures and glades elsewhere. Known only from southwestern Missouri circumscribed in a small area including Polk, Cedar, Dade, Greene, Lawrence, Taney, Stone, and Barry counties.

Known only from Missouri; probably in adjacent Arkansas.

This is a handsomely colored plant with deep blue or blue-purple flowers. There is some variation in size of flowers (2.5-3.7 cm. long), in the amount of yellow and brown spotting on the sepals, and the amount of yellow beard present on the petals.

The species has done well far north of its known natural range in the author's wildflower garden in northern Illinois. As long as it is provided with a sunny, open, well-drained, preferably limestone rocky soil free from competition with grasses, there should be no difficulty in getting this attractive species well established.

4. **Delphinium exaltatum** Ait. Tall Larkspur
Map 974
Flowers July-August.

Occurs on limestone or cherty limestone wooded, usually steep slopes of north- or west-facing exposures of hills bordering Current River, Jack's Fork of Current River and tributary streams in Shannon County and South Fork of Spring River in Howell County.

Known only from southern Missouri in Shannon (dry rocky open hillside above Current River, 0.5 mi. below Round Spring, August 8, 1942, Hubricht B 2266; $\frac{1}{2}$ way up west-facing wooded limestone slopes just bordering and below limestone glade along highway 19, T30N, R4W, SW $\frac{1}{4}$ sect. 20, 0.5 mi. southwest of Round Spring State Park, above valley of Spring Valley, July 24, 1955, Steyermark 78915; $\frac{1}{4}$ - $\frac{1}{2}$ way up open west-facing wooded limestone slopes, along Jack's Fork of Current River along south and east side of river, T28N, R5W, sect. 3, 8 $\frac{1}{2}$ -9 mi. [by air] southwest of Eminence, July 25, 1955, Steyermark 78921) and Howell ($\frac{1}{2}$ - $\frac{3}{4}$ way up eroded limestone to cherty limestone steep wooded slopes along South Fork of Spring River, T22N, R8W, sect. 15, 10 mi. [by air] south of West Plains, 5 mi. [by air] northwest of Lanton, June 26, 1955, Steyermark 78760 [vegetative condition only]) counties.

Ranges from Pennsylvania to North Carolina and Alabama, west to Ohio, Tennessee, and Missouri.

At all the above-cited stations the plants were locally frequent to common. At one of the Shannon County stations on west-facing, rather dry slopes, the species was associated with *Agrimonia rostellata*, *Polygala Senega* var. *latifolia*, *Silphium Gatesii*, and *Liatris squarrosa*. At the Howell County station on north-facing slopes it was growing with *Viburnum Rafinesquianum* var. *affine*, *Dirca palustris*, *Solidago arguta*, *Gerardia flava* var. *macrantha*, *Veronicastrum virginicum* f. *villosum*, *Trillium recurvatum*, *Panicum Boscii*, and *Asclepias quadrifolia*.

Plants grown at the author's botanical preserve in northern Illinois from seed collected in southern Ohio have done well in a wooded situation during the past ten years, and have spread through seeding. In such shaded situations the corolla becomes paler lavender.

There is a specimen in the Drury College Herbarium from Bethesda, Greene County, collected May 19, 1887, by J. W. Blankinship, which may be this species, but the early date of flowering suggests a confused label, as the species does not flower until July.

5. **Delphinium carolinianum** Walt. Carolina
Larkspur Map 975
Also called Wild Blue Larkspur.
Flowers May-June.

Occurs on usually limestone and cherty limestone glades, prairies, and rocky openings in woods, also along railroads in prairie habitats.

This species is quite variable in color of flower and pubescence of stem, as well as vigor of plant, and size

PLATE NO. 165

974 *Delphinium exaltatum* (Tall Larkspur)975 • *Delphinium carolinianum* var. *carolinianum* (Carolina Larkspur)975 □ *Delphinium carolinianum* var. *Nortonianum*975 x *Delphinium carolinianum* var. *crispum*976 • *Delphinium virescens* var. *virescens* (Prairie Larkspur)976 □ *Delphinium virescens* var. *Penardi*976 x possible hybrids between *Delphinium virescens* and *D. carolinianum* var. *crispum*

of leaves. The following variations may be recognized in Missouri:

- a. None of the hairs on stem with glands at their tips 5c. *D. CAROLINIANUM* var. *CRISPUM*
- a. Some of the hairs on upper part of stem with glands at their tips b
- b. Hairs on stem rather short, not conspicuous 5a. *D. CAROLINIANUM* var. *CAROLINIANUM*
- b. Hairs on stem long, conspicuous, bunching together in soft tufts 5b. *D. CAROLINIANUM* var. *NORTONIANUM*

5a. ***Delphinium carolinianum* Walt. var. *carolinianum*** Map 975
Delphinium carolinianum Walt. [G, BB, Steyerl.]
Delphinium azureum Michx. [P & S]
 Scattered in the Ozark section of the state.
 Ranges from Florida to Texas, north to Virginia, Missouri, Oklahoma.

5b. ***Delphinium carolinianum* var. *Nortonianum*** (Mackenz. & Bush) Perry Map 975
Delphinium azureum var. *Nortonianum* (Mack. & Bush) Palmer & Steyerl. [P & S]
Delphinium Nortonianum Mack. & Bush
 Known from several counties in the Ozark section, but uncommon. Usually in more acid soils of chert in rocky open woods or bordering oak-hickory or pine-oak woods, also in prairies along railroads, less common on glades.

Known only from Missouri, Arkansas, and Oklahoma.

5c. ***Delphinium carolinianum* var. *crispum*** Perry Map 975
 Occurs usually on limestone glades, rocky openings, and prairies, and along railroads. This is the commonest of the variations in Missouri and is found through-

out the Ozark region for the most part, and the region bordering it on the north to Lincoln, Montgomery, Callaway, Cooper, Pettis, and Johnson counties, locally northward in northeastern Missouri to Monroe and Knox counties.

Ranges from Ohio to Illinois and Missouri, south to Arkansas and Oklahoma.

Ewan (Univ. Colo. Stud. 2: 55-244. 1945) in his revision of *Delphinium* combines the above variations of *D. carolinianum*, believing that the varying types of pubescence and glandularity do not merit recognition. His view may eventually have to be followed, but, pending detailed field and experimental investigations of the variations involved, the present treatment recognizes such variation. Plants lacking glandular hairs and having pale blue or whitish mixtures show intermediate combinations between this and the next species and may represent hybrids.

6. ***Delphinium virescens* Nutt. Prairie Larkspur** Map 976

Flowers May-July.

Occurs in prairies, along railroad tracks, and sometimes on rocky exposures and openings in woods.

Two variations are recognized in this species:
